The calcium salt of this acid ( $C_{10}H_7OSO_3$ )<sub>2</sub>Ca + 2H<sub>2</sub>O, which has been previously described under the names of *asiprol* (this Journal, 1892, 772) and *abristol*, has been found to exert a remarkable preservative influence on wine, entirely preventing as it does, even under the most trying circumstances, the development of acidity, &c. Moreover, Dujardin-Beaumetz and Staekler have shown that the new antiseptic is perfectly harmless to the consumer, even when used in much larger quantities than necessary for the preservation of wine (10 grms. per hectolitre). As regards the legal aspect of the question, it seems probable that the addition of *abristol* to wine must be prohibited if the letter of the law be adhered to. Possibly a limit of toleration may be permitted, as in the case of salt and potassium sulphate (see next abstract).—H. T. P.

*Note on Abristol.* E. Noelling. Monit. Scient. 1894, 2, 257–258.

ABRISTOL, the calcium salt of  $\beta$ -naphthol sulphonic acid,  $Ca(C_{10}H_7OSO_3)_2 + 3H_2O$ , has been latterly employed with excellent results for the preservation of wines. In spite of the complete harmlessness of the product, considerable objection has been raised by the French press, &c. to its use, opposition being offered to the addition of all chemicals, however harmless, in the case of alimentary substances. As the subject is one of those under discussion before the "Comité d'Hygiène de France," the author takes the opportunity to bring forward the evidence in favour of the harmlessness of *abristol* from a hygienic standpoint. The maximum quantity of *abristol* necessary for the preservation of wine is 10 grms. per hectolitre. Dujardin-Beaumetz and Staekler have, however, shown that 6 grms. of *abristol* may be taken internally per diem without any ill-effects. As regards the possibility of noxious decomposition products being formed from *abristol*, the only reaction that need be considered is the possible formation of free naphthol and potassium sulphate. The quantities of these substances obtainable by the decomposition of 10 grms. of *abristol* are 6 and 8 grms. respectively. Potassium sulphate is tolerated by law in wines up to 2 grms. per litre; whilst naphthol is even more harmless than *abristol* itself, and may be taken in doses up to 26 grms. without risk. From these facts it appears that the addition of *abristol* to wines might with advantage replace the usual practice of "plastering," since by the latter operation considerable quantities of potassium sulphate are formed, a substance which has been shown to exert a distinctly unfavourable influence on the human organism.—H. T. P.

*Aeration: Its Effect in Brewing.* L. Briant. Trans. North of Eng. Inst. Tech. Brewing, 1893–94, 3 [2], 23–32.

The value of aeration is now universally admitted, and there are few breweries in which it has not been adopted. Dealing with the contamination side of the question, the author quotes some figures showing the number of micro-organisms contained in the air at various seasons and at different altitudes from the ground. As these micro-organisms include bacteria, wild yeasts, &c., the desirability of preventing infection is obvious; but the means at one time adopted for this purpose—of discarding the coolers entirely, and using only internal refrigerators—are not commendable (and quickly fell out of use) because aeration is reduced to a minimum, and the resulting beers "drop bright" with difficulty.

Aeration is of two kinds, hot and cold. The former is a chemical process, i.e., the oxygen of the air is absorbed and combines with the wort constituents. During the latter, oxygen is mechanically dissolved by the wort. The precise effect of hot aeration, and the manner in which the oxygen is fixed, are not known. But the author disposes of the theory—accepted by many—that certain nitrogenous constituents of the wort are precipitated thereby. Experiments are quoted which show that the nitrogen percentage is practically unaltered by aeration. Aerated wort, however, is always slightly darker in colour, and settles bright readily as compared with non-aerated wort. The latter, in fact, retains a persistent opalescence (due to finely-divided hop-resins) which extends to the resulting beer, causing a turbidity which is difficultly removable, even by finings. Taking into account these facts, as well as Hayduck's researches on the hop-resins, it is probable that the oxygen absorbed combines with the carbohydrate constituents of the wort, and partly with the hop-resins, causing the latter to agglomerate and deposit readily. Hot aeration takes place best at temperatures ranging from 180°–200° F., i.e., when the wort is on the hop-back and early on the coolers. The author regards as practically useless all processes involving the blowing of air through the boiling wort in copper. Although moderate aeration is desirable, over-aeration is probably objectionable, as it appears to result in a loss of hop flavour (Pasteur), and possibly also in loss of antiseptic power of the hop-resins. Moreover, the wort is unnecessarily exposed to the risk of infection.

Cold aeration occurs chiefly on the refrigerators. At this stage the wort becomes almost saturated with dissolved oxygen, the presence of which is necessary, as Pasteur has shown, in order that a vigorous fermentation may be obtained. The oxygen thus dissolved disappears during the early stages of fermentation (8–10 hours after pitching), and is undoubtedly utilised by the yeast.

In the discussion which ensued after the reading of the paper, no points of importance were raised.—H. T. P.

*Hops.* L. Briant and C. S. Meacham. Trans. Inst. Brew. 7, 117–140.

EXPERIMENTS conducted by Hayduck's method show that the deterioration which takes place in hops on keeping is due to the transformation of soft oleo-resin into hard resin, but this change would seem not to be the result of an oxidising action of the atmospheric oxygen.

The amount of resin contained in the same kind of hops at different stages of development and ripening increases with the age of the hop until the hop has attained a degree of brown ripeness, which would militate very greatly against its market value on the ground of appearance. The authors have confirmed their former opinion (this Journal, 1893, 703) that foreign hops have a greater preservative action than English hops, and show that this is due, not to foreign hops yielding a greater proportion of acid to beer than English ones, nor to their containing any materially greater amount of tannin, but to their being richer in total resins and containing a larger proportion of oleo-resin than English hops.

The authors are of opinion that the amount of albuminoids precipitated by the hop tannin during the boiling of wort is very small and has been much over-estimated.

—J. G. W.

*Studies on Secondary Fermentation and "Frets."* H. Van Laer. Trans. Inst. Brew. 7, 55—113.

By cultivating the deposits of English and Belgian beers, which were undergoing secondary fermentation, in wort-gelatin or gelatin and beer, taking, however, the necessary precaution of continuing the cultivation for a sufficient length of time, the author has isolated, in addition to *Saccharomyces cerevisiae*, *Mycoderma cerevisiae* and torulas, ten growths presenting marked differences in their physiological characters which he has made the objects of investigation. The same yeasts were also found in the yeast used for pitching these beers, but to isolate them directly from such a yeast it was first necessary to induce their appearance by fermenting products of starch conversion, previously fermented and freed from alcohol, with this yeast.

A deposit is obtained in this way, after several weeks' forcing, consisting of the secondary forms pre-existent, but microscopically indistinguishable in the pitching yeast. Secondary forms were also obtained direct from ordinary yeast by placing it for eight days on sterilised filter-paper under a desiccator and afterwards cultivating in a very attenuated beer which had been previously fermented and then pasteurised, after the addition of a little maltose. By this method of culture the *S. cerevisiae* forms existent in the yeast reproduce themselves less rapidly than do the secondary forms.

The species of secondary forms isolated in this way were distinguished by (1) their macroscopical aspect, which varied from heavy and clotty to light and flocculent; (2) the limit-attenuation to which they gave rise in boiled worts, which showed considerable variation; and (3) their fermentative energy or the relative rate of destruction of carbohydrates which they produced in the same wort under identical conditions.

With regard to their microscopical aspect, the *S. cerevisiae* forms retained their original round form during all the phases of fermentation, while the *S. ellipsoideus* and *S. Pastorianus* forms showed considerable polymorphism dependent on the stage of fermentation and the medium in which it was conducted.

Experiments were conducted on the fermentation of wort by means of isolated species, both singly and in mixture, and the author arrives at the conclusion that when dry hops are added to a beer at racking (1) the after-fermentation will show itself after a more or less extended period, irrespective altogether of the nature of the yeast used for pitching; (2) if the primary yeast is mixed with even minute quantities of secondary yeasts, the after-fermentation always shows itself and with greater intensity than when the beer has only been pitched with the primary yeast; and (3) that the intensity of the fermentation depends upon the nature of the yeasts mixed with the principal yeast. The author explains the turbidity produced in beer by "frets" as being due to the coefficient of reproduction, i.e. the ratio of the number of cells produced to the matter fermented, of yeasts of the *ellipsoideus* and *Pastorianus* types being greater than that of *S. cerevisiae*.

Fermentations conducted without the addition of dry hops at racking have established the following conclusions:—

(1.) The exclusive use of certain types of yeast may give rise to an after-fermentation, which must be regarded as a continuation of the primary one. This after-fermentation is, however, too vigorous and is accompanied by a too great reproduction of yeast to be applicable commercially.

(2.) Every system of yeast formed by one or more races of a similar type and of very small quantities of a yeast having a lower limit of attenuation may give rise to after-fermentation, in which instance the attenuation obtained at racking is practically that which would have been obtained by fermenting with the preponderating yeast only, whilst the limit-attenuation will be that of the lowest type of the system of yeasts.

(3.) An after-fermentation can also be obtained by introducing into a yeast or mixture of yeasts, the pace of fermentation of which is rapid, a large quantity of a slower yeast, by which means the attenuation at racking will be prevented from attaining the limit corresponding to the rapid yeast. The after-fermentation is then produced by virtue of the difference existing between the attenuation at

racking and that corresponding to the limit-attenuation of the system of yeasts used.

Beers fermented with certain mixtures of *Saccharomyces* possess a greater immunity as regards wild yeasts and bacteria than do beers which are the result of single-race fermentation.

*Pure Cultivation Yeast and the Use of Antiseptics, especially of Fluorine Compounds, in the Distilling.* A. Claus. Zeits. für Spiritus-ind. 16, Ergänzungsheft, 91.

AFTER a careful discussion of the results of himself and others, the author draws the following conclusions:—(1.) The introduction of pure yeast in the manufacture of spirit is a decided advance, as antiseptics are not able to insure a pure culture nor the destruction of disease ferments. (2.) True pure culture is only attainable by Hansen's method of starting from a single cell. (3.) Effront's proposal to purify the yeast by hydrofluoric acid is not certain to effect its purpose of enabling the culture yeast to destroy the disease ferments. (4.) The advantages of the Hansen method, which have been proved in brewing, are equally valid in spirit manufacture. (5.) The introduction of the pure culture system does not exclude the use of antiseptics, which are still necessary in certain directions. (6.) With the employment of pure cultures, the use of disinfectants in cleansing of vessels, &c. is even more necessary than hitherto. The author considers fluorine compounds the best disinfectants for these purposes. (7.) The use of disinfectants with the yeast, mash, &c. is still necessary, as in spirit manufacture the mash is more susceptible to bacterial infection than is the case with the hopped mash of the brewery. Diastase especially needs the protection of antiseptics. (8.) The mode of working will be modified where pure culture is introduced, as less impurities are introduced into the mash and the latter becomes more resistant to outside influences. (9.) Hydrofluoric acid is of great value in helping the pure yeast to resist the harmful influence of acidifying ferments, &c., both during fermentation and during the continuous yeast culture. This beneficial influence is not, however, as far-reaching as Effront states it to be. (10.) Hydrofluoric acid exercises a specific physiological action on yeast and if employed with care, may be a useful stimulant for the yeast. It must be remembered, however, that under certain circumstances this acid may also act as a stimulant to the disease ferments; and an exact knowledge of the culture and disease yeasts, and of the other organisms met with in spirit manufacture, is necessary before a really rational and complete use of the hydrofluoric method is possible.

—L. T. T.

## PATENTS.

*An Improvement in the Manufacture of Beer.* J. Pikhart. Mahrisch-Schoenberg, Moravia. Eng. Pat. 10,132, May 20, 1893.

THIS invention relates to the application of a preparation of the fruit of the carob tree (*ceratonia siliqua*) in brewing, with the object of imparting a pleasant aroma and giving greater body to beer; also to mask the rapid bitter flavour and render the beer better fitted for keeping and more wholesome. The fruits are treated with warm water, and are washed and dried at about 35° C. until they present a brownish colour, and the juice of the fruit when the latter is broken is dark red. The dried fruits while still warm are cut into pieces and may be stored or added directly to the mash in the proportion of about 2.5 kilos. to a hectolitre of ordinary beer.—A. R. L.

*An Improved Still or Apparatus for Distilling Spirits and all kinds of other Liquids.* G. Morris and W. Edney, both of Bristol. Eng. Pat. 16,063, August 25, 1893.

See under I., page 504.

*Improvements relating to the Saccharification of Wort or the Malt, and to the Extraction and Subsequent Treatment thereof in Brewing, Distilling, and in the Manufacture of Maltose, Syrups, and other Extracts, and Apparatus therefor.* G. de Geyter, Monseron, Belgium. Int. Pat. 6168, March 22, 1894.

THE process claimed in this specification comprises the following clauses:—(1.) The continuous diastatic saccharification of the amylaceous materials obtained by uninterrupted circulation within appropriate vessels (see figure). (2.)

The exhaustion or extraction and continuous washing of the malt and hops. (3.) The coagulation of the nitrogenous materials of the wort by oxidation in a tubular apparatus, followed by the purifying of the wort by separation of the nitrogenous coagulated materials by cold filtration and subsequent reheating during the boiling process, and without interruption. The invention of the apparatus (see figure) for carrying out the above process is also claimed. It consists of three troughs, namely, a "resting trough" R, a "saccharifier" S, and a "resting trough" R' for the

saccharifier. Each of these is provided with "moistening," "working up," and "propelling" gear so that the diastatic action may proceed continuously. There are also washing and exhausting batteries for the returns and hops, V to V<sup>1</sup> and V<sup>2</sup> to V<sup>3</sup>, having false bottoms, in which the water arriving over the most exhausted returns or hops passes successively over the gradually richer returns or hops so as to produce a complete exhaustion. Lastly, the combination of an aerator tube t<sup>(1)</sup>, serving to bring about the coagulation of the nitrogenous matters of the wort, with a heat interchanger M and a filter F for separating the coagulated nitrogenous matter during the boiling of the wort.—A. R. L.

Skimmed milk, exposed in a eudiometer to the action of oxygen ozonised by the passage of an electric spark, became acid and coagulated. He now finds that other oxidising agents, such as hydrogen peroxide, bromine water, potassium permanganate and bichromate, have a like effect. The effect of rennet is not, on this account, necessarily to be considered one of oxidation, being more probably due to precipitation of the casein by lactic acid arising from milk-sugar acted on by the rennet. He suggests the use of hydrogen peroxide in place of rennet for cheese-making.

—B. B.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY AND WATER PURIFICATION, DISINFECTANTS.

### (A).—CHEMISTRY OF FOODS.

*The Curdling of Milk.* M. W. Hes. School of Mines Quarterly, 15 [2], 1894, 105—108.

In 1877 the author published the following observation in the Boston Journal of Chemistry, 12 [6]:—

*The Carbohydrates of the Fruit of the Kentucky Coffee-Nut Tree (Gymnocladus Canadensis).* W. E. Stone and W. H. Test. Amer. Chem. J. 15, 660—663.

THE Kentucky coffee-nut tree occurs in fertile soils in the west and south-west of the United States, and is closely related both to the common thorny or honey locust (*Gleditsia*) and to *Ceratonia siliqua*. The fruit consists of a leathery pod 3 to 6 ins. in length, and containing from two to six brown, oval and very hard seeds, which are embedded in a greenish waxy gum. The dry matter of the gum contains about 15 per cent. of saccharose, and almost as much glucose; it is free both from galactose and from starch. The insoluble gum of the fruit which remains after extracting the fresh gum with alcohol is partially hydrolysed when treated with dilute sulphuric acid, the products of hydrolysis being dextrose and a pentose, probably arabinose.

It is questionable whether these are derived from separate mother-substances in the gum or from an individual substance.—C. A. K.

*Manufacture of Oil and Food from Pea Nuts.* United States Consular Reports, 1894, **44**, 683.

See under XII., page 530.

*Natural Oxycelluloses. I. Celluloses of the Gramineæ.* C. Smith. Proc. Chem. Soc. 1894 [137], 89.

THE "celluloses" of esparto and the cereal straws, as isolated by the well-known processes of the paper-maker, were further purified, and (1) their ultimate composition, (2) the amount of furfural obtained on boiling with aqueous hydrochloric acid (1.06 rel. dens.) were determined.

These "celluloses," were found to be oxycelluloses, and, since they do not give the reactions characteristic of the pentoses, they are of the type of those obtained by Cross and Bevan by regulated oxidation of the normal celluloses (Ber. 1893).

Such oxycelluloses being widely distributed in nature, it becomes important to study their physiology. A course of systematic observations has therefore been undertaken on the germination and growth of the barley plant in relation to the composition and constitution of its permanent tissue ("cellulose").

It has already been observed that, by germination in the dark and growth of the sprouts (etiolated) until the endosperm is nearly exhausted, there is a considerable increase in the furfural-yielding constituents (60–80 per cent.), the early material of the tissue giving 5 per cent. furfural, and at the same time no pentose reaction, which proves it to be an oxycellulose. The results are still more marked in the case of the tissues of plants grown in the light. In the discussion following, Mr. Warington hoped that the authors would continue this investigation, as the subject was of much importance in relation to the digestibility of animal food. They had already established the important fact that the production of furfural can no longer be utilised for the estimation of the pentoses, since the oxycelluloses also furnish this compound.

*The Use of Lead Pipes for Conveying Water.* M. T. Lecco. Chem. Zeit. **17**, 1431.

See under XXIII., page 547.

## PATENTS.

*A New or Improved Method of Improving the Quality of Damaged or other Coffee.* A. Brongier, Munich, Germany. Eng. Pat. 8270, April 24, 1893.

THE inventor's claim is one of improvement of the coffee by roasting the beans with an extract containing caffeine, which extract is obtained by boiling new unroasted shells or the pulp of the coffee berries, or coffee leaves, or leaves of the cocon, kola, mathé, or tea. The extract is only added at the moment when the outer layers of the beans begin to give off volatile oil and develop a bluish smoke. Sea-damaged or other coffee of inferior quality is soaked in lime-water previous to the roasting process. Any excess of lime is removed by washing.

Whatever roasting apparatus is used, it must be constructed so as to allow of a periodical insertion of a tube into its roasting drum, for instance, through the hollow axis, to that point where the beans begin to swell and get mellow. The extract containing the caffeine is then sprayed over the beans by means of a distributing apparatus.—L. de K.

*Apparatus for the Artificial Production of Chalybeate Water.* O. March, London. Eng. Pat. 9362, May 10, 1893.

See under XI., page 529.

*Process for Preserving Milk and Cream for a Length of Time, rendering it suitable for Lengthy Transit.* W. F. E. Case, Copenhagen, Denmark. Eng. Pat. 15,161, August 8, 1893.

MILK, which should be quite fresh, is put into suitable containers and mixed with pieces of already frozen milk from the same or a previous milking. The vessel is then generally closed, but in a pure atmosphere it may be left open. The pieces of frozen milk remain floating on the surface, keeping the milk for a time at 32° F. During the gradual melting the liquid is thus kept in a state of continual motion, which prevents the rising of the cream. If the container is large enough to hold 80 or 100 gallons of milk and a sufficiency of frozen milk, and if it be packed in a layer of sawdust 1 or 5 ins. thick, the milk may be, as a rule, kept quite fresh for two or three weeks.—L. de K.

*Improvements in the Treatment of Pepper.* M. Kirchberger, London. Eng. Pat. 16,941, September 8, 1893.

THE inventor claims to have made an improvement in the bleaching of pepper, chiefly by using alum.

After any dust has been separated from the pepper by winnowing, it is placed in water and any grains that float are rejected. The grains which sink are removed and watered at intervals until the outer coverings are rotten. The pepper is then placed in an iron pan and sprinkled with alum or a solution of the same, and trodden under foot until the husks and the black oily matter have been removed. After thoroughly washing with water, the grains are placed in a solution of chloride of lime mixed with alum or a little sulphuric acid. To remove excess of chloride of lime, the pepper is once more rinsed in alum water. In the treatment according to this invention of commercial white pepper coloured with lime, the latter must be first removed by treatment with dilute acetic or some other weak acid.

—L. de K.

*A New or Improved Meat Extract.* Communicated by J. H. Niemann, Warracknabeal, Australia; R. F. Macloskey, Manchester. Eng. Pat. 1170, January 19, 1894.

THE inventor claims to have prepared a superior meat extract by expressing the juices of raw lean meat and evaporating them to a thick consistency or to dryness, after first adding about one eighth part of culinary salt. Before packing the extract for sale and use, it is mixed with about an equal bulk of Liebig's extract of meat or any other similar preparation; also with pepper sauce if desired.

The beef, or other suitable meat, should be freed from fat as far as practicable before being pressed out.—L. de K.

## (B.)—SANITARY CHEMISTRY AND WATER PURIFICATION.

*The Use of Lead Pipes for Conveying Water.* M. T. Lecco. Chem. Zeit. **17**, 1431.

See under XXIII., page 547.

*Experiments on the Disinfection of Town Sewage with Sulphuric Acid.* M. Ivanoff. Proc. Inst. Civil Eng. **115** [1], 42–43; and Zeits. für Hygiene, 1893, 86.

THE fact that the cholera bacillus displays an intense susceptibility to the action of acids was known to its discoverer, for Dr. Koch pointed out that in the acid secretions of the stomach these bacilli speedily lose their vitality. The

subsequent experiments of Kitasato have shown that very minute additions of sulphuric and hydrochloric acids to bouillon cultures destroy cholera germs in the course of a few hours; and, lastly, Messrs. Stutzer and Burri have studied exhaustively the effect upon these organisms of very dilute solutions of sulphuric acid. At the suggestion of Professor Pfuhl, the author undertook to investigate the action of dilute sulphuric acid upon cholera bacteria when present in sewage water. From the inception of his experiments he surmised that under these conditions the acid must be used in a more concentrated form than in above cases, because the sewage water invariably contains substances which would combine with the acid, and would thus, to some extent, neutralise its effects. It was, however, ascertained that the additional amount of acid rendered necessary on this account was but trifling. The samples of sewage water were derived both from the Berlin and the Potsdam sewers, and were infected alternately with pure cultures of the cholera bacillus and with the fresh dejections of a cholera patient. The acid in the case of the Berlin sewage water was used in three degrees of strength:—(1) as a 0.02 per cent. solution; (2) as a 0.04 per cent. solution; and (3) as a 0.1 per cent. solution. The conditions under which the analyses were made are fully described, and the author availed himself of microscopic observations, as well as bacteriological tests. Four parallel series of experiments were carried out, and the results were in every case identical. The Potsdam sewage, which is three times as concentrated as that of Berlin, was treated with stronger acid, viz., with 0.04, 0.06, 0.08, and 0.12 per cent. solutions. It was found that in the case of the Berlin sewage, the 0.04 per cent. solution of acid was fatal to the cholera bacilli, but that with the stronger sewage water of Potsdam, the amount of acid needed was that present in the 0.08 per cent. solution. It is pointed out that whereas, previous to treatment, the sewage water was faintly alkaline, the sample to which 0.08 per cent. of acid had been added had a strongly acid reaction to litmus paper, and that such reaction may be regarded as an indication that the necessary dose of acid has been employed. This treatment is, with the exception of the use of lime, the cheapest system that can be adopted.

*Experiments concerning the Action of Peat Dust upon the Bacteria of Cholera and Typhoid Fever.* C. Fränkel and E. Klipstein. *Zeits. für Hygiene*, 1893, 333; and *Proc. Inst. Civil Eng.* 115 [1], 44–45.

From certain researches by Schröder, it has become evident that, in addition to its properties as a disinfectant, peat possesses the power of destroying the cholera vibrios, though certain other species of bacilli prove themselves more capable of resisting its influence. The authors have conducted a series of tests with two descriptions of peat, one of which had a strongly acid reaction, the other was more feebly acid. Samples of each kind of peat, both sterilised and non-sterilised, were added to cultures of cholera, typhoid fever, and other germs, and the results are set forth in tables. It is deduced that in from 2½ to 5 hours the comma bacillus is destroyed by the addition of peat dust; but exposure to this substance for only one half or one hour will sensibly diminish its vitality. The cholera vibrios may retain their vitality for as long as 14 days in a mixture of peat dust with urine; but, as a rule, they are destroyed at the end of a week, or, in very acid urine, even after only one day. Mixtures of peat with various substances valuable in agriculture (kainit and superphosphates) were also tested by the authors; kainit was found to be wholly devoid of influence upon the cholera bacteria, while both kinds of superphosphate examined proved themselves to be possessed of marked effect in augmenting the germicide powers of peat. Investigations specially undertaken to determine upon what properties in the peat this action depended, demonstrated that its influence was due to the acids therein contained, and led to the conclusion that, in order to increase the efficiency of the peat to the utmost, care must be taken to intensify, as far as possible, this acid reaction by artificial means. Under all circumstances, where a dry system is unavoidable, as, for instance,

in the case of isolated buildings, hospitals, barracks, &c., the use of dried peat may be confidently recommended as furnishing a safe, cheap, and reliable system of dealing with excreta. (See this Journal, 1893, 994.)

## PATENTS.

*A New and Improved Method of Treating Sewage by Means of Ferric Compounds.* R. C. Tanner, Chester. Eng. Pat. 9063, May 6, 1893.

SEWAGE, when not already alkaline, is treated with milk of lime, chloride of lime (calcium hypochlorite), and with solution of ferrous sulphate crystals. But if the sewage is already alkaline, the lime may be omitted.—E. S.

*Improvements in Apparatus for Softening and Purifying Water.* A. Smith, Camberwell. Eng. Pat. 14,195, July 22, 1893.

THE water to be softened is caused to flow through the channels of a mixing cistern, where it meets with the reagent, such as lime or the like, and becomes thoroughly mixed before passing out into the softening cistern, formed with a central entrance funnel, which discharges the water into the cistern where the softening process is completed; the water finally escapes by rising and flowing over the edge of a discharge gutter placed round the inside of the cistern. The process of softening in the mixing cistern may be accelerated by heating the water as it flows through the mixing channels.—E. G. C.

### PATENT.

*A Superfatted Biniodide of Mercury Soap.* C. R. Illingworth, West Kensington, London. Eng. Pat. 12,884, July 1, 1893.

See under XII., page 531.

## XIX.—PAPER, PASTEBOARD, Etc.

*Discoloration of Papers made from Sulphite "Cellulose."* E. Muth. *Dingler's polyt. J.* 291, 235.

THE author has made careful observations upon the discoloration of papers made from bleached sulphite pulp (with addition of the usual rosin size), and after eliminating all other possible causes, concludes that the discoloration is the result of chemical changes in the "cellulose" itself. Having concluded from superficial observations on the liquors obtained as by-products of the pulp manufacture, that these contain "tannins," the author made experiments upon solutions of pyrogallol acid and other phenolic compounds applied to papers, which he finds produce a rapid discoloration. He concludes that such compounds are present in the bleached pulp and are the immediate cause of the discoloration of the papers in question.—C. F. C.

*Spots in Paper.* *Mitth. Königl. tech. Versuchs.* 11 [5], 260.

A YELLOWISH paper which had been attached by means of starch paste to ordinary cardboard made from mechanical wood pulp showed a number of sharply defined and unsightly spots, and a sample, together with some of the pieces of the paper, was submitted to the Institute. After an experiment had been made showing that the starch paste was not responsible for the spots, a piece of the paper was treated with an acid solution of potassium ferrocyanide, when a number of blue spots made their appearance over

the whole surface. When the paper and cardboard were submitted to the same test, the paper side showed similar spots, whilst the cardboard remained unaltered. A slight difference, however, was noticeable in the spots, those on the original paper being sharply defined, whilst those on the paper attached to the cardboard were in part surrounded by a pale blue halo.

The paper was then separated from the cardboard by soaking in water, and the two faces which had been stuck together were treated with the ferrocyanide solution. Both the paper and the cardboard showed spots, but the cardboard only in the places where it had been in contact with the spots of the paper, whilst the back of the cardboard showed no iron reaction. It was therefore fair to conclude that the spots were due to the presence of iron in the water used in the manufacture of the paper. These spots coming into contact with the starch, a small quantity of the iron passes into solution, and as a result of subsequent pressure, the spots appear surrounded by a halo. At the same time the softening of the spots under the influence of the starch paste explains their partial transference to the inner side of the cardboard.—E. G. P. T.

#### PATENTS.

*An Improved Paper or Textile Fabric and Methods of and Apparatus for producing said Paper or Fabric.* S. Wheeler, Albany, U.S.A. Eng. Pat. 9827, May 16, 1893.

THE object of the invention is to produce a paper or other fibrous material permanently wrinkled, and having on its surface distinct figures or ornamentations, such as diamonds or stars. Such wrinkled material is very advantageous in the production of ordinary "sanitary" paper, as it presents a corrugated or uneven instead of the usual surface. The improved product may be obtained either by operating upon material already manufactured or upon material in the process of manufacture. In the first instance the fabric is damped at suitably situated spots by touching it with a damping device. It is then dried, preferably by artificial heat. The damped spots, during the drying, cause the adjacent portions to form into permanent wrinkles, which, unlike the indents formed by folding, crimping, &c., remain absolutely permanent.

In the second instance, the wet paper, after it leaves the forming machinery, is dried in varying spots or lines and at different points, by passing the wet web over a series of heated surfaces so formed as to dry the web at certain points only, leaving the intervening spaces to be dried afterwards. Suitable machinery for producing these results is described and claimed.—E. G. P. T.

*Improvements in the Manufacture of Cellulose.* C. Kellner, Vienna, Austria. Eng. Pat. 24,287, December 16, 1893.

THE process consists in treating wood or other plant substances with hydrolysing or oxidising agents, such as nitric oxide, nitrous, hyponitrous, hydrochloric, and chlorous acids in the gaseous state. The plant substances, previously damped, having been exposed for some time to the action of the acid vapours in a suitably-constructed vessel, are treated with hot or cold water, then subjected to a mechanical treatment in a breaking engine, and subsequently treated with an alkaline solution in order to dissolve the by-products. Finally, they are subjected to violent agitation in a beater, so as to cause the cells separated by the previous treatment to become thoroughly and uniformly intermingled.—E. G. P. T.

*Improvements in the Manufacture of Paper for Bank Notes, Securities, and the like.* C. Battner, Eppendorf, and F. Will, Königsfeld, Germany. Eng. Pat. 3453, February 17, 1894.

FOR the purpose of this invention a fine, transparent, open-mesh fabric made of slender but strong threads is passed into paper pulp, made from the best raw materials, while such pulp is moving over the wire in its passage from the stuff-vat to the couch rolls and before it reaches the latter. The fabric may be plain or with designs in it. In this state the fabric, lying flat upon the wire, is encompassed on all sides with pulp and passes through the couch rolls, whereupon an intimate combination takes place between and through the meshes of the fabric. It is claimed for the paper thus produced that it offers an absolute bar to imitation and falsification, and that it possesses a high degree of tenacity and durability.—E. G. P. T.

#### XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*The Volatile Oil of Rowan-berries, Parasorbic Acid, and its Isomerism with Sorbic Acid.* O. Doehner. Ber. 27, 344—351.

THE fruit of the rowan tree (*Sorbus aucuparia*), or mountain ash, contains, besides malic acid, a volatile weak acid boiling at 221°, and converted into an i-omeric strongly marked acid by treatment with caustic alkalis or concentrated sulphuric acid (A. W. Hofmann). The former has been usually known as *parasorbic acid*, and the latter as *sorbic acid*. The author finds as the result of his experiments that parasorbic acid is not a true acid at all, but a lactone derived from either  $\gamma$ - or  $\delta$ -oxyhydro sorbic acid, and indicated by one of the two formulæ—

whilst sorbic acid is represented by the formula—

Parasorbic acid takes up only two atoms of bromine, whilst sorbic acid unites with four; the latter neutralises the appropriate quantity of alkalis on titration, whilst the former only neutralises about a tenth part of that amount. Parasorbic acid when dissolved in alcohol and treated with hydrochloric acid gas, furnishes the ether of sorbic acid, boiling at 195°; this affords a better way of producing sorbic acid (by saponification of the ether) than the action of alkalis. One gram. of sorbic acid administered to a small dog produced no notable effect, whilst the same quantity of parasorbic acid produced emesis and salivation, but no other marked poisonous action. The quantity of parasorbic acid contained in mountain ash berries is about the same whether they are half-ripe or wholly so, but the green berries do not yield it at all; these, on the other hand, contain malic acid, which disappears as ripening progresses, yielding sorbite,  $\text{C}_6\text{H}_{14}\text{O}_6$ , and sorbinose,  $\text{C}_6\text{H}_{12}\text{O}_6$ , as alteration products.—C. R. A. W.

*Aconitine.* M. Freund and P. Beck. Ber. 27, 433—436.

THE authors have examined the crystallised alkaloid manufactured by E. Merck, of Darmstadt, with results differing somewhat from those of other observers who have previously operated with *A. napellus* roots. They regard it as identical with the alkaloid examined by Alder Wright, and subsequently by Dunstan, but obtained numbers leading to the formula,  $\text{C}_{34}\text{H}_{45}\text{NO}_{11}$ , or more probably,  $\text{C}_{34}\text{H}_{47}\text{NO}_{11}$ , instead of  $\text{C}_{33}\text{H}_{43}\text{NO}_{12}$ . As stated by Ehrenberg and Purfürst it hydrolyses into acetic acid and a new base; this yields crystallisable salts; the hydrobromide melts at 282°, and the hydrochloride at 217° or 270°, according

as it is crystallised from water or from hydrochloric acid. The authors regard this base as indicated by the formula  $C_{22}H_{41}NO_{11}$ ; and as identical on the one hand with the "pieraconitine" isolated by Groves and found by Wright to be indicated by the formula  $C_{31}H_{45}NO_{10}$ ; and on the other hand, with the "isaeconitine" of Dunstan, regarded by him as  $C_{33}H_{47}NO_{12}$ ; accordingly they designate it *pieraconitine*, the relationship of pieraconitine to aconitine being represented by the equation—

i.e., aconitine being acetylpieraconitine. By further hydrolysis benzoic acid is formed, and a new base, apparently identical with the "aconine" of Alder Wright, this being developed from pieraconitine in virtue of the reaction—

Alder Wright, however, found the formula,  $C_{26}H_{39}NO_{11}$ , whilst Dunstan found  $C_{27}H_{41}NO_{11}$ . Hence aconitine is acetyl-benzoyl aconine,  $C_{25}H_{39}NO_9(C_7H_5O)(C_7H_5O)$ .

—C. R. A. W.

*Aconitine.* W. R. Dunstan. Ber. 27, 664.

THE author and his collaborateurs have previously shown that aconitine furnishes acetic acid on heating, and that consequently it is to be regarded as acetyl-benzoyl-aconine, as recently shown by Freund and Beck.—C. R. A. W.

*Aconitine.* M. Freund and P. Beck. Ber. 27, 720—733.

IN continuation of their experiments on crystallised aconitine prepared from *A. napellus* roots by E. Merck, of Darmstadt (this Journal, *supra.*), the authors have found that the alkaloid examined by them gives the same crystallographic measurements as were found by Dunstan; but instead of yielding numbers on analysis agreeing with his formula  $C_{33}H_{45}NO_{12}$ , they obtained values leading to the formula  $C_{34}H_{47}NO_{12}$ ; these values are close to those obtained by Alder Wright for "apo-aconitine" (derived from the alkaloid  $C_{25}H_{43}NO_{12}$ , examined by him, by removal of the elements of water) and for "japaconitine" (from Japanese aconite roots). On the other hand, Jürgens deduced from his analyses the formula  $C_{33}H_{45}NO_{12}$ , and Ehrenberg and Purfürst the formula  $C_{27}H_{43}NO_{11}$ . These latter found that four methoxyl groups were present, as methyl iodide to the corresponding extent was formed on treatment with hydriodic acid. The gold salt from Merck's aconitine melted at  $134-135^\circ$  when prepared by treatment in contact with alcohol, but at  $152^\circ$  after heating so as to drive off alcohol and render anhydrous, in these respects corresponding with different modifications of aconitine aurochloride described by Dunstan. The hydrobromide dried at  $100^\circ$  melted at  $163^\circ$ . On boiling with water aconitine hydrolyses in two ways, partly forming acetic acid and pieraconitine,  $C_{22}H_{41}NO_{11}$ , and partly forming acetic and benzoic acids and aconine,  $C_{15}H_{35}NO_9$ . Pieraconitine, when heated with alcoholic potash, similarly forms benzoic acid and aconine; and on treatment with acetic anhydride furnishes an acetyl derivative, apparently only isomeric and not identical with aconitine, since it melts at  $255-256^\circ$ . The relationships of the different alkaloids examined are expressed by the formulae:—

—C. R. A. W.

*Recent Developments in Pharmaceutical Chemistry with Special Reference to Medicaments obtained by Chemical Synthesis.* Hugo Erdmann. Zeits. ang. Chem. 1893 [13], 379—382.

THE suitability of a chemical substance for pharmaceutical purposes depends upon a variety of circumstances. It should be capable of exerting physiological action, which should be limited definitely to certain parts or functions of the entire organism. It should, as a medicament, be capable of healing unsound organs with the least possible collateral effect upon those which are sound. It should act promptly and energetically and yet not endanger life. The condition is also important, that after long use its efficacy remain unimpaired, and that no toxic phenomena develop themselves. The question naturally follows: "On what does the poisonous quality of a chemical substance depend?" for it is found that the bodies suited as medicaments as a rule occupy a transition position, or one midway between the actually poisonous and the inert elements and compounds. Of the different compounds of one and the same element, the most unstable are usually the most poisonous, as may be observed in the following series of nitrogen compounds in which poisonous quality regularly increases as we pass from left to right:—

Nevertheless both valency and mode of linking of the elements play an important part:—

Harmless.....  $CO_2$   $H_3PO_4$  .....  $KCl$  .....  $MnCl_2$   
Poisonous.....  $CO$   $H_3PO_3$   $As_2O_3$   $KClO_3$   $CrCl_3$   $KMnO_4$   
Very poisonous.  $C_2H_2$   $P$   $AsH_3$  .....  $K_2CrO_4$  .....

Those compounds are especially suspicious, which exert oxidising or reducing action, and thus disturb the functions of the organism. Hence all elements act as strong poisons which furnish several series of stable compounds, easily passing one into the other. Thus arsenic, mercury, thallium, tin, and copper. In one group of similar elements the toxicity steadily increases with increasing atomic weight (see Type I.), in another, however, it decreases steadily (see Type II.).

Type I. . . . .	Group VIa.	O	S	Se	T	
Type II. . . . .	Group VIb.	Cr	M	W	U	
Type III. . . . .	Group V.	N	P	As	Sb	Bi

In the second type, the maximum of toxicity in this series, is attained only in certain nitrogen compounds (alkaloids, &c.), whilst e.g. in the case of the hydrogen compounds  $AsH_3$ ,  $PH_3$ ,  $NH_3$  the toxicity from arsenic onwards, again diminishes. Thus we seem to encounter a kind of contrary motions of certain laws, and this fact would appear to be accounted for in the expression of the following law: *that the toxicity of a chemical element is approximately inversely proportional to its frequency of occurrence in the earth's crust.*

The frequently occurring elements are all more or less suited for medical uses, but the strongest action can only be conferred upon them by union with certain of those elements of rarer occurrence, among which only few are to be found which are non-poisonous.

A table is given exhibiting the periodic functions of the elements and their relative physiological activities.

Ethyl, in opposition to methyl and the higher homologues, exerts a favourable nerve-quieting action. This, it is suggested, may be merely attributable to the fact of the habit acquired by mankind of partaking of alcoholic beverages. It is only possible to register it as a singular fact, that whilst the entrance of  $NH_3$  or  $OH$  converts aromatic compounds into poisonous substances, the simultaneous presence of these two salt-forming groups in the para-position to each other, means the mutual paralysis of their physiological properties, that a relatively harmless compound (para-amidophenol) is obtained, in which, moreover, the aggressive properties of both salt-forming groups by further union of the amido group with an acid residue and of the hydroxyl with alkyl (especially with the active ethyl group) may be further diminished, as, for example, in the formation of phenacetin

Strongly acid groups deprive organic compounds of almost all physiological effect; thus, the acid dyestuffs are, almost without exception, non-poisonous, and the sulphonated medicaments become for the most part inactive.

The presence of a carboxyl group sensibly diminishes physiological properties, but is not able to remove them in the case of stronger poisons.

## Poisonous Mother-substance.

Phenol,  
Pyrogallol,  
Guaiacol.

## Non-poisonous Carboxylated Substances.

Salicylic acid,  
Gallic acid,  
Guaiacol-carbolic acid.

TABLE OF THE MOST IMPORTANT MEDICAMENTS.

Trade Name.	By whom introduced.	Scientific Name.	Formula.	Active Elements or Groups.
<i>A.—Hydrocarbons, Alcohols, Phenol Derivatives.</i>				
Pental.	v. Merz.	Trimethylethylene.	$\begin{array}{c} \text{CH}_3 \\ \text{CH}_3 \end{array} \text{C} = \text{C} \begin{array}{c} \text{CH}_3 \\ \text{H} \end{array}$	Two tertiary carbon atoms.
Anylene hydrate.	v. Merz.	Tertiary amyl alcohol.	$\begin{array}{c} \text{CH}_3 \\ \text{CH}_3 \end{array} \text{C} \begin{array}{c} \text{C}_2\text{H}_5 \\ \text{OH} \end{array}$	A tertiary carbon atom with an ethyl group.
Salol.	Sabli.	Salicylic phenyl ester.	$\begin{array}{c} \text{C}_6\text{H}_5 \\ \text{C}_6\text{H}_5 \end{array} \text{C} \begin{array}{c} \text{CO}_2\text{C}_6\text{H}_5 \\ \text{OH} \end{array}$	Salicylic acid, phenol.

*B.—Substances containing Sulphur.*

Sulphonal.	Kast.	Diethylsulphone dimethyl-methane.	$\begin{array}{c} \text{CH}_3 \\ \text{CH}_3 \end{array} \text{C} \begin{array}{c} \text{SO}_2\text{C}_2\text{H}_5 \\ \text{SO}_2\text{C}_2\text{H}_5 \end{array}$	A tertiary carbon with two ethyls.
Trional.	Baumann and Kast.	Di-ethylsulphone-methyl-ethyl-methane.	$\begin{array}{c} \text{CH}_3 \\ \text{C}_2\text{H}_5 \end{array} \text{C} \begin{array}{c} \text{SO}_2\text{C}_2\text{H}_5 \\ \text{SO}_2\text{C}_2\text{H}_5 \end{array}$	A tertiary carbon with three ethyls.
Saccharine.	Adamo and Mosso, Salkowski, Leyden.	<i>o</i> -sulphobenzoic imide.	$\begin{array}{c} \text{C}_6\text{H}_4 \\ \text{CO} \end{array} \text{SO}_2 \text{NH}$	Imide group? Sulphur?

*C.—Bases.*

Methylene Blue (Medicinal).	Ghillany, Ehrlich, and Lippmann.	Tetramethylthionine.	$\text{C}_{19}\text{H}_{15}\text{N}_3\text{S}^+\text{Cl}^-$	Quinone group, sulphur.
Proctanin coeruleum crystallisatum.	Stillinz.	Crystal Violet.	$\begin{array}{c} (\text{CH}_3)_2\text{NC}_6\text{H}_4 \\ (\text{CH}_3)_2\text{NC}_6\text{H}_4 \end{array} \text{C}_6\text{H}_4\text{N} \begin{array}{c} \text{CH}_3 \\ \text{Cl} \\ \text{CH}_3 \end{array}$	Quinone group.
Ethylproctanin.	Stillinz.	Hexa-ethyl- <i>p</i> -rosaniline Hydrochloride.	$\begin{array}{c} (\text{C}_2\text{H}_5)_2\text{NC}_6\text{H}_4 \\ (\text{C}_2\text{H}_5)_2\text{NC}_6\text{H}_4 \end{array} \text{C}_6\text{H}_4\text{N} \begin{array}{c} \text{C}_2\text{H}_5 \\ \text{Cl} \\ \text{C}_2\text{H}_5 \end{array}$	Quinone group, six ethyls.
Proctanin aureum.	Stillinz.	Auramine.	$\begin{array}{c} (\text{CH}_3)_2\text{NC}_6\text{H}_4 \\ \text{NB}_2 \end{array} \text{C}_6\text{H}_4\text{N} \begin{array}{c} \text{CH}_3 \\ \text{Cl} \\ \text{CH}_3 \end{array}$	Quinone group.
Piperazine.	Scheering.	Diethylene diamine.	$\text{N} \begin{array}{c} \text{CH}_2 - \text{CH}_2 \\ \text{CH}_2 - \text{CH}_2 \end{array} \text{NH}$	—
Diuretin.	Gram and von Schroeder.	Theobromine sodium salicylate.	$\text{C}_7\text{H}_7\text{N}_4\text{O}_2\text{Na} + \text{C}_6\text{H}_5\text{OH} \cdot \text{COONa}$	Theobromine, salicylic acid.

*D.—Iodine Preparations.*

Iodol.	Carmichael and Silber.	Tetra-iodol pyrrol.	$\begin{array}{c} \text{Cl} = \text{Cl} \\   \quad   \\ \text{Cl} = \text{Cl} \end{array} \text{NH}$	Iodine.
Soluble with difficulty.	Ostermayer.	Di-iod- <i>p</i> -phenol potassium sulphate.	$\begin{array}{c} \text{Cl} = \text{CH} \\   \quad   \\ \text{HO.C} \quad \text{C.SO}_2\text{K} \\   \quad   \\ \text{Cl} = \text{CH} \end{array}$	Iodine?
Soluble easily.	"	Di-iod- <i>p</i> -phenol sodium sulphate.	$\begin{array}{c} \text{Cl} = \text{CH} \\   \quad   \\ \text{HO.C} \quad \text{C.SO}_3\text{Na} + 2\text{H}_2\text{O} \\   \quad   \\ \text{Cl} = \text{CH} \end{array}$	Phenol hydroxyl.
Aristol.	Messinger and Vertmann.	Dithymoldi-iodol.	$\begin{array}{c} \text{CH}_3 \\   \\ \text{IO} \\   \\ \text{C}_6\text{H}_5 \end{array} \text{C}_6\text{H}_2 - \text{C}_6\text{H}_2 \begin{array}{c} \text{CH}_3 \\   \\ \text{OI} \\   \\ \text{C}_6\text{H}_5 \end{array}$	Iodine.
Rubidium Iodidum.	Erhmann.	Rubidium iodide.	Rb I.	Iodine, Rubidium.

*E.—Medicaments containing Heavy Metals.*

Hamel.	Kobert.	Reduced blood-colouring matter.	47.5 per cent. carbon, 12 per cent. nitrogen, and about 1 per cent. iron.	Iron.
Hydrazgrum amido-succinum.	v. Mering.	Mercury succinimide.	$\begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{C}_2\text{H}_5 \quad \text{N.H}_2.\text{N} \quad \begin{array}{c} \text{CO} \\ \diagdown \quad \diagup \\ \text{C}_2\text{H}_5 \end{array} \end{array}$	Mercury.
Dermatol.	Heinz and Liebrecht.	Basic bismuth gallate.	$\text{H}^+ \text{C}_6\text{H}_4\text{COO, Bi(OH)}_2$	Bismuth.

—W. S.

## PATENTS.

*Manufacture of a New Chemical Substance from Orris-root.* J. C. W. F. Tiemann, Berlin. Eng. Pat. 8735, May 1, 1893.

In the alcoholic extract of orris-root the inventor has discovered a new substance, which is the aromatic principle of the root, and to which he gives the name "*irone*." It is a ketone, having the formula  $\text{C}_{15}\text{H}_{10}\text{O}$ . This body has the characteristic odour and flavour of the orris-root, and may be preferentially employed in perfumery, &c. Its preparation is carried out thus:—The alcoholic or ethereal extract of the root is distilled in a current of steam. Organic acids, ethers, alcohols, and irone pass over into the distillate, which is then treated with ether and the ethereal solution agitated with a dilute alkali solution in order to separate the free acids. The mixture is evaporated down and the residue dissolved in alcohol, which solution is mixed at the ordinary temperature with a weak solution of an alkaline hydrate in order to saponify the ethers of the organic acids. After some minutes it is poured into water, the neutral oils are dissolved in ether, the ether is evaporated, and the residue distilled in a current of steam. Irone is one of the bodies distilling over first, and by repeating this operation several times it may be obtained fairly pure, but still containing small quantities of aldehydes, which are eliminated by treatment with weak oxidising agents. The irone is then converted into its phenylhydrazone or condensed with another substituted ammonia to a ketone, from which bodies it is obtained by decomposing with dilute acids and distilling.

Irone boils at 111° C. under a pressure of 16 mm. and has a specific gravity of 0.939.—J. G. W.

*The Manufacture or Production of New Sulpho-Acids and Derivatives thereof.* H. E. Newton, London. From the Farbenfabriken vormals F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 9895, May 17, 1893.

DRIED gallic acid, or its alkaline salts, is gradually stirred into either sulphuric acid mono-hydrate, fuming sulphuric acid, or sulphuric chlorhydrin, taking care that the temperature does not rise too high. The product is cooled, when sulpho-gallic acid crystallises out. The salts of this acid

are obtained by saturating it with the hydroxides or carbonates of the metals or by acting on certain of its salts with metallic salts. The bismuth salt obtained by either of these methods is a yellow, apparently amorphous powder, having the following formula:—

Sulpho-gallic acid and its bismuth salt are more powerful antiseptics than gallic acid and its bismuth salt. Bismuth gallo-sulphonate is also less readily soluble in alkalis than bismuth gallate, and at the same time produces no stimulating effect on wounds, so that it possesses advantages as an antiseptic over that salt.—J. G. W.

*Process for obtaining Para-phenetolcarbamide ("Dulcin").* J. Wetter, London. From J. D. Riedel, Berlin. Eng. Pat. 10,850, June 2, 1893.

THE methods hitherto known for the production of *p*-phenetol-carbamide ("Dulcin") do not yield the theoretical amount owing to secondary reactions. The inventors claim that the theoretical yield is obtained by heating *p*-phenetidine to the boiling-point for several hours with an excess of an aqueous solution of urea nitrate, in a flask provided with an inverted condenser. An alternative process consists in heating *p*-phenetidine hydrochloride and free urea to 120° C. in an open vessel.—J. G. W.

*A New or Improved Anti-pyretic and Anti-neuralgic Preparation.* S. Radlauer, Berlin. Eng. Pat. 3179, Feb. 14, 1894.

WHEN acetanilide and salicylic acid are heated together in molecular proportions to a temperature of 100° C., an oily additive product is formed, which on further heating to 120° C. evolves acetic acid, leaving a body having the formula  $\text{C}_9\text{H}_9\text{N}.\text{CO}.\text{C}_6\text{H}_4.\text{OH}$  which is the subject of the patent. It melts at 100° C., is soluble in alcohol, but not so in water.

—J. G. W.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

## PATENT.

*An Improved Finely Granulated Paper, and Process for Producing the Same.* W. P. Thompson, Liverpool. From C. Schäuffelen, Heilbronn, Germany. Eng. Pat. 23,502, December 6, 1893.

IN patent 14,756, 1891, the inventor described the production of a granulated paper with a uniform grain of pyramidal form in relief. He now claims the production of a pyramidal granulated paper with recessed or depressed grains characterised by the grains, which are placed at a uniform distance apart, being depressed (*in intaglio*) instead of being raised or in relief, but which are produced in an exactly similar manner to the raised grains by one of the two calender rollers between which the paper passes, namely, the steel roller, having pyramidal or truncated cone shaped projections, instead of recesses on its surface. According to the fineness of the grain, there are 750, 1,000, 1,500, 2,500, &c. grains per square centimeter. The granulated paper is eminently suitable for photographic and lithographic purposes, and especially for all processes necessitating the use of a transfer plate.—E. G. P. T.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## PATENT.

*Improved Manufacture of Explosives from Nitrate of Ammonia and Resins.* C. D. Abel, London. From L. König, Berlin. Eng. Pat. 3024, February 12, 1894.

AMMONIUM nitrate and resin are powdered finely, separately or together, are well mixed, and then heated, preferably in a

closed apparatus, until the resin begins to melt. The mixture thus prepared, contains the particles of the salt partially, but not completely coated by resin, so that while on the one hand, no mechanical shaking devices will separate the constituents of the mixture, on the other hand, when ignited, as by a detonator, the combustion extends more rapidly than it would do if the particles of the salt were completely coated with the resin.—E. S.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPARATUS, ETC.

*A Viscosimeter for Lubricating Oils.* A. Kinkler. Dingl. Polyt. Journ. 290, 281—283.

IN the examination of lubricating oils, consisting of a mixture of fatty and mineral oils, at least the mineral oil should be tested by means of a viscosimeter. The quantities required for this test being necessarily somewhat large when the existing viscosimeters are used, the author has constructed a new apparatus requiring only 30 cc. The employment of a capillary tube as delivery tube (outflow) is claimed as a further advantage, the oil flowing through it under varying pressures, at different temperatures, whereas, in the case of the old viscosimeters, the determinations being made under the same conditions at different temperatures, inaccuracies arose, in consequence of the times of outflow being necessarily very short. In fact, to arrive at correct results, it would be necessary to employ delivery tubes of different size for higher or lower temperatures.

The new apparatus consists of a sheet brass (oil or water bath *w*, provided with a copper bottom, the contents of which may be heated by a gas lamp, the temperature of the heating liquid being read off by a thermometer held by *a*, *w*

contains the removable stand *d* placed firmly on four legs and supported by two brackets *h*. In this stand fits the viscosimeter, made of strong glass, and consisting of the neck or filling-tube *k*, through which also the thermometer passes, the bulb *c* bearing the mark *f*, the capillary tube *e*, the lower bulb *a*, and the ascending tube *b*; the whole apparatus is held in position by the spring-clamp *i*. The temperature of the contents of the viscosimeter is controlled by thermometer at *k*. The ascending tube *b* is supported by *l*; it is fitted with a tap *m*, and connected by means of india-rubber tubing with the suction apparatus *r*, in which the mercury used for aspirating the oil is allowed to rise up to the mark *p*. Bulb *t* serves as a receptacle for the mercury; can *y* is used for warming the oil to be tested to the desired temperature.

The apparatus must be gauged with a dilute glycerol solution of 1.110 sp. gr. at 20° C., and the time required for its outflow at 20° C. is taken as unity. For temperatures up to 100°, mercury is used as aspirating liquid, for higher temperatures water is preferred. For the heating vessel *w*

water is used for temperatures up to 100°, and above 100° an oil of high boiling point.

The test is carried out in the following manner. Fill *r* up to *p* with the aspirating liquid and heat the bath. In the meantime warm the oil to be tested in can *y* a few degrees above the required temperature. Take the viscosimeter for a short time—say half a minute—out of the bath, so that the air in *a* may be cooled a little; put it back, filling at the same vessel *e* with the oil up to mark *f*. The air in *a* will then expand so that no oil can enter it. Allow the oil in *e* to assume the temperature of the bath, connect the viscosimeter with the aspirator, and open tap *o*. Then open tap *m* and observe accurately the time required by the oil to rise in the ascending tube *b* up to the mark *g*.

For the accurate dimensions of the various parts of the apparatus (which may be had from C. Desaga, of Heidelberg) the original paper must be consulted.

The following table contains a few viscosimetric constants as determined with the new apparatus, contrasted with the numbers obtained by means of Engler's viscosimeter:—

Kind of Oil.	Kunkler's Viscosimeter.						Engler's Viscosimeter.					
	Seconds at			Glycerol Solution.			Seconds at			Water at 20° C.		
	29° C.	59° C.	100° C.	Sp. Gr. 1.110 at 20° C.	50° C.	150° C.	20° C.	50° C.	150° C.	(54 Seconds) = 1.	20° C.	50° C.

#### Apparatus for the Rapid Determination of Combustible Gases. G. G. Pond. Ber. 27, 692—696.

This apparatus, invented by Thomas Shaw, of Philadelphia, chiefly consists of two pumps, A and B (see figure); the

larger pump A constantly pumps the same volume, being fixed in position, as also is the length of the beam working the pump rod; the smaller pump B, on the other hand, is movable and the pump rod can be so arranged by means of

a scale along the beam as to deliver any required fraction of the maximum. A pumps air, or a mixture of air and combustible gas, whilst B pumps combustible gas only, viz., hydrogen, methane, illuminating gas, &c. Any required mixture of air and combustible gas can accordingly be made as required by pumping air by means of A, and the requisite proportion of combustible gas by means of B. In order to use the arrangement the sample of air or other mixture of gases containing inflammable gas (contained in an india-rubber bag) is first of all tested by pumping, together with air, into the testing cylinder C, and applying a light; if the explosion produced is violent a smaller quantity of the gas to be tested is employed relatively to the air, the mixture being pumped into the explosion cylinder D, and fired by a flame; if the explosion then produced is not too weak, the concussion projects a striker on to a bell, so as to ring a signal audibly. A series of trials is then made with gradually decreasing quantities of combustible gas until the limit is reached, when the violence of the explosion is not sufficient to ring the bell. For samples containing only small quantities of combustible gas, a series of observations is made with coal-gas (or hydrogen, &c.) and air, until a corresponding limit is arrived at, e.g., 8.0 per cent. of combustible gas; another series is then made with the air containing combustible gas to be tested and the same coal-gas (or hydrogen, &c.); if in this case the limit found is 5.3 per cent. of coal-gas, &c., it results that the quantity of combustible gas in the air tested is practically equivalent to  $8.0 - 5.3 = 2.7$  per cent. of the coal-gas, &c. used.—C. R. A. W.

## PATENTS.

*Improvements relating to the Sealing of Wires in Glass.*  
H. H. Lake, London. From J. B. Tibbatts, New York.  
U.S.A. Eng. Pat. 2048, January 30, 1903.

The method consists in using an annular collar made in the form of a dice-box, surrounding the wire to be sealed into glass at the point where the sealing-in is effected. The collar is of platinum or other suitable metal, and is soldered to the wire to be sealed in, and is in its turn fused into the glass by its edges, the waist being left free so that alteration of diameter of the wire by change of temperature can take place without straining the joint with the glass. The method is said to be adapted for the manufacture of incandescent lamps, and to be preferable to the plan of sealing in several small wires which is sometimes adopted when a large current has to be carried.—B. B.

INORGANIC CHEMISTRY.—  
QUANTITATIVE.

*Quantitative Analysis by Electrolysis.* O. Piloty.  
Ber. 27, 25, 280—282.

The author has made a number of electrolytic determinations of metals by Classen's method with the view of dispelling the doubt felt by many chemists as to their accuracy and applicability. He obtained good results in the precipitation of pure metals from their solutions, and the following figures in the separation of one metal from another or others:—

Separation.	Quantities taken and Precipitated.	Results per Cent.		Time of Electrolysis.
		Electrolytic.	Standard Method.	
Cu from Fe .....	1.0653 grms. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ + about 0.5 grm. of "an iron salt."	25.33	25.39	2½ hours.
Cu from Fe, Ni, Co ....	Copper sulphate (0.5—1 grm.) + about 0.5 grm. of "iron, nickel, and cobalt salts."	25.63 25.77	.. ..	3 hours.
Fe from Cr .....	Iron ammonium sulphate (0.5845) + about 0.5 grm. chrome alum.	14.27	14.28	4 hours.
Fe from Al .....	Iron-ammonium sulphate (0.861 grm.) + about 5 grm. alum.	14.53	.. ..	4 hours.
Ni from Cr .....	Nickel ammonium sulphate (0.684 grm.) + chrome alum.	15.44	15.15	4 hours.
Pb from Cu .....	Lead nitrate (0.6—0.7 grm.) + copper sulphate .....	72.42—72.7	72.24	5 hours.
Sb from Sn .....	Antimony trisulphide (0.3—0.6 grm.) + about 0.5 of "tin salt."	72.6—72.85	.. ..	Left overnight.
Sb from As .....	Antimony trisulphide (about 0.8 grms.) + about 0.5 grm. sodium arsenate.	72.69 72.86	.. ..	Left overnight.

—B. B.

*The Volumetric Estimation of the Bases in certain Metallic Salts.* F. H. English, Chem. Trade J. 14, 1894, 258.

WHEN titrating soluble metallic salts capable of being precipitated as carbonates with sodium or potassium carbonates, using phenolphthalein as indicator, the characteristic red coloration does not appear until all the bases are completely precipitated. From the foregoing it will be seen that certain bases belonging to the first five groups may be estimated by means of a solution of sodium carbonate. The method of analysis is as follows:—Solutions required (1) seminormal sodium carbonate, and (2) an alcoholic solution of phenolphthalein. From 1 to 2 grms. of the salt are dissolved in water and allowed to boil, and then titrated while still hot with the soda solution, using the phenolphthalein as indicator. The solution should be stirred briskly during the titration. With a little practice the final reaction can be easily detected.

In the case of oxides and carbonates or salts insoluble in water, but soluble in HCl, the method of analysis has to be slightly varied. The substance is weighed into a beaker and dissolved in the slightest excess of HCl. When completely dissolved the excess of acid is neutralised by Na,  $\text{CO}_3$  solution, using as indicator a solution of methyl

orange. When neutral, add phenolphthalein and a little water, boil, and proceed as before. The results obtained by the above method compare favourably with other well-known methods as regards accuracy and speed. The following analyses are the mean of several determinations, and show the suitability of the test for technical work:—

Base sought.	Salt taken.	Soda Method.	Gravimetric Method.
PbO .....	$\text{Pb}(\text{NO}_3)_2$ .....	67.17	67.13
$\text{Al}_2\text{O}_3$ .....	$^*\text{Al}_2(\text{SO}_4)_3 \cdot 15\text{H}_2\text{O}$ .....	17.99	17.98
ZnO .....	$\text{ZnSO}_4 + 7\text{H}_2\text{O}$ .....	28.38	28.38
CaO .....	$\text{CaCO}_3$ .....	55.86	55.88
BaO .....	$\text{BaCl}_2 + 2\text{H}_2\text{O}$ .....	62.50	62.50

\* Commercial salt.

This method is admirably adapted for the rapid estimation of lime in limestone and sifted lime, and is useful for those engaged in chemical works laboratories, where these

bodies have to be tested daily. It may also be of use to the practical dyeworks chemist for the estimation of aluminium in red liquors, and lead in lead nitrate liquors; of course, in estimating any individual base no other base capable of being precipitated as carbonate must be present. The method is not applicable in presence of ammonium compounds, which must be got rid of before applying the test.

*Estimation of Calcium Sulphide in Animal Charcoal by Means of Bromine.* P. Herrmann. *Die Deutsche Zuckerei* 1893, 18, 225.

25 grams of the finely-powdered charcoal are moistened, in a 250 cc. flask, with water, 2 to 3 cc. bromine added, and then 100 cc. luke-warm water. The whole is well shaken and then digested on the water-bath for half an hour. 80 cc. of hydrochloric acid of sp. gr. 1.1 are then slowly added, care being taken that the bromine vapours are not dispersed during this operation, so that there may be no chance of escape of hydrogen sulphide. The excess of bromine is then driven off over a naked flame, the volume, after cooling, made up to 250 cc., and then filtered and the sulphuric acid estimated in 200 cc. of the filtrate. After subtracting the barium sulphate due to the calcium sulphate originally present in the charcoal, multiplication of the residual weight of barium sulphate by the factor 1.515 gives the percentage of calcium sulphide in the charcoal. This method is quite as accurate as the nitric acid or potassium chlorate methods.—L. T. T.

*Method for the Determination of Iron in Iron Ore.* Messrs. Mixer and Dubets. *Eng. and Mining J.* 1894, 342.

It is rather surprising that the method described below, although in general use in the Lake Superior region, should be so little known outside of it. The method may be named, in a descriptive sense, the "stannous chloride, hydrochloric acid, and permanganate" method, and the authors do not know to whom credit should be given for having first formulated it.

For ordinary work less than half a gram. of ore is weighed out, the particular weight and the strength of the permanganate solution being so adjusted that by using a 50-cc. burette the per cent. may be read directly, the value of 1 cc. being 2 per cent.

A carboy is filled with a solution containing 250 grms. of permanganate and connected directly with the burette by glass tubing.

For extremely accurate work a 100-cc. burette may be used, with a more dilute solution.

The ore weighed out is placed in a suitable beaker, and 2½ cc. of stannous chloride solution added. (This solution is made up as follows:—One pound of stannous chloride is dissolved in one pound of concentrated hydrochloric acid and water, and diluted to 2 litres.) Then 10 to 15 cc. of hydrochloric acid (1:1) are added, a watch glass put on the beaker, which is then placed on an iron plate, and the contents boiled until the ore is completely dissolved. This will generally require from one to five minutes, depending upon the character of the ore, and the proportion of stannous chloride used, it being most advantageous to have enough stannous chloride present to reduce nearly all the iron to the ferrous state, that is, so that the solution only has a light yellowish-green colour. The rapidity with which the ore dissolves, owing to the presence of the stannous chloride, is a great advantage in shortening the time required for the analysis, and is of considerable theoretical interest as to its exact cause.

When the ore is dissolved, and whilst still hot, additional drops of stannous chloride are cautiously added from a burette, until the yellow colour just disappears, the solution being constantly agitated by giving the beaker a slight rotating motion, thus doing away with the use of a glass rod. To the contents of the beaker are added about 5 cc. of a saturated solution of mercuric chloride, to take up the slight excess of stannous chloride, which reaction is shown by the formation of mercurous chloride, a white, silky

precipitate. The solution is now poured into the titrating beaker, of about 500 cc. capacity, diluted with water, and 5 to 10 cc. of the titrating solution added. The titrating solution is prepared by dissolving 160 grms. of manganese sulphate in water and diluting to 1,750 cc., to which are added 330 cc. of phosphoric acid and 320 cc. of sulphuric acid.

The solution is now ready for titrating, which is accomplished in the usual way. After the mercuric chloride has been added the titration must be performed immediately.

As is well known, the permanganate solution rarely varies, when protected from light and changes in temperature, by easing around the carboy.

Nevertheless, the authors always make sure of it by making one or two analyses of a standard ore with every set of determinations, which, being under precisely the same conditions, will immediately indicate any error in weight or solution; this precaution we consider very important, as it takes little extra work and insures the accuracy of the results.

Duplicates generally agree, and rarely differ more than one-tenth of one per cent. In a standard ore that was recently submitted to several chemists for analysis, the three chemists using this method reported 67.02 per cent., 67.02 per cent., and 67.08 per cent. as their respective results, and the average by all methods was 67.04 per cent.

There is claimed for this method greater rapidity of working and equal accuracy with any other method now employed in iron analysis of ores.

*Estimation of Chromium and Manganese in Steel.* L. Schneider. *Oester. Zeits. f. Berg- und Hüttenkunde*, 1892, 235.

The author's process is based upon the conversion of the lower oxides of these metals into the highest (acid) oxides by the action of lead peroxide in presence of nitric acid. The metal (2 grms.) is dissolved in dilute sulphuric acid (100 cc.), and after oxidising with nitric acid (5 cc.) lead peroxide (5 grms.) is added, and boiled with the solution for 15 minutes. The chromic and manganic acids resulting are estimated volumetrically in the usual way.—C. F. C.

*Colorimetric Estimation of Iron in Spring Waters.* F. Gerhard. *Archiv. der Pharm.*, 230, 705.

The author makes use of the well-known "tannin" reaction. The colour develops most satisfactorily and uniformly in presence of sodium pyrophosphate, which whilst giving the necessary slightly alkaline reaction forms a soluble double salt with ferric compounds. The standard solutions of the latter (0.0001 Fe per cc) is prepared by taking the necessary quantity of a ferric salt, dissolving together with 2.5 grms. sodium pyrophosphate and diluting to 1000 cc. The details of the estimations are of the usual order.—C. F. C.

*The Effect of Platinum in Iron Solutions.* R. W. Mahon. *Americ. Chem. J.* 1893, 15, 578—582.

The minute quantity of platinum which a platinum crucible, used for the fusion of insoluble iron ore residues with sodium carbonate, may lose, is imparted to the subsequent solution of the fusion in water and hydrochloric acid. These traces of platinum form, according to the author, a source of error, when the iron is estimated by titration with potassium bichromate, after reduction by stannous chloride, dilution, and addition of mercuric chloride in excess. Stannous chloride added to the hot hydrochloric acid solution of ferric and platonic chlorides is described as first reducing the iron, and then the platinum. The solution which becomes gradually colourless during the reduction of the iron, again assumes a yellow tinge, due to the trace of platinous chloride which is formed. Moreover, when mercuric chloride is added, as above described, the substance sometimes has a tinge of colour, whilst, when platinum is absent, a colourless solution with pure white mercurous chloride in suspension

occurs. The titration with potassium bichromate shows the usual reaction with potassium ferri-cyanide, but when platinum is present, a recurrent bluing after the completion of this colour reaction may be encountered. This recurrence is sometimes rapid enough to amount to a continuous coloration. Thus a small quantity of platinum may introduce a considerable error into the estimation.

To prevent this, the author recommends two methods:—Firstly, to add the stannous chloride with great care, and to cease when the colour due to the ferric compound has disappeared, and before the above-described yellow tinge due to platinous chloride has made its appearance. Secondly, to precipitate the iron in the fused and dissolved residue by means of ammonia, to collect the precipitate on a small filter, and after thorough washing to redissolve it in hydrochloric acid and hot water, whereby a solution is obtained which is entirely free from platinum. In cases where great accuracy is required this second method is preferable to the first.—H. S.

#### Quantitative Electrolytic Estimation of Lead.

A. Kreichgauer. Ber. 27, 315—318.

CHECK experiments on the electrolytic formation of lead dioxide from an acid solution of lead nitrate indicated that with a solution containing 1 part of nitric acid sp. gr. 1.14 and 5 to 7 of water, an excess of lead was indicated of a few tenths per cent., which was lessened by washing twice with alcohol to slightly below the theoretical amount. A current capable of furnishing 0.2 cc. of detonating gas per minute precipitated all lead from solution in 14 hours, but no error was noticed on prolonging the duration to upwards of 40 hours; no difference was observed whether the dioxide thrown down was weighed after drying at 110° or at 200°. A set of four Meidinger cells and the dish electrode arrangement recommended by Claisen were employed.

—C. R. A. W.

#### The Use of Lead Pipes for Conveying Water. M. T. Leeco. Chem. Zeit. 17, 1431—1432.

THE tests described in this paper were made upon the new water supply of the city of Belgrade (a full analysis of the water is given). This water contains iron, calcium, and magnesium salts, is of 24.8° total hardness (German scale), and holds in solution more than 0.5 gm. CO<sub>2</sub> per litre.

Lead was tested for, in water which had stood over night in the pipes, as follows:—One litre of water acidified with acetic acid was evaporated down to 100—200 cc., filtered, and a drop of dilute sulphuretted hydrogen water added. If lead is present, even in the most minute quantity, a darkened coloration of the water is observed. As this reaction might be partially obscured by the precipitation of the iron present in the water, it is necessary to make a test at the same time with a sample known to be free from lead.

An estimation of the amount of lead may be carried out with great accuracy in the following way:—One litre of the water is acidified with 5 cc. glacial acetic acid, concentrated to 100 cc., filtered, and one or two drops of dilute H<sub>2</sub>S water added (one part saturated H<sub>2</sub>S water with two parts distilled water). At the same time the sample known to be free from lead is treated in an exactly similar manner. If lead is detected in the first sample, add to the second such an amount of a solution containing 0.1 mg. lead in 1 cc. That the two solutions have exactly the same colour. The amount of lead added to the second sample is the amount present in the first. By this means 0.05 mg. lead per litre may be estimated.

In carrying out the tests here described a piece of lead pipe 7 metres in length, and 22 mm. in diameter was employed. The solvent effect of the water on the lead was greater at first than after the tube had been some time in use. But even after three months, about 0.3 mg. lead per litre was found in water which had stood 24 hours in the pipe. After three hours standing a trace of lead was detected, but in water which had merely run through the

pipe no lead could be found. Therefore, where lead pipes are used the water should be allowed to run for a few minutes before taking it for drinking purposes.

The somewhat large amounts of lead dissolved by this particular water may be due to its richness in free carbonic acid. The author recommends that subsequent papers on this subject should include a full analysis of the water, in addition to the method adopted for estimating lead. If this suggestion were fully carried out, it would be possible, with the help of medical men who would inform us as to the amount of lead rendering water unfit for drinking, to definitely solve the question of the suitability of lead pipes for conveying water.—R. B. B.

#### Quantitative Analysis by Electrolysis.—The Electrolytic Determination of Lead. A. Claisen. Ber. 27, 163—165.

AS Luckow has shown, the complete oxidation of lead to peroxide is, in the first place, dependent upon the presence of a certain amount of nitric acid. The quantity requisite, as was first proved in the electro-technical laboratory at Munich, must be regulated by the temperature of the solution and the density of the current used. It was found that the latter depended upon the nature of the anode; with an anode with a very smooth surface the current density must only be 0.05 ampère per 100 sq. cm., under other conditions, 0.5 ampère. Whilst observing all these conditions, the quantity of peroxide that can be precipitated in an adhering form is relatively small.

The rapid deposition of large amounts of lead peroxide can, however, be effected if the platinum dish used as anode is roughened on its inner surface by a sand-blast. By this means in a few hours as much as 4 grms. of peroxide per 100 sq. cm. of surface can be precipitated with a current of 1.5 ampères.

To make this estimation, after dissolving the lead salt, 20 cc. of nitric acid (sp. gr. 1.35—1.38) is added, the liquid is diluted to about 100 cc., then warmed to 50°—60° and electrolysed with a current of  $N.D_{100} = 1.5—1.7$  ampère. By continuing the warming during the electrolysis as much as 1.5 grms. of lead peroxide can be precipitated in three hours, and larger quantities in from four to five hours. To prove the complete separation of the lead, about 20 cc. of water are added, and it is observed whether or not there is any darkening of the freshly-wetted surface of the anode. If after 10—15 minutes, no darkening is visible, the precipitate is washed with water and alcohol, and dried at 180°—190°. A temperature of 110° to 130°, as prescribed by some other chemists, does not suffice. The intensity of the current does not influence the character of the precipitate; in the author's experiments it varied from 4 to 8 volts.

When copper and lead are to be estimated in the same solution, after adding 20 cc. of nitric acid, the volume of liquid is only made up to about 75 cc., and the warm solution is then electrolysed with a current of  $N.D_{100} = 1.5$  to 1.7 ampère; but at the end of an hour the operation is interrupted. By this time from 98—99 per cent. of the lead will have deposited upon the anode, but none of the copper will have deposited on the cathode. The liquid is now transferred to another tared dish, and the precipitated lead peroxide washed, dried, and weighed. The washings are added to the liquid in the second dish. To the solution containing the whole of the copper and the rest of the lead, ammonia is added until the blue colour of an ammoniacal copper solution is permanent, after which about 5 cc. of nitric acid are added, the solution is made up to 120—150 cc., and is then electrolysed with a current of  $N.D_{100} = 1$  to 1.2 ampère. In this electrolysis, however, the tared dish is made the cathode upon which the copper deposits, and the perforated platinum foil or "bucket-electrode" already described by the author (Handbuch der Elektrolyse, p. 56), is used as anode upon which the remainder of the lead peroxide in deposits. From three to four hours are required to separate about 0.25 grms. of copper and the rest of the lead.

When dealing with substances containing sulphur, the separation of lead sulphate frequently causes trouble owing to the difficulty of bringing it into solution in nitric acid.

When lead sulphate forms during solution of the substance to be analysed, ammonia must be added to the liquid in slight excess, and heat applied for a few minutes. This converts the dense lead sulphate into the bulkier lead hydrate. The liquid is then poured, little by little, into the platinum dish, into which about 20 cc. of nitric acid have previously been placed and warmed, whilst it is stirred continuously with the electrode. The lead sulphate that is thereupon formed now redissolves at once either the whole of it or the greater part, so that the remainder dissolves after warming for a short time. The vessel in which the treatment with ammonia was carried out is first rinsed out with a little nitric acid and then with water.

The above described modification can be applied to the separation of large quantities of manganese peroxide, and also to the precipitation of some metals, antimony for example, which hitherto could only be separated in minute quantities. The author intends to make further communications on his experiments on these and other allied points.—H. S. P.

*The Separation and Estimation of Metals in Alkaline Solution by means of Hydrogen Peroxide.* P. Jannasch and J. Lesinsky. Ber. 26, 2908—2912.

SEPARATION of bismuth from copper:—

(1.) *In the Cold.*—A mixture of 50 cc. of 3 per cent. hydrogen peroxide with 15 cc. of concentrated ammonia was gradually added to a solution of 0.3 gram. of each of the pure metals. The faintly yellow precipitate of bismuth hydroperoxide is washed first with a mixture of 2 vols. of hydrogen peroxide, 1 vol. of strong ammonia, and 8 vols. of water, then with warm diluted ammonia (1:8) and ultimately with hot water, care being taken to ensure the complete removal of the copper. After drying at  $90^{\circ}$ — $95^{\circ}$  the precipitate is ignited in a platinum crucible, redissolved in nitric acid and ignited a second time until the weight remains constant. The barium salts and silicic acid contained in commercial hydrogen peroxide are carried down with the bismuth precipitate, hence the results turn out too high and must, if absolute accuracy be desired, be corrected by subtracting the estimated amount of these impurities from the original weight of the bismuth oxide. The copper contained in the filtrate from the bismuth precipitate is, after expulsion of the ammonia, separated from the re-acidulated and diluted solution as sulphide, converted into oxide by ignition in a current of oxygen and weighed as such.

(2.) *With the Application of Heat.*—The solution to which the hydrogen peroxide mixture was added in the cold is heated from 5 to 10 minutes on the water-bath, filtered hot, and the precipitate washed as in (1), but with hot liquors exclusively. If no hydroxylamine be present in the solution the bismuth precipitate retains but extremely small traces of copper, in the presence of a more considerable quantity of hydroxylamine these traces become more noticeable, but may be completely removed by a second precipitation.

Compared with the usual method of separating bismuth from copper by means of ammonia or ammonium carbonate the separation of these metals by means of hydrogen peroxide presents the advantages of greater speed and accuracy.—F. M.

*The use of Ammoniacal Mercuric Cyanide in Quantitative Analysis.* F. W. Schmidt. Ber. 27, 225.

THE conversion of metallic sulphides, precipitated in the ordinary course of analysis, into some form capable of satisfactory weighing, involves either re-solution and precipitation as oxide or carbonate or treatment by Rose's method with sulphur in a stream of hydrogen to obtain an anhydrous sulphide. The process of ignition with mercuric oxide or with a mixture of that substance and mercuric nitrate is not invariably available as basic sulphates are sometimes formed, difficult of decomposition at the temperature of ignition. The conversion can, however, be effected by the use of ammoniacal mercuric cyanide, a cyanide of the metal to be determined being formed, whilst mercuric sulphide is produced in equivalent amount. The metallic cyanide is decomposed on heating in the air, the

mercuric sulphide volatilises, and an oxide of the metals remains. No formation of mercuric sulphocyanide occurs and thus the removal of mellone (a fairly fixed substance) is avoided. Similarly para cyanogen from the decomposition by heat of the excess of mercuric cyanide is not obtained when an ammoniacal solution of the cyanide is used, and thus the difficulty of volatilising so fixed a body, does not arise. This difference in the behaviour of mercuric cyanide and the same salt in ammoniacal solution is due to the formation of the body  $\text{Hg}(\text{CN})_2\cdot\text{NH}_3$ , which the author has prepared and examined. It can be obtained by saturating a strong solution of ammonia with mercuric cyanide, at a gentle heat on the water-bath, and strongly cooling the solution. Crystals several centimetres in length separate, and can be dried in an atmosphere of ammonia; on exposure to air they lose ammonia, and rapidly decompose.  $\text{Hg}(\text{CN})_2\cdot\text{NH}_3$  is with difficulty soluble in water, its aqueous solution is immediately precipitated by  $\text{H}_2\text{S}$ , but when previously made acid with hydrochloric acid, it gives with  $\text{H}_2\text{S}$  at first a yellow, and then a white, precipitate, the latter becoming black on dilution.

The general method of using ammoniacal mercuric cyanide for converting metallic sulphides into oxides, consists in placing the moist precipitate together with the filter in a crucible, covering it with a solution of the reagent, evaporating to dryness, then heating first gently with a Bunsen flame, then strongly, if necessary, over the blow-pipe. In the case of copper and zinc, this treatment suffices and no further description is necessary, but with bismuth, reduction of a portion to metal takes place and must be corrected by subsequent evaporation with nitric acid and ignition of the nitrate to oxide. The conversion of ferrous sulphide to ferric oxide is also certain and complete. A similar result is to be expected for nickel and cobalt.

—B. B.

ORGANIC CHEMISTRY.—QUALITATIVE.

*The Detection of "Abrastol," Calcium  $\beta$ -naphthol Sulphonate in Wines.* Sinibaldi. Monit. Scient. 7, 842.

ABRASTOL forms a pinkish-white powder, of which 100 parts of water or alcohol dissolve respectively 167 and 50 parts at  $15^{\circ}\text{C}$ . Its most characteristic reaction is the slatey-blue coloration it yields with ferric chloride. This coloration changes to green on warming. Abrastol when heated with hydrochloric acid, is converted into naphthol, sulphuric acid, and calcium sulphate. The detection of abrastol in wine may be effected as follows:—25 cc. of wine are neutralised by the addition of a few drops of ammonia, and shaken with 25 cc. of pure amyl alcohol. After separation the amyl alcohol is boiled to expel any traces of ammonia, and after cooling is agitated with  $\frac{1}{4}$  cc. of ferric chloride solution. In presence of abrastol the amyl alcohol assumes the slatey-blue coloration already mentioned. In the case of wines containing but little abrastol, 250 cc. should be evaporated at a low temperature (in vacuo, if possible), the residue extracted by 30 cc. of absolute alcohol, and the alcoholic extract evaporated to dryness. The residue is dissolved in water and treated with amyl alcohol as above (see page 534).—H. T. P.

ORGANIC CHEMISTRY.—QUANTITATIVE.

*A New Method of Estimating Naphthol- and Naphthylamine Sulphonic Acids.* W. Vaubel. Chem. Zeit. 1893, 1265 and 1897.

THE property of these sulphonic acids of combining with one or more molecules of bromine is utilised for their volumetric estimation. The *modus operandi* consists in adding a standard solution of potassium bromate to a mixture of an aqueous solution of the sulphonic acid with potassium bromide and sulphuric acid until the liquor permanently shows the presence of free bromine. The acids, according to their capacity of taking up bromine, may be classed as follows:—

1. Sulphonic acids, which at the ordinary temperatures, generally take up only one atom of bromine, and in case of

which the completion of the reaction is easily recognised. This group includes—

	NH <sub>2</sub>	SO <sub>2</sub> H	SO <sub>3</sub> H
<b>A. of α- and β-naphthylamine sulphonic acids:</b>

(f.) β-naphthylamine-δ-monosulphonic acid I (3Br).	2	7	..
<b>B. α-naphtholmonosulphonic acid S</b>			
	OH 1	8	..

III. Sulphonic acids combining with bromine only at high temperatures. The following take up one bromine atom at 65°—70°.

	NH <sub>2</sub>	SO <sub>2</sub> H	SO <sub>3</sub> H
β-naphthylamine-α-monosulphonic acid	2	8	..
Amido-G-acid	2	6	8
<b>OH</b>			
Croceine sulphonic acid	2	8	..
G-acid	2	6	8

The combination of the bromine method with the well-known method based upon the formation of diazo-com-

pounds in many cases furnishes a means of estimating separately the sulphonic acids contained in a mixture.

## New Books.

**PRACTICAL PAPER-MAKING.** A Manual for Paper Makers and Owners and Managers of Paper Mills, to which are appended useful Tables, Calculations, Data, &c. By GEORGE CHAMBERLAIN. London: Crosby, Lockwood, and Son, 7, Stationers' Hall Court, Ludgate Hill. 1894. Price 5s.

8vo. volume, bound in cloth, and containing 198 pages of subject-matter, exclusive of preface, table of contents, and alphabetical index. There is also a frontispiece containing two figures representing the microscopic structure of cotton, manilla, and hemp. The text is illustrated with 16 microphotographs representing the appearances of cellulose fibres and their mineral adulterants, or "filling" agents. The Appendix supplies various data of value and interest to manufacturers. For example, we have the "Equivalent Weights and Sizes of Writing Papers," "Sizes of Book and Drawing Papers," "Various Calculations relating to Weight of Reams and Webs," &c., &c.

The following subjects are treated of in the work:—I. Chemical and Physical Characteristics of Various Fibres. II. Cutting and Boiling of Rags. Jute Boiling and Bleaching. III. Wet Picking, Washing, Breaking, and Bleaching. Electrolytic Bleaching. Antichlor. IV. Cellulose from Wood. Mechanical Wood Pulp. V. Esparto and Straw. VI. Beating. VII. Loading. Starch. Colouring Matter. VIII. Resin, Size, and Sizing. IX. The Fourdrinier Machine and its Management. X. Animal Sizing. Drying. XI. Glazing and Burnishing. XII. Cutting. Finishing. XIII. Microscopical Examination of Paper. XIV. Tests for Ingredients of Paper. XV. Recovery of Soda. XVI. Testing of Chemicals. Testing Water for Impurities.

**LAW AND THEORY IN CHEMISTRY.** A Companion Book for Students. By DOUGLAS CARNEGIE, M.A. London: Longmans, Green, and Co. New York: 15, East 16th Street. 1894. Price 6s.

This book is stated to contain the substance of a course of eight lectures delivered before an audience of school teachers of Elementary Chemistry at Colorado College, U.S.A. The character of the work may be summed up as the history of the development of modern chemical theory, and the subject is subdivided as follows:—I. Alchemy and the Birth of Scientific Chemistry. II. The Phlogistic Period and the Beginnings of Chemical Theory. III. Chemical Classification. Mixtures. Compounds. Elements. IV. The Atomic Theory. V. The Classification of Compounds, Acids, Bases, Salts. VI. Isomerism and Molecular Architecture. VII. Chemical Equilibrium. The text occupies 222 pages, the book is of 8vo. size, and is strongly bound in cloth.

**ENGINEERING CHEMISTRY.** A Practical Treatise for the Use of Analytical Chemists, Engineers, Ironmasters, Ironfounders, Students, and others. Comprising Methods of Analysis and Valuation of the Principal Materials used in Engineering work with numerous Analyses, Examples, and Suggestions. By H. JOSHUA PHILLIPS, F.I.C., F.C.S. Second Edition, Revised and Enlarged. London: Crosby, Lockwood, and Son, 7, Stationers' Hall Court, Ludgate Hill. 1894. Price 10s. 6d.

This is a book the object of which is mainly to give precise methods for analysing and valuing the most important of

the materials in general use by engineers. The author having long entertained the idea of writing such a volume, and having been continuously engaged in the laboratories of railway companies, has gradually collected together the materials for it. This volume, which is strongly bound in cloth, forms an 8vo. containing 388 pages of subject matter, to which is added an alphabetical index. In the text are to be found some 50 woodcuts, and numerous tables. The sub-division of the text into chapters under the primary subjects or themes of which they treat, will give most concisely the plan of the work and its detailed method of arrangement. **EXCEPTION:** Reddrop's System of Reagents. I. Metals, Alloys, &c. II. Ores, Limestones, &c. III. Fuels.—Solid, Liquid, and Gaseous. IV. Water. V. Oils. VI. Materials used in Grease Making. VII. Gasworks Products. VIII. Disinfectants. IX. Explosives. Appendix, with a variety of tabular matter.

**THE TANNINS.** A Monograph on the History, Preparation, Properties, Methods of Estimation, and Uses of the Vegetable Astringents, with an Index to the Literature of the Subject. Vol. II. By HENRY TRIMBLE, PH.D., Professor of Analytical Chemistry in the Philadelphia College of Pharmacy, Philadelphia, U.S.A. J. B. Lippincott Company. 1891.

THIS second volume by Prof. Henry Trimble on the Tannins, is devoted to the results of investigation by him on the astringent principles from nine species of oaks and one species each of mangrove, canaigre, and chestnut.

Oak barks have been collected and examined from three different quarters of the globe, so that conclusions regarding the oak tannins are not based on too narrow foundations.

A valuable index to the literature of the tannins is given and occupies some 30 pages, the total text filling 170 pages. The work concludes with an alphabetical index of subject matter and another of authors. It is an 8vo. volume and bound in cloth.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

#### NEW CUSTOMS TARIFF OF BRITISH INDIA.

A copy of the Indian Tariff Act of 1894, which received the assent of the Governor-General on the 10th March last, has been received at the Board of Trade from the India Office. The following is a statement of some of the rates of import duties now levied under this Act:—

#### Import Tariff.

No.	Names of Articles.	Tariff Valuation.	Duty.
<i>Chemicals, Drugs, Medicines, and Narcotics, and Dyeing and Tanning Materials.</i>			
7	Chemical products and preparations:	Rs. a.	
	Acid, sulphuric .....	Lb. 0 2	5 per cent.
	Alkali, country (sajji-khâr) Cwt.	2 0	"
	Alum .....	" 5 0	"
	Arsenic .....	" 25 0	"
	Do., China mansil .....	" 16 0	"
	Bicarbonate of soda .....	" 7 0	"

#### Import Tariff—continued.

No.	Names of Articles.	Tariff Valuation.	Duty.
	Chemical products, &c.— <i>cont.</i>	Rs. a.	
	Copperas, green .....	Cwt. 3 0	5 per cent.
	Explosives, namely, blasting gelatin, dynamite, roborite, tonite, and all other descriptions, Sal ammoniac .....	Cwt. 30 0	"
	Sulphur (brimstone), flour ..	" 5 8	"
	Do., do., roll .....	" 5 0	"
	Do., do., rough .....	" 4 0	"
	All other sorts of chemical products and preparations.	<i>ad val.</i>	"
8	Drugs, medicines, and narcotics:		
	Aloes, black .....	Cwt. 14 0	"
	Do., Socotra .....	" 25 0	"
	Aloe wood .....	Lb. 3 0	"
	Asafoetida (hing) .....	Cwt. 80 0	"
	Do., coarse (hingra) .....	" 18 0	"
	Atary, Persian .....	" 15 0	"
	Brimstone (amalsara) ..	" 45 0	"
	Camphor, Bhemasani (baras) ..	Lb. 100 0	"
	Do., refined, cake .....	" 1 0	"
	Do., crude, in powder ..	" 0 12	"
	Cassia lignea .....	Cwt. 20 0	"
	China root (chobchini), rough ..	" 7 0	"
	Do., do., scraped .....	" 16 0	"
	Galangal, China .....	" 8 0	"
	Pellitory (takalkara) .....	" 30 0	"
	Salep .....	" 100 0	"
	Senna leaves .....	" 4 8	"
	Storax, liquid (rose mel-foet) ..	" 46 0	"
	Tobacco, manufactured and un-manufactured.	<i>ad val.</i>	"
	All other sorts of drugs, medicines, and narcotics, except quinine, which is free, and opium (for which see Schedule of liquors, opium, salt, and salted fish).	"	"
9	Dyeing and tanning materials:		
	Aizarin dyes, all colours .....	"	"
	Aniline, do., do. ....	Lb. 1 8	"
	Cochineal .....	" 1 0	"
	Gallnuts, myrabolans ..	Cwt. 4 8	"
	Do., Persian .....	" 37 0	"
	Madder or manjit .....	" 12 0	"
	Orchilla weed .....	" 9 8	"
	Sappan wood and root ..	" 5 8	"
	All other sorts of dyeing and tanning materials.	<i>ad val.</i>	"
<i>Oils.</i>			
	Cassia .....	Lb. 3 0	"
	Cocunut .....	Cwt. 13 0	"
	Grass .....	Lb. 1 12	"
	Junjili or til .....	Cwt. 15 0	"
	Linseed, European .....	Imp. gall. 1 12	"
	Oil, of sorts .....	Ounce 10 0	"

## Import Tariff—continued.

No.	Names of Articles.	Tariff Valuation.	Duty.
	Petroleum, including also naphtha and the liquids commonly known by the names of rock-oil, Ranceon oil, Borina oil, kerosene, paraffin oil, mineral oil, petrolene, gasoline, benzol, benzoline, benzine, and any inflammable liquid which is made from petroleum, coal, schist, shale, peat, or any other bituminous substance, or from any products of petroleum.	Rs. 36.	1 anna per imp. gall.
	Do., which has its flashing point at or above 200° of Fahrenheit's thermometer, and is proved to the satisfaction of the Customs collector to be intended for use exclusively for the latching of jute or other fibre or for lubricating purposes.	<i>ad val.</i>	5 per cent.
	Sandalwood..... Lb.	8 0	"
	Turpentine..... Imp. gall.	1 14	"
	Whale (except spermaceti) Cwt.	15 0	"
	Wood..... "	25 0	"
	All other sorts of oil.....	<i>ad val.</i>	"
<i>Other Articles. Unmanufactured and Manufactured.</i>			
7	Candles, paraffin..... Lb.	0 5	"
	Do., spermaceti..... "	0 6	"
	Do., wax..... "	1 0	"
	Do., all other sorts, including composition..... "	0 5	"
31	Gums, gum-resins, and articles made of gum or gum resin:		
	Copal..... Cwt.	55 0	"
	Cuteh and gambier..... "	17 0	"
	Gum ammoniac..... "	14 0	"
	Do., arabic..... "	18 0	"
	Do., Bellium (common gum)..... "	10 0	"
	Do., Benjamin..... "	40 0	"
	Do., Bysibol (coarse myrrh)..... "	14 0	"
	Do., Oilinum or frankincense..... "	12 0	"
	Do., Persian (false)..... "	10 0	"
	Do., Kino..... "	10 0	"
	Myrrh..... "	30 0	"
	Rosin..... "	1 4	"
	All other sorts of gums, gum-resins, and articles made of gum or gum resin.....	<i>ad val.</i>	"
39	Leather, and articles made of leather, including boots and shoes, harness and saddlery, but excluding belting for driving machinery, which is free.	"	"
41	Matches, lucifer, and all other sorts.....	<i>ad val.</i>	"
43	Oilcloth and floorecloth.....	"	"
44	Paints, colours, painters' materials, and compositions for application to leather and metals:		
	Ochre, other than European, all colours..... Cwt.	1 5	"
	Paints of sorts..... "	9 0	"
	Do., composition..... "	55 0	"
	Do., patent driers..... "	10 0	"
	Prussian blue, China..... Lb.	0 10	"
	Do., European..... "	1 0	"

## Import Tariff—continued.

No.	Names of Articles.	Tariff Valuation.	Duty.
	Beets, colours, &c. ....	Rs. 36.	5 per cent.
	Red-flower..... Cwt.	12 0	"
	Turpentine..... Imp. gall.	1 14	"
	Verdigris..... Cwt.	70 0	"
	Vermillion, Canton..... { Box of }	94 0	"
	White lead..... Cwt.	14 0	"
	All other sorts.....	<i>ad val.</i>	"
45	Paper of all kinds.....	"	"
46	Perfumery:		
	Rose flowers dried..... Cwt.	12 0	"
	Rosewater..... Imp. gall.	1 14	"
	All other sorts, except perfumed spirit (for which see Schedule of liquors, opium, salt, and salted fish).....	<i>ad val.</i>	"
49	Pitch, tar, and dammer:		
	Bitumen.....	"	"
	Dammer..... Cwt.	6 0	"
	Pitch, American and European.....	6 0	"
	Do., coal.....	2 8	"
	Tar, American and European.....	6 0	"
	Do., coal.....	2 8	"
	Do., mineral.....	<i>ad val.</i>	"
53	Soap.....	"	"
54	Stationery, excluding paper (for which see No. 45).....	"	"
55	Stone and marble.....	"	"
56	Tallow and grease..... Cwt.	25 0	"

## THE NEW RUSSO-GERMAN COMMERCIAL TREATY.

We give below the principal pharmaceutical articles on which Russia has agreed to lower the Customs duty in the new commercial treaty with Germany. In cases where these rates are lower than those hitherto levied upon imports from countries with which Russia trades on the "most-favoured-nation" basis, those countries (of which the United Kingdom is one) participate in the benefit. The rates are given in roubles per pound, the figures in ( ) denoting the rates at present levied under the "war" tariff:—

Salts of chromic acid soluble in water—*e.g.*, bichromate of potash, neutral chromate of potash, chromate of soda, 2·15 (2·65); tannic acid (taunin) 5·00 (6·00); blue copperas, except anhydrous copperas, Salzburg copperas (a mixture of sulphates of iron and copper), white copperas or sulphate of zinc, chloride of zinc, 0·80 (1·00); tartar emetic, 3·00 (4·00); chemical and pharmaceutical products not specially tariffed, gross weight, 1·50 (gross weight, 1·80); proprietary medicines the importation of which is authorised in accordance with the special list, gross weight, 16·00 (gross weight, 16·00); precipitated or washed chalk, chalk and tale ground, gross weight, 0·12 (gross weight, 0·15); white-lead and zinc-white, 0·50 (0·60); red-lead, 0·35 (0·40); colours with base of copper (except verdigris, or of arsenic), 3·00 (4·00); verdigris (basic acetate of copper), 3·60 (4·00); dyeing substances (pigments) prepared with products from the distillation of coal-tar; alizarine, extract of madder, lac of madder or alizarine; cochineal carmine, carmine lac; indigotine (indigo extract in a dry state), 14·00 (17·00). Colouring substances mixed with non-colouring materials, such as clay and oil, pay duty at the rate of 3r. per pound when the colouring substance does not exceed 10 per cent. of the total weight of the mixture.—*Chemist and Druggist.*

### SOME OF THE CONTEMPLATED CHANGES IN THE UNITED STATES TARIFF.

April 27th, 1894.

## STATISTICS.

## MINERAL PRODUCTION OF THE UNITED KINGDOM.

The official returns of mineral production in Great Britain and Ireland in 1893 have just been made public, and we give below a table showing the output for the year, compared with that for 1892 and 1891. The statistics covering a long series of years will be found in the new volume of the "Mineral Industry." The figures given below are in long tons (2,240 lb.) :—

*Mineral Production of the United Kingdom.*

Description of Mineral.	1891.	1892.	1893.
	Tons.	Tons.	Tons.
Alum clay (banxite).....	10,763	7,322	8,740
Arsenic.....	6,049	5,114	5,976
Arsenical pyrites .....	5,995	4,497	3,036
Barytes.....	26,876	21,217	22,343
Clays (excepting ordinary clay).....	827,970	891,519	878,965
Coal.....	185,479,126	181,786,871	164,325,795
Copper ore.....	8,836	5,995	5,346
Copper precipitate .....	322	270	230
Fireclay.....	2,334,065	2,212,333	2,186,243
Fluorspar.....	141	171	215
Gold ore .....	14,117	9,990	4,489
Gypsum.....	151,768	147,540	143,686
Iron ore.....	12,777,689	11,312,975	11,203,476

*Mineral Production of the United Kingdom—cont.*

Description of Mineral.	1891.	1892.	1893.
	Tons.	Tons.	Tons.
Iron pyrites.....	15,163	13,997	15,837
Lead ore.....	43,859	40,024	40,808
Manganese ore.....	9,476	6,078	1,336
Ochre, maber, &c. ....	13,502	12,131	10,534
Oil shale.....	2,361,119	2,089,937	1,953,520
Phosphate of lime .....	10,000	12,200	3,300
Salt.....	2,043,571	1,956,524	1,921,029
Slates and slabs.....	415,029	418,241	438,093
Strontian sulphate .....	8,061	5,066	5,812
Tin ore .....	14,488	14,329	13,689
Wollfram .....	138	125	22
Zinc ore .....	22,216	26,880	23,754

With a few exceptions the production shows a slight decrease in 1893. The great falling off in coal production was due to the miners' strike, and some comment will be found elsewhere.

The total number of mines reported in 1893 was 4,208, of which 3,383 mines, employing 683,008 persons, were classed under the "Coal Mines Regulation Act," and 825 mines, employing 35,739 persons, were under the "Metaliferous Mines Act." The total number of persons employed in mining was thus 718,747, of whom 5,760 were women, of whom 4,725 were at coal mines and 1,035 at

other mines. The mining employees were divided as follows:—

	Underground.	On Surface.	Total.
Males.....	570,978	142,000	712,978
Females.....	..	5,700	5,700
Totals.....	570,978	147,700	718,747
Totals, 1892.....	571,840	149,968	721,808
Totals, 1891.....	559,189	148,222	707,411

The total number of deaths resulting from accidents in and about mines last year was as follows:—

	Coal Mines.	Other.	Total.
Accidents underground.....	940	62	1,002
Accidents on surface.....	120	3	123
Totals.....	1,060	65	1,125
Totals, 1892.....	1,016	52	1,068
Totals, 1891.....	1,005	51	1,056

In the accidents underground, 160 deaths were caused by explosions of firedamp, 435 by falls of rock, and 115 were in shafts.—*Engineering and Mining Journal*.

#### MINERAL PRODUCTION OF CANADA, 1893.

The following summary of the mineral production of Canada during 1893 has just been issued by Mr. Elfric Drew Ingall, in charge of the Division of Mineral Industries and Mines. The figures are still held subject to revision:—

Product.	Quantity. <sup>(1)</sup>	Value.
<i>Metallic.</i>		
Copper (?).....	Lb. 8,102,856	\$75,864
Gold (?).....	Ozs. 51,609	927,244
Iron ore (?).....	Tons 124,702	298,918
Lead (?).....	Lb. 2,435,923	80,296
Nickel (?).....	.. 3,992,982	2,076,351
Platinum.....	Ozs. ..	1,800
Silver (?).....	.. 414,975	321,423
Zinc (?).....	Lb. 11,763	470
Total metallic.....	..	4,582,106
<i>Non-Metallic.</i>		
Asbestos.....	Tons 6,473	313,806
Coal.....	.. 3,719,17	8,422,259
Coke (?).....	.. 161,730	61,078
Felspar.....	.. 575	4,525

<sup>(1)</sup> Quantity marketed, except when otherwise specified. Tons are of 2,000 lb.

<sup>(2)</sup> Copper contents of ore, matte, &c., at 10¢ cents per lb.

<sup>(3)</sup> Nova Scotia and Ontario gold at 19'50 dols., Quebec at 18 dols., and British Columbia and Yukon District at 17 dols. per oz.

<sup>(4)</sup> Of this quantity 124,053 tons were converted into pig iron, producing 55,917 tons, valued at the furnaces at 790,283 dols.

<sup>(5)</sup> Lead contents of ores at 3'7 cents per lb.

<sup>(6)</sup> Nickel contents of ore, matte, &c., at 52 cents per lb. This represents the final market value of the nickel. In the matte its spot value would be much less, being quoted at 13 cents only in this condition, which would bring the figures for value down to 519,088 dols.

<sup>(7)</sup> Silver contents of ore at 76'9 cents per oz.

<sup>(8)</sup> Zinc contents of ore at 4 cents per lb.

<sup>(9)</sup> Oven coke, all the production of Nova Scotia.

#### MINERAL PRODUCTION OF CANADA, 1893—cont.

Product.	Quantity.	Value.
Fireclay.....	Tons 540	\$68,700
Grindstones.....	.. 4,000	38,570
Gypsum.....	.. 197,568	136,150
Limestone for flux.....	.. 27,737	27,510
Manganese.....	.. 228	14,458

Flaestones.....	Sq. ft. 40,800	3,487
Granite.....	Tons 22,521	94,393
Lime.....	Bush. 2,400,000	410,000
Marble.....	Tons 500	5,100
Pottery.....	..	189,107
Roofing cement.....	Tons 951	5,441
Sands and gravels (exports).....	.. 329,116	121,795
Sewer pipe.....	..	194,162
Slate.....	Tons 7,112	90,825
Terra-cotta (?).....	..	55,704
Tiles, M.....	16,000	191,000
Total non-metallic.....	..	14,394,294
Total metallic.....	..	4,582,106
Estimated value of mineral products not returned, largely structural materials.....	..	276,518
1893. Total.....	..	19,250,000
1892 ..	..	19,500,000
1891 ..	..	21,500,000
1890 ..	..	18,000,000
1889 ..	..	14,500,000
1888 ..	..	13,500,000
1887 ..	..	12,500,000
1886 ..	..	12,000,000

\* Estimated.

<sup>(1)</sup> See note (1) in preceding column.

<sup>(2)</sup> Exports, plus quantities sold to Canadian electrical works and stove foundries.

<sup>(3)</sup> Gross amount received through sale of gas.

<sup>(4)</sup> Calculated from inspection returns at 100 galls. crude to 38 refined, and computed at 1'04 dols. per bbl. of 55 imp. galls. The barrel of refined oil is assumed to contain 42 imp. galls.

<sup>(5)</sup> Exports, plus quantities sold to Canadian superphosphate works.

<sup>(6)</sup> Includes porous fire-proof terra-cotta.

—*Ibid.*

## THE MINERAL PRODUCTION OF GERMANY.

The following figures for the mineral production of Germany, including Luxemburg, for the year 1893, are given by the "Kohlen Zeitung," and have been prepared from the reports made by the various mines and works. The production is given in metric tons; the values we have reduced to dollars:—

	Quantities.		Values.	
	1892.	1893.	1892.	1893.
Coal.....	Met.Tons.	Met.Tons.	Dols.	Dols.
	71,372,193	73,908,399	131,714,794	124,616,605
Brown coal (lignite)...	21,171,857	21,567,218	11,626,475	13,759,759
Graphite.....	4,036	3,149	63,210	52,000
Asphalt.....	53,279	47,238	14,4713	89,215
Petroleum.....	14,527	13,971	219,941	195,733
Rock salt.....	662,577	669,042	708,046	736,929
Kainit.....	548,445	661,986	1,955,717	2,307,576
Other potash salts.....	892,639	861,162	2,532,169	2,562,060
Glauber salts.....	19,297	8,818	22,356	17,657
Boracite.....	179	181	13,614	11,289
Iron ore.....	11,539,013	11,157,491	19,319,713	9,950,111
Zinc ores.....	809,237	788,394	5,305,324	3,574,163
Lead ores.....	163,372	168,411	3,671,881	3,336,012
Copper ores.....	567,738	584,875	5,128,346	4,539,683
Gold and silver ores...	17,536	18,578	910,509	773,931
Tin ores.....	63	69	23,091	18,888
Cobalt, nickel, and bismuth ores.....	3,185	4,379	198,298	186,410
Uranium and wolfram ores.....	48	43	11,557	10,778
Antimony and quick-silver ores.....	..	16	..	100
Manganese ores.....	32,961	40,788	126,024	122,988
Arsenic ores.....	2,146	2,756	19,491	25,363
Pyrites.....	115,213	121,334	215,887	219,427
Other sulphur and alum. ores.....	2,973	791	2,916	1,250

The fuel production, it will be noted, showed only a moderate increase last year. The important minerals, iron, zinc, and lead ores, were substantially the same in both years. Prices generally showed a slight decline; coal, for instance, was valued at 1.68 dols. in 1893, against 1.84 dols. in 1892.

The products of the German salt works, an important item in the mineral industry of that country, were as follows:—

	Quantities.		Values.	
	1892.	1893.	1892.	1893.
Salt.....	Met.Tons.	Met.Tons.	Dols.	Dols.
	504,687	505,923	3,469,805	3,494,194
Potassium chloride....	123,362	137,216	4,109,559	4,396,285
Magnesium chloride....	14,386	12,764	59,578	44,443
Glauber salts.....	74,998	75,965	5,627,888	496,751
Potassium sulphate....	22,968	23,555	931,861	956,439
Double sulphate of potassium and magnesium.....	11,263	14,199	118,152	250,792
Magnesium sulphate....	23,879	27,518	84,008	79,240
Alumina sulphates.....	29,218	17,859	409,735	345,166
Sum.....	7,929	3,412	97,444	87,556

The chemical manufacture, as well as the mining industry, appears to have last year just about held its own, the average prices showing little variation.—*Ibid.*

## EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

## SWEDISH BEET SUGAR INDUSTRY.

## U.S. Consular Reports, 1894, 44, 704.

The sugar of Sweden is made from beets, and the following table shows the number of beet sugar factories in the Kingdom and their output for the 11 years 1882—92:—

Year.	Number of Factories.	Raw Sugar produced.	Year.	Number of Factories.	Raw Sugar produced.
		Tons.			Tons.
1882	1	1,472	1888	4	9,358
1883	2	1,367	1889	4	16,822
1884	2	3,655	1890	6	16,397
1885	3	3,940	1891	8	27,241
1886	3	5,958	1892	..	39,781
1887	3	5,953			

This sugar is all the product of beets grown in Sweden, and the increase in production is simply enormous. The amount of sugar consumed in Sweden is given in the following table, which shows the number of tons used for each year from 1883 to 1891. It must be borne in mind that the figures in the following table represent refined sugar, whereas those in the foregoing are for raw sugar. For purposes of comparison, 100 tons of raw sugar may be taken as equal to 99 tons of refined:—

Year.	Refined Sugar consumed.	Year.	Refined Sugar consumed.
	Tons.		Tons.
1883	38,294	1888	44,589
1884	49,753	1889	48,163
1885	41,253	1890	51,343
1886	11,392	1891	54,336
1887	42,651		

It will be seen that we have here to deal with an increasing consumption, as well as with an increasing output. Reckoning that the consumption will continue to increase in the same ratio as heretofore, we find that in the year 1896 Sweden will make use of 64,000 tons of refined sugar.

A careful estimate of the output of the Swedish factories, adding to the regularly increasing product of the 10 factories now in operation the probable product of four new factories just built or being built, shows that in 1896 there will be produced in Sweden 76,000 tons of raw sugar, equal to 68,400 tons of refined. Hence in 1896—the year after next—Sweden will probably produce not only sufficient sugar for its own inhabitants, but have a surplus for export.

It is true that the Swedish sugar beets are all raised in the southern portion of the country, and nearly all in a comparatively small section in the extreme south west. It is also true that the Gulf Stream, conveying the waters of the tropics to the north-west of Europe, gives to the Scandinavian peninsula a climate milder than that enjoyed by any other northern land. Still, after all allowances have been made, Sweden is an extreme northern country, with long winters, short summers, and in general a hard

soil. That in such a country the production of sugar should have advanced with such rapid strides and reached such grand proportions, constitutes one of the marvels of agriculture on our globe, and might well serve as an example and an incentive to the people of the United States, who live in a more fertile land and under milder skies.

### GENERAL TRADE NOTES.

#### THE AMERICAN CHEMICAL INDUSTRY.

##### *The Relation of Labour to the Cost of Production.*

The proportion of the cost of labour to the total cost of production in any branch of manufacturing industry is necessarily a serious consideration to manufacturers, especially where labour is an important factor in the industry. It is obvious that the supremacy in any given line of production must eventually lie with the country where, other conditions being equal, the cost of production is less than that of competing countries.

Germany is an important factor in this respect, so far as England is concerned; but the present article is not concerned with that country, but rather with the United States, where the chemical industry has of late years made steady progress.

It may be pointed out, by way of introduction, that the United States purchased, in 1893, chemicals, drugs, dyes, and medicines, to the value of 13,250,912 dols., of which 1,915,873 dols. was for coal-tar colours and dyes; 1,171,878 dols. was for caustic soda; 3,803,478 dols. for soda ash; and 4,401,000 dols. for miscellaneous chemicals. This was dutiable. The States also imported, during the same period, 1,444,620 dols. worth of chemicals duty free, among which were alizarine, argol, various kinds of barks, cochineal, &c. The export amounted, in 1893, to about half the total value of the imports of chemicals, namely to 7,001,000 dols. The value of the British exports of chemicals to America, in 1893, was 1,297,000*l.* (6,485,000 dols.) for alkali alone, or about 50 per cent. of the total value exported to all countries. Of bleaching materials, the States took 337,762*l.*, out of a total of 522,625*l.* We thus see the importance of the connection between the two countries, and any information bearing on the cost of production of chemicals in America must be of importance to English manufacturers.

The relation of wages to the cost of production involves a consideration of two elements—Labour and Capital, and two lines of inquiry may be pursued. First, the determination of the share of product which falls to labour in distinction from the share retained by capital. Secondly, the relation which labour cost bears to the total cost of production, as shown by the proportion which wages bear to the other elements of cost. The first inquiry would involve the question of profits, and would take as its basis the selling price of the product, separating the price into the various factors which compose it, such, for instance, as wages (labour's share) and profits and interest (capital's share). The second phase of the subject, which deals only with the actual cost to the manufacturer, eliminates profits, and determines what part of that cost is due to labour, represented by wages, and what to raw material and other necessary expenses. The first inquiry deals with the distribution of wealth, and the second with its production. The question to be dealt with next is, what relation does the cost of labour bear to the cost of the product at the actual time of completion? For instance, the proportions of cost in making 1,000 gallons of *disinfectants* are as follows:—Wages from 4.76 to 9.27 per cent. of the total, and raw materials from 95.24 to 90.73 per cent. respectively. In the manufacture of one ton of *sulphuric acid* the proportions are: Wages from 15 to 19 per cent., raw materials from 53 to 66.50 per cent., and miscellaneous expenses (such as rent, taxes, insurance, &c.) from 32 to 14 per cent. As regards laundry blue, to produce 24,092 gross of this article, costs from 13 to 22 per cent. for wages, about 59 per cent. for materials, and the balance for rent, &c. The labour cost of producing a ton of *guano* is comparatively small, being only 8.30 per cent. of the total outlay. The raw material costs 81.50 per cent., while

about 10.20 per cent. is allowed for general expenses. For the same quantity of *fertilisers*, the wages cost is 20 per cent., and materials 80 per cent. In the manufacture of *phosphates*, the labour cost per ton is a little higher, namely, 14.29 per cent. and materials 85.71 per cent. *Oils and illuminating fluids* cost, per barrel, nearly 7 per cent. for labour, about 67.50 per cent. for raw materials, and the balance goes for miscellaneous expenses. An experiment in making 3,185 tons of *copperas* shows that the labour cost ranges from 22.94 to 33.91 per cent., raw materials from 41.66 to 51.32 per cent., and general charges from 35.43 to 11.77. In making *mixed paints* (per gallon) labour costs about 10 per cent. of the total, and materials 90 per cent., while the same proportions apply to the manufacture of green paints.

In 1893, an investigation was made by the Statistical Bureau of the State of Connecticut, U.S.A., as regards the cost of manufacturing in that district, and particulars were obtained from 11 firms making *chemical products*, the aggregate capital being 438,000 dols.; the total value of goods made in one year amounting to 638,000 dols., the value of stock and materials being 359,300 dols.; the cost of manufacture (less rent, taxes, &c.), 156,550 dols.; rent and taxes, 6,988 dols.; superintendence, as distinct from "wages," 32,950 dols.; wages, 69,337 dols.; gross profits, 122,150 dols.; net profits, 115,161 dols., or a percentage of net profits of capital amounting to 26.29. Reduced to percentages these figures are:—Percentage of wages to the cost of goods made, 13.26; superintendence, 6.30; stock and materials, 68.72; rent, taxes, &c., 1.34; general expenses of cost of goods made, 10.38.

The following table shows the weekly rate of wages paid by nine firms to operatives in the State of Massachusetts, in the industry of making chemical preparations:—

Rates of Wages.	Employees.

In printworks, dyeworks, and bleacheries, in which 1,429 males were employed, 50 per cent. received 28s. to 32s. per week; 10 per cent. earned 1*l.*; 10 per cent., 24s.; 10 per cent., 36s., and the remainder sums varying from 2*l.* to 4*l.* In the chemical industries as a whole, 75 per cent. of the people earn about 2*l.* 5s. a week. Women rarely get beyond 30s., except in special cases of skill.

Mr. Charles Booth, when examining into the wages paid to persons employed in the chemical industry in England, found that out of 663 persons, two-thirds earned from 20s. to 40s. a week, so that it may be concluded that wages on both sides of the Atlantic are very similar. Mr. Booth found that foremen earn 40s. to 50s. a week, and "tending hands" make from 30s. and upwards, being paid 6*d.* to 7*d.* per hour. Chemical labourers are paid 5*d.* to 6*d.* per hour, or about 25s. for an ordinary week; but they, as well as the "tending hands," make a good deal of overtime. White lead workers earn 7s. 6*d.* a day, but the men do not work at this more than three days a week. Other persons employed get 4s. 6*d.* a day or 19s. to 22s. a week for such as have regular work. The cost of living in America, outside New York City, would be about 10 per cent. higher than in England, and this includes cost of clothing. Comparing New York City with London, the former would be about 20 per cent. dearer. Operatives work harder in America than in England, and there is rather more "driving" by the "bosses" there than in England. — *Chemical Trade Journal*.

#### THE IMPORTATION OF PATENT MEDICINES INTO TURKEY.

The following observations referring to the prohibition of the import of patent medicines into Turkey are contained in the report of the British Chamber of Commerce at Constantinople for the year 1892—93:—

Your Board is unfortunately unable to report that the prohibition referred to last year has been removed.

Further correspondence has been exchanged with Her Majesty's Embassy, and your Board is aware that Her Majesty's officials have striven to induce the Turkish Government to remove this arbitrary and prejudicial prohibition, but so far with no successful results.

On the 17th June, Sir Arthur Nicolson informed the Chamber that the Embassy had quite recently addressed two further notes to the Sublime Porte in regard to the questions of patent medicines and the banderolle tax, urging in the first case that some reply should be sent to the previous communications on the subject, and in the second requesting that the duty should be abolished as being distinctly contrary to treaty stipulations.

There is a curious feature in connection with this prohibition of patent medicines, which is the absence of this restriction at Smyrna, where all kinds of pharmaceutical

preparations are daily imported without hindrance, and it is no doubt the same in other Turkish ports.

#### NATIONALISATION OF THE GERMAN POTASH AND MAGNESITE DEPOSITS.

Probably animated thereto by the recent discoveries of new potash and magnesite mines in central Germany, the German Government have brought in a Bill for the nationalisation of all potash and magnesite deposits in the country. The output of potash and magnesia salts in Germany in 1892 was 1,361,161 tons, worth over 900,000*l.*—*Chemist and Druggist*.

#### THE PORCELAIN INDUSTRY AT LIMOGES.

According to the *Monde Economique* for the 14th April, the porcelain industry at Limoges is in a depressed condition. At the beginning of this year there were only 139 furnaces against 270 last year, with a diminished production of more than 40,000*l.*

#### CAUCASIAN MANGANESE TRADE.

The Belgian Consul-General at Odessa, in a recent report, supplies the following extract from an article which has appeared in the *Kharkoff Journal des Mines*:—

The owners of the manganese mines of Tchiatoura (Caucasus), have made a contract with the firm of G. Pincher, of Hamburg, for developing the working of manganese.

By the terms of this contract all the ore extracted is taken by the Pincher firm, which has the monopoly for sale to the European and American steelworks.

The quantity which will be annually delivered for consumption is estimated at 1,000,000 pounds at the least.

#### GERMAN IRON-MAKING AND ITS RESIDUAL PRODUCTS.

The advance of Germany as a great iron-producing country, and the strength of her competition in some of the markets of the world which British manufacturers have hitherto regarded as special fields of enterprise have awakened surprise, if nothing more. Twenty years ago, for instance, Germany's total make of iron was 885,000 tons, and of steel 125,000 tons, together 1,011,000 tons; while last year the total was 3,878,000 tons. Of this total one-third is bar and section iron; blooms, billets, and ingots making up 800,000 tons; plates, 425,100 tons; and rails, 891,400 tons. In recent years there have been cases of German iron and steel manufacturers quoting to British clients a lower price than home makers. It is assumed by some that the product is inferior, but where specific tests have to be met this is scarcely tenable. Labour may be slightly cheaper, but even this is doubtful, and certainly wages, especially to coal miners, are on the increase, so that fuel is dearer.

The growing importance of the iron industry in Germany is said by him to be due to two fundamental facts—the introduction of the basic process, which enables cheap and abundant native ores to be used, and the application of chemical skill to the recovery and utilisation of the by-products of coke manufacture. The latter point is of special interest, for, while there is a growing tendency to construct ammonia recovery works for the recovery of the products from the blast furnaces, little has been done in the case of coke making. The difficulty formerly urged was the possibility of injuring the quality of the coke. There are in all about 3,000 coke ovens which save the subsidiary products, and half of these are of the Otto and Otto-Hoffmann type. The oven more largely adopted in Belgium—the Seneet-Solvay—is cheaper to construct, but requires a special mixture of fat and lean coal, which is not always easy of arrangement, and while the coke made is of high and uniform quality, it gives less ammonia, tar, and gas than the German oven. The product from good coal containing from 15 to 17 per cent. of water is about 76 per cent. of coke, 1·15 to 1·25 per cent. of sulphate of ammonia, and from 2·5 to 4 per cent. of tar. Batteries of 60 ovens

in three districts gave the following results in pounds per ton of coal:—

	Coke.	Tar.	Sulphate of Ammonia.
Ruhr .....	1,672	60.5	25.3
Silesia .....	1,436	93.5	26.4
Saar .....	1,749	91.4	18.7

These 180 ovens produce per annum 139,800 tons of coke, Ruhr making 51,300 tons, Silesia 48,000 tons, and Saar 40,500 tons. The aggregate sulphate of ammonia recovered weighed 2,112 tons and the tar 7,260 tons. Moreover, the waste heat, after the recovery of these by-products, was sufficient to work the ovens and give a large surplus for other purposes. This surplus in the case of Ruhr was 12,800 cubic feet per oven per day, Silesia 16,000, and Saar 12,800 cubic feet. In other words, a battery of ovens, in addition to providing the coke and the residual products, self-heating, and gives off per day heat which is equivalent to 45,600 lb. to 57,000 lb. of coal, sufficient to run machinery indicating from 1,200 to 1,600 indicated horse power. Of course, a special plant is necessary to work the process, so that in making comparison with the ordinary coking establishment, allowance must be made for this extra first cost.

The approximate gross value of the process is easily obtained. Taking the case of Silesia, we find that in producing 48,000 tons of coke in the ovens, 3,000 tons of tar are recovered each year, which at 2s. per cwt. yields 6,000*l.*, and 840 tons of sulphate of ammonia, at 11s. per cwt. equals 9,240*l.*—together, 15,240*l.* To this amount must be added the fuel saved. In Silesia the total production of gas is 36,800 cubic feet per oven per day, and after consuming 20,800 cubic feet in roasting the coal in the production of the coke, a surplus of 16,000 cubic feet remains for other purposes, equal, as we have already indicated, to 57,000 lb. of coal for the 60 ovens, sufficient for 1,600 i.h.p. during 18 hours per day at 2 lb. per i.h.p. per hour. The value of this coal—about 9,000 tons per annum—should be added to the 15,240*l.* received for tar and sulphate of ammonia, in determining the gross value of the residual products. This does not include the value of the heat utilised in the oven, which is equivalent to an additional 12,000 tons per annum. Sixty ovens in Westphalia cost in construction 34,500*l.*, or 576*l.* each, and the tar and sulphate of ammonia produced in one year's working provided a revenue of 8,375*l.*, or about 25 per cent. on the capital invested in the plant.

The other instances given might also be worked out, but it is probably sufficient to show that Germany can afford to credit actual cost of production with a large sum, the result of the recovery and sale of by-products. Of course this affects the selling price of their iron and steel, and offers at least a partial explanation for the low quotations made by German makers in competition with British manufacturers. The influence on the price of tar and ammonia of the 3,000 ovens in use in Germany and Austria is pronounced. In 1883 sulphate of ammonia was worth 16s. per cwt., but now sells at 11s., and tar has dropped in price from 3s. to 2s. per cwt. The decline in prices is not alarming, however, as in Westphalia four years' revenue suffices to pay the plant.—*Engineering and Mining Journal*.

#### THE NITRE QUESTION.

H. Polakowsky. *Chem. Ind.* 17, 86—88.

In this paper German capitalists are encouraged to participate in the forthcoming great sale by the Chilean Government of the nitre deposits in Northern and Central Tarapaca, and thus to prevent an English monopoly of the nitre market, to the detriment of the German consumption, which latter amounts to one-third of the world's consumption! About three-fourths of the deposits already sold by the Government are in English hands; the property now on sale embraces one-fourth of the nitre deposits still owned by the State in the province of Tarapaca.

The law enacting the sale of these deposits contains the following regulations (*Diario Oficial*, November 29, 1893, Law 127): Sect. 1 authorises the sale of 37 "oficinas" (nitre deposits with corresponding buildings and apparatus) within five years. The Government having undertaken to redeem the whole of the paper money by June 30, 1896, and the proceeds from the sale of these deposits being intended for such redemption, it is likely that the sales will be proceeded with shortly. Sect. 2 enacts the sale of certain specified deposits without "oficinas." Sect. 3. The sale is advertised six months beforehand in the *Diario Oficial* and three months beforehand in the principal newspaper in London, Paris, Berlin, and New York. Sect. 4. The appraised value to be the lowest bid. Sect. 5. Payments to be rendered in pounds sterling or in good acceptances in London (30 days). Twenty per cent. of the purchase money payable at once, 30 per cent. at the end of 1894, and 50 per cent. at the end of 1895. Sect. 6. A guarantee amounting to 40 per cent. of the appraised value has to be given. On payment of the first two instalments the guarantee is reduced to 20 per cent. Sect. 7. The deposits are sold according to the plans of the "Delegación Fiscal de Salitras." Sect. 8. The State is responsible for the claims of third parties. Sect. 9. In case of boundary disputes the buyers to have the right of calling in the decision of the court. Sect. 10. The proceeds from the sales, up to 1,500,000*l.*, to remain in the keeping of the mint. Sect. 11. The suspension of the law of 26th January 1893 referring to the sale of nitre deposits is enacted.

The property on sale consists of 57 deposits provided with "oficinas" (the latter are out of use since 1879 and will be next to valueless) and of 24 deposits without "oficinas." The first sale takes place on June 15, 1894, when one-third of the deposits, situated in the northern part of Tarapaca, will be put up. The appraised value of this lot amounts to 700,000*l.* out of a total of 1,500,000*l.*

—H. A.

#### EXPERT OPINIONS FROM THE PAPER TESTING DEPARTMENT OF THE BERLIN EXPERIMENTAL INSTITUTES.

*Mitt. Königl. techn. Versuchs.* 11 '93, 248—256.

It frequently happens that the tribunals apply to the Institute for expert opinion on matters connected with paper. Such opinion is required for the purpose either of settling disputed questions between litigants, or of supplying some link in the chain of evidence in cases where punishment is inflicted. Seven typical cases are cited and the following conclusions are drawn:—No careful manufacturer should accept an order to be executed "exactly according to sample." In settling the conditions of delivery, it would be better to rely less upon the sample than upon a clear statement of the nature and strength of the raw materials to be employed. Above all, such general definitions as "extra strong," "durable," "extra hard sized," &c., should be avoided. Parties are also recommended before going to law to obtain the opinion of an expert on the matters in dispute, as it seldom happens that the judge himself can arrive at a conclusion without reference to expert opinion. The question is finally asked: "Would it not be better to avoid altogether the tedious and costly method of settling trade disputes by litigation, and rather to submit them at once to a tribunal of scientifically and practically trained experts?"—E. G. P. T.

#### PURCHASING SILVER, GOLD, AND LEAD ORES.

H. Van Furman. *School of Mines Quarterly*, 15, 1893, 1—7.

Competition between the smelters of Denver, Pueblo, and Salt Lake City, the growing scarcity of desirable flaxing ores, and (late) the declining price of silver, have led to a complex system of valuation, which takes into account, besides the assay value of the ore, its chemical composition, the assumed losses in treatment, the cost of roasting and of smelting (including cost of fluxes, fuel, and labour), the mechanical condition of the ore, the particular desirability of the lot, and the market values of the metals at the time of purchase. The assay-value of the gold, silver, and lead

is always determined by fire assay. Copper when present is determined by volumetric or electrolytic methods. The necessity for determining the silica, iron, &c., is judged of according to the apparent mineralogical composition of the ore, and charges or allowances are made on a sliding scale based upon an equality of silica and iron—the so-called neutral basis. Silica is charged or allowed for at the rate of 15 cents per unit above or below the iron present. Manganese is reckoned as iron. 6 cents per unit is allowed for all fine magnesia, and baryta; zinc below 8 per cent. is not charged for; all above that is charged 50 cents per unit. Special deductions are sometimes made in the case of arsenic. The losses of gold and silver in treatment are usually assumed at 5 per cent. Payment is calculated on New York prices. Lead is paid for on the following scale, based upon a New York price for pig lead of 1 dol. per 100 lb.:—

Under 5 per cent., payment nothing.			
5 per cent. and under 10, payment 25 cents per unit.			
10	"	20	35
20	"	30	40
30	"	40	45
40	"	50	50
50	"	and over	55

The cost of roasting varies with the chemical and mechanical condition of the ore, the kind of furnace used; the cost and amount of labour, &c., from less than 1 dol. up to 2.75 dols. per ton.

The cost of smelting also varies greatly, additions and allowances being made as above, but the charge is based on 4.50 dols. per ton for an assumed neutral ore.

Examples are given of calculations in special cases, according to the foregoing data.—J. H. C.

#### THE BRADFORD CONDITIONING HOUSE.

*United States Consular Reports, May 1894, 2—7.*

A conditioning house is an establishment in which the true weight, length, and condition of articles of trade and commerce are determined scientifically. This is a matter on which there has always existed a difference of opinion between British exporters and American importers. Though England and the United States use the same weights and measures, there are invariably differences between the weights and measurements of yarns, wools, and pieces, from the time of their shipment from this point and their final distribution in America; so great, in fact, as to have a considerable bearing on the profits of the transaction. Certain exporters have a definite understanding of some kind with their American clients on this subject, and manage to evade serious difficulty. Others, however, have constant friction, and only recently one of the largest exporting houses in Bradford was compelled to allow an American customer a 5 per cent. discount because of the shrinkage in a large invoice of goods, though it was alleged by the exporter that it entirely obliterated the profits of the transaction. All this may be prevented by the importer of either raw material, partly manufactured, or wholly finished goods, demanding that the product be accompanied by a certificate from a legally authorised conditioning house. As a rule, the charges would be light; but they would be added to the price of the goods, unless there was a distinct understanding to the contrary. Another plan would be for the establishment of a conditioning house in New York, or any other American port of entry, for the purpose of conditioning goods there on exactly the lines followed here. The system would be equally useful for testing and conditioning American and foreign goods.

#### *The Bradford Establishment.*

The conditioning house here is owned and operated by the municipality. It is the only one in England, and was established three years ago under the Parliamentary Act of 1877. The idea originated with the Bradford Chamber of

Commerce, and was adopted by the corporation on that body's suggestion. Its popularity has been of steady growth, and last year the business transacted was twice that of the previous year. Merchants and spinners engaged chiefly in the home trade are now making great use of it for the testing of bulk lots of wool, tops, yarns, and waste. The tests on this account alone amount to 45 per cent. of the total business transacted, the remaining 55 per cent. of the business of the enterprise being export trade. A large percentage of the tests are made to settle disputes, the certificate of the conditioning house being accepted as a basis of arbitration. Bradford is fortunate in having, as manager of the concern, a gentleman of splendid scientific attainments, who is an enthusiast in the business, and who understands thoroughly the very complicated machinery used in making the tests. Tests are made by the exact and logical metric system, and the results then rendered into the English weights or measurements. They are also figured direct by the English system. Being worked under Parliamentary Act, all certificates granted are legal evidence in a court of law, and are accepted as absolutely correct as to weight, condition, and description of goods, on the date such goods passed through the conditioning house. The objects to be effected are to determine:

- (1) The average amount of moisture contained in wool, tops, noils, and yarns submitted for examination.
- (2) The correct gross weight of bales, bags, cases, skeps, sheets, and packages of goods, and the tare thereof.
- (3) The net conditioned weights of sample lots of wool, tops, noils, and yarns, after scouring, clauing, and drying.
- (4) The true counts, lengths, twists, and strengths of yarns.
- (5) The measurement of length in piece goods.

The system adopted is much the same as that in general use on the Continent. In France, Germany, and in many other countries of Europe there is a large number of these institutions, some of colossal size, notably the one at Roubaix, where about 100,000,000 kilograms of material are "conditioned" annually. As has been stated, the Bradford House, though of recent origio, is meeting with popular favour, both for home and export trade, and is being used as a means of ascertaining and accepting "the correct invoice weight" of goods at the normal (official) condition. Many other branches of testing are undertaken for the settlement of disputes and claims. The tests are made with every care that science and experience can suggest, and by the use of the best machinery and testing apparatus. I was struck with wonder in making a tour of the establishment. The puzzling machinery, the drying of wool in hot receptacles, the mazes of yarns being tested for strength, the piles of different material, the clicking and ticking of curious instruments, all combined, are calculated to have a mystifying effect upon a novice. All tests are made in duplicate, and the results and calculations worked out by separate methods and separate persons, so as to insure perfect accuracy. An official certificate is given showing the result of each test. The strictest confidence is observed, and the results of tests are made known only to the persons who send the articles to be tested. Although the official condition is given only for bulk lots—that is, when the whole consignment has been sent to the conditioning house—a special note marked "Sample Test Note," is given for samples drawn by the buyer or seller elsewhere.

#### *How Tests are made.*

On the arrival of the bulk lots, the gross weights of the sheets, bales, bags, or packages, are taken by two persons independently. The tares, if it be so desired, or if it be practicable, are taken in the same manner. A certain number of samples are then drawn for the purpose of testing their condition, and the bulk can at once be taken away. The official certificate will follow, by post or otherwise, as soon as practicable on the completion of the tests and

Nitrate of soda... "	5,171	25,539	53,975	247,386
Phosphate of lime .. "	14,911	19,553	24,463	32,264
Paraffin..... Cwt.	73,102	54,416	76,179	53,862
Linen rags..... Tons	349	1,649	1,890	15,987
Esparto..... "	18,185	19,089	87,921	84,514
Pulp of wood .... "	18,391	21,421	99,842	114,175
Rosin..... Cwt.	101,625	97,856	22,299	18,711
Tallow and stearin .. "	148,369	224,979	269,862	291,187
Tar..... Barrels	2,650	2,084	1,517	2,096

IMPORTS OF RAW MATERIAL FOR NON-TEXTILE  
INDUSTRIES FOR MONTH ENDING 30TH APRIL—cont.

Articles.	Quantities.		Values.	
	1893.	1894.	1893.	1894.
			£	£
Wood:—				
Hewn ..... Loads	153,167	226,239	288,480	354,781
Sawn ..... "	165,939	246,871	359,730	378,500
Staves ..... "	8,921	9,024	52,673	46,298
Mahogany ..... Tons	8,445	3,902	78,225	28,599
Other articles.... Value £	..	..	929,794	779,316
Total value .....	..	..	2,911,545	3,597,399

Besides the above, drugs to the value of 64,975*l.* were imported, as against 80,363*l.* in April 1893.

EXPORTS OF METALS (OTHER THAN MACHINERY) FOR  
MONTH ENDING 30TH APRIL.

Articles.	Quantities.		Values.	
	1893.	1894.	1893.	1894.

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

7492. C. F. Young. Improvements in agitators or stirrers for pans in which liquids, starch, and other pastes, colours, and other substances are heated or cooled. April 16.

7626. W. Bagley. Improvements in apparatus for feeding coal to gas producers. April 17.

7651. W. Lawrence. Improvements in processes and apparatus for drying organic and inorganic substances, or in extracting the moisture from brewers' grains, earthy substances, or solutions of salts, and such like. April 17.

7893. J. T. Sands. Improvements in apparatus for bleaching smoke. Complete Specification. April 21.

8545. C. G. J. Möller and P. Pfeiffer. Improvements in and relating to drying and evaporating apparatus. April 30.

8643. C. L. W. Albach. Improvements relating to the lixiviation of dyewood, bark, hops, and other materials, and to apparatus therefor. May 1.

9049. E. A. Uehling and A. Steinbart. Improvements in and relating to processes and apparatus for analysing gases and gaseous mixtures. Complete Specification. May 7.

9186. W. Cliff and M. Mannaberg. Improvements in apparatus for calcining lime, dolomite, and the like. May 9.

9198. B. G. Davis-Cooke. Improvements in the method of manufacturing ganister for the lining and repair of cupolas, furnaces, and other similar purposes, and the manufacture of bricks and other fireclay goods from the same. May 9.

9210. E. Cramer. Improvements in kilns for burning cement and other minerals. Complete Specification. May 9.

9395. T. E. Pye and C. E. Seull. Improvements in valves or regulators for gas and chemical works.

### COMPLETE SPECIFICATIONS ACCEPTED.\*

#### 1893.

10,467. E. Latham and E. G. Guyot. Improvements in apparatus for evaporating liquids by means of steam. May 16.

10,870. J. Fischer. Improvements in apparatus for cooling, heating, drying, or similar purposes. May 9.

12,018. J. Clarkson and S. Mortimer. Improvements in apparatus for supplying air and steam to furnaces so as to effect a more complete combustion of fuel and prevent the formation of black smoke. May 9.

12,774. F. W. Scott, E. G. Scott, and F. W. Scott, jun. Improvements in evaporating brine and other liquors, and apparatus therefor. May 9.

12,972. A. Horn. New or improved cooling apparatus. May 9.

13,146. F. Spence. A new or improved hydrostatic apparatus for automatically mixing with water or other liquid disinfectants, softening or purifying substances in definite proportions. May 16.

18,652. C. Latarche. An improved actinometric pyrometer. May 9.

#### 1894.

1377. C. Morel and A. Heimpel. Improvements in apparatus for crushing dry or wet materials, such as cements, lime, plaster, alabaster, kaolin, quartz, phosphates, minerals, and the like. April 25.

5262. W. Henneberg. Improvements in apparatus for condensing vapours and heating or vaporising liquids respectively. May 16.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

7527. C. Barker. An improved fire-fighter for lighting coal or coke fires. Complete Specification. April 16.

7599. J. A. A. Nyström. An improved fire-lighter. April 17.

7772. G. S. Cory and C. Cory. Improvements in the manufacture of artificial fuel. April 19.

7827. C. E. Jolly and H. J. Reid. Improvements in machinery or apparatus for the manufacture of briquettes from fuel material. April 20.

7911. R. Middleton. Improvements in machinery for manufacturing blocks or briquettes of fuel or materials for smelting and analogous purposes. April 21.

8998. L. Dardel and H. Bécoulet. An improved solid combustible and process of manufacturing the same. April 24.

8117. J. Posno. Improvements relating to the treatment of sewage and town refuse for transforming the same into fuel. April 24.

8598. H. J. P. Sprengel. Improvements in obtaining oxygen. April 30.

8588. A. G. Glasgow. Improvements in water-gas apparatus. Complete Specification. May 1.

8670. B. H. Thwaite. Improved method of utilising the waste gases from iron-smelting blast-furnaces. May 2.

8851. J. H. Hilton. Improvements for carburising coal and other gases. May 4.

8974. T. G. McEwen. Improvements in the manufacture of gas. May 5.

9197. H. Hawkins and S. H. Hawkins. Improvements in the production of hydrocarbon gas and metal sulphates as by-products, and in apparatus therefor. May 9.

9274. E. Stauber. Improvements in the process of and apparatus for producing peat briquettes and the like. May 10.

9387. C. Schmitz. Improvements in or relating to the combustion of fuel. May 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

8499. E. Hedges. Improvements in the manufacture of fire-lighters. May 2.

10,554. The Manchester Oxygen (Brin's Patent) Co. and W. M. Jackson. Improvements in and in the mode of utilising the pressure in cylinders or reservoirs of compressed gases, in the application or employment of such gases. May 16.

11,961. H. W. Crowther. Improvements in the treatment of the waste from gas-liquor to obtain useful products therefrom. April 25.

12,247. A. Norreys. Improved means or process for producing block fuel. May 9.

22,576. F. D. Marshall. Improvements in apparatus for washing and purifying gas. May 9.

1894.

1690. B. H. Thwaite and G. Threlfall. Improvements in methods and apparatus for generating gaseous fuel from solid hydrocarbonaceous or carbonaceous material. April 25.

#### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

##### APPLICATIONS.

7862. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the purification of anthracene. April 20.

8371. J. Bryson, J. Jones, and W. Fraser. Improvements in or relating to retorts for the distillation of shale and other bituminous substances. April 27.

#### IV.—COLOURING MATTERS AND DYES.

##### APPLICATIONS.

7540. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of dyestuffs. April 16.

7786. H. H. Lake.—From Wirth and Co., Agents for A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. April 19.

7859. C. D. Abel.—From The Actien-Gesellschaft für Anilin-Fabrikation, Germany. Manufacture or production of colouring matters and materials therefor. April 20.

8381. C. D. Abel.—From The Actien-Gesellschaft für Anilin-Fabrikation, Germany. Manufacture of a new naphthylendiamine mono sulpho acid, and of colouring matters derived therefrom. April 27.

8536. E. Petersen-Müller. Manufacture of colouring matters, dyeing un mordanted cotton, and their salts and sulpho-derivatives. Complete Specification. April 30.

8541. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of phenol alcohols. April 30.

8564. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of new azo colouring matters. April 30.

8867. J. H. Lütkehermölle. New bases from benzidine, zolidine, &c. May 1.

9291. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture of artificial indigo-white and of bodies related to the indigo group. May 10.

9441. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of dyestuffs. May 12.

9443. J. Imray.—From R. Vidal and La Société Anonyme des Matières Colorantes et produits Chimiques de St. Denis, France. Manufacture of colouring matters applicable to un mordanted fibres or fabrics. May 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

8093. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of dyestuffs. March 28.

10,996. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The manufacture and production and application of new colouring matters or dyes from naphthalene. May 2.

11,892. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of dyestuffs. April 25.

13,394. H. E. Newton.—From the Farbenfabriken vormals F. Bayer and Co. The manufacture of new leuco compounds and the production of colouring matters therefrom. May 16.

13,395. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of colouring matters by reduction of tetranitroanthrachry-one and dinitroanthrachrynone-disulphonic acid. May 16.

13,402. H. H. Lake.—From K. Ochler. Improvements relating to the production of amidophenol and amidoeresol-sulpho acids, and to the manufacture of colouring matters therefrom. May 16.

13,419. A. Ashworth and J. Burger. Improvements relating to the production of colouring matters. May 16.

1894.

5143. R. Korff. Manufacture of new amido bases and of azo colouring matters therefrom. May 2.

5870. J. Grime. A new or improved method of oxidising jigo fibres and the like, and apparatus employed therefor. April 23.

6004. F. Muhlert. Manufacture of yellow and orange colouring matters from *B-resorcylic acid*. May 2.

## V.—TEXTILES, COTTON, WOOL, SILK, Etc.

### APPLICATIONS.

7642. A. V. Newton.—From A. Nobel, France. Improvements in the manufacture of artificial silk and substitutes for vegetable fibre. April 17.

7690. T. Bedford and F. Bedford. An improved process of preparing rhea or ramie fibre, and in the manufacture of ropes and twines therefrom. April 18.

7907. W. Pickstone and A. Greenhalgh. Improvements in and relating to the manufacture of crinkled textile fabrics. April 21.

7975. O. Reichenbach. New or improved apparatus for use in degreasing or otherwise cleansing wool or other fibres. April 23.

8038. D. E. Radclyffe. Improved apparatus or method or system for preparing china, grass, or rhea fibre, or hemp, or similar fibres, for combing or spinning. April 24.

8893. E. Cadoret and A. Jost. An improved process for treating vegetable substances suitable for the manufacture of woven fabrics, by converting them into soft and silky fibres adapted for spinning and dyeing. May 4.

### COMPLETE SPECIFICATIONS ACCEPTED.

1891.

3484. O. Reichenbach. An improved process and apparatus for cleaning wool and other textile products. May 2.

4396. J. S. Farmer, H. L. Storey, and I. H. Storey. Improvements in the manufacture of solid-colour floorcloths, and in machinery employed in such manufacture. May 15.

5718. H. Rous and G. N. West. A new or improved process for rendering textile materials waterproof and flameproof. April 25.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

### APPLICATIONS.

7650. F. G. Armfield. See Class XIV.

7885. J. S. Lord and G. S. Lord. Improvements in machines for washing, scouring, mordanting, bleaching, sizing, and dyeing yarn in the hank. April 21.

8278. A. Whittall. Improvements in apparatus for dyeing yarns. April 26.

8558. E. Cadoret and A. Vost. Improvements in the process of and apparatus for bleaching and treating fibrous materials and fabrics. April 30.

8767. F. Barraclough. Improvements in machines for scouring and dyeing textile warp or other yarns. May 3.

8964. J. W. Abom. Method of bleaching paper pulp, or other flecky substances. Complete Specification. May 5.

8969. G. N. Midwood and C. Edmeston. Improvements in dyeing and otherwise treating cotton and other piece goods, and in machinery or apparatus to be used for the purpose. May 5.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

9371. C. D. Abel.—From The Farhwerke vormals Meister, Luthius, and Brauning. A process for dyeing wool with fast colours. May 9.

11,891. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The production of colours on fibres. May 16.

11,929. J. Riley and The Thornliebank Company, Limited. Improvements in the bleaching or cleansing of vegetable yarns and fabrics. April 25.

12,076. J. Grime. Improvements in vats for dyeing indigo-blues and the like. April 25.

12,367. L. Frakenburg and C. O. Weber. Improvements in or connected with the producing or printing of designs upon waterproof fabrics. May 2.

15,083. H. H. Lake.—From E. Michaelis and Co. An improved process for dyeing textile materials. May 2.

1894.

7641. W. H. Hughes and S. F. Hughes. Improved process for scouring, cleansing, bleaching, and disinfecting wool and other fibres or fibrous materials. May 16.

## VII.—ACIDS, ALKALIS, AND SALTS.

### APPLICATIONS.

7554. G. T. Beilby. The manufacture of cyanides. April 17.

7578. F. Hamer. The production of nitric acid  $\text{HNO}_3$ , and the nitrates of soda, of potash, and of lime. April 17.

7603. C. J. Hammerton. See Class XI.

7636. A. Shearer and R. R. Clapp. Improvements in the manufacture or production of phosphorus and compounds thereof. April 17.

7671. C. M. Pielsticker. Improvements in the production of sodium and potassium. April 18.

8048. R. Hodgson. A new or improved process and apparatus for the manufacture of salt. April 24.

8305. H. W. Crowther, E. C. Rossiter, J. J. Hood, and G. S. Albright. Improvements in the manufacture of ferrocyanides of potassium and sodium from their sulphocyanides, and apparatus relating thereto. April 26.

8652. R. H. Leaker. Improvements in the manufacture of vinegar. May 2.

8690. H. Fielder. Improvements in apparatus for and process in the manufacture of chlorate of potassium. May 2.

8889. O. Imray.—From Goerlich and Wichmann, Germany. An improvement in the manufacture of cyanides of the alkaline metals. May 4.

9004. J. F. Hutcheson. Improvements in the manufacture of acetate of lead. May 7.

9197. H. Hawkins and S. H. Hawkins. See Class II.

9250. R. Hodgson. Improvements in machinery or apparatus for obtaining salt from brine. May 10.

9275. H. W. Crowther, E. C. Rossiter, and G. S. Albright. Improvements in the manufacture of cyanides. May 10.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

9521. W. V. Wilson and J. J. Lundy. Improvements in the manufacture of sulphate of lead. May 16.

12,572. J. Addie, J. Cunninghame, and W. Macfarlane. Improvements in the production of cyanides. May 9.

13,655. F. Maxwell Lyte and G. Lunge. Improvements in the production of caustic alkali and chloride of lead for conversion into chlorine and refined lead. May 16.

13,656. G. Lunge and C. H. Maxwell Lyte. An improved process for producing basic lead salts and obtaining certain by-products. May 16.

13,842. T. Chaudelon. New process for the preparation of bieleite phosphate soluble in ammoniac citrate. April 25.  
13,927. A. Müller. An apparatus for obtaining carbonic acid. May 9.

15,475. R. H. Leaker. Improvements in the manufacture of vinegar. May 2.

19,705. B. K. Rigby, F. A. Remington, and A. C. Carr. See Class IX.

1894.

5808. J. D. Darling and H. C. Forrest. Improvements in producing nitric acid and metals from nitrates. May 2.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

### APPLICATIONS.

8076. D. Jones, W. W. Wardle, F. C. Wardle, and A. W. Beech. Improvements in ornamenting china, earthenware, and other brittle articles. April 21.

8523. A. Mason and H. E. Mason. Improvements in the manufacture of fireclay tuyères and apparatus for effecting same. April 30.

8575. J. Hughes. An improved method of decorating on pottery. May 1.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

8555. A. D. Brogan.—From The Glasgow Plate Glass Co. Improvements in apparatus for rolling glass. May 2.

11,098. H. Tugby. Improvements in the manufacture and production of stoneware sanitary pipes and the like. May 9.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

8468. A. W. Keim. An improved material for wall-plastering, priming, casting, or the like, and process for producing the same. April 28.

8175. J. L. Kerr. Artificial plaster of Paris, made from the lime residue resulting from the reduction of sulphate of ammonia. April 28.

8549. R. Stone. Improvements in the manufacture and treatment of fire-proof plastic material for cement. Complete Specification. April 30.

8977. G. Beekert. Improvements in building blocks and slabs. May 5.

9455. R. Hauers. Improvements in the preservation or treatment of buildings, structures, building materials, and the like from dirt or decay. May 12.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

9550. R. Haddan.—From G. R. Anderson, A. H. Shotton, W. Koehler, and C. H. Dover. An improved artificial asphaltum or pitch, and process of making same. May 16.

12,468. Goegg, Fruh, and Co. Improved decorative material on surface in imitation of marble. May 2.

13,598. J. Fisher. Improvements in and connected with concrete and similar pavements and floorings. May 16.

19,705. B. K. Rigby, F. A. Remington, and A. C. Carr. Improvements in the manufacture of cement from Chance or Le Blanc alkali waste or the like. April 25.

1894.

2582. C. H. Slicer. Improvements in and relating to the production of asphaltic composition in the form of a powder or of a mastic. May 2.

4223. P. Baumert and A. Meck. Improvements in grinding or pulverising machines. May 2.

5595. C. A. Ropes and J. C. Sellars. Improvements in or connected with cements or cement work. April 25.

## X.—METALLURGY, MINING, ETC.

### APPLICATIONS.

7672. C. M. Pielsticker. Improvements in the production of metal alloys. April 18.

7854. W. A. Thoms and W. H. Burgum. An improvement in the coating of metals with a metallic alloy. April 20.

8085. P. C. Choate. Improvements in the art of producing metallic zinc. Complete Specification. April 24.

8087. A. A. Ackerman. An improved process for the manufacture of hard-face armour plate. Complete Specification. April 24.

8136. H. W. Gablett-Fairfax. Improvements relating to methods of and apparatus for hardening or tempering steel plates and other articles. April 24.

8183. W. P. Thompson, From L. R. Bonehill and E. T. Gantier, Belgium. Improved process and apparatus for extracting metals from their ores. April 25.

8184. J. S. MacArthur. Improvements in precipitating precious metals from cyanide or similar solutions. April 25.

8306. C. T. J. Vautin. An improved process for the extraction of metals from oxides and sulphides. April 26.

8370. B. P. Stockman. Improvements in the manufacture of steel and iron. April 27.

8401. H. Ramage. Improvements in or connected with the preparation or coating of aluminium surfaces, and in alloys or metallic mixtures therefor, and for soldering. April 27.

8405. H. L. Salzman. Improvements in or relating to the treatment of ores. April 27.

8586. C. M. Allen. Processes of and converters for smelting and refining ores. Complete Specification. May 1.

8712. J. Brock and J. F. Allen. Improvements in the manufacture and production of alloys of copper and manganese. May 2.

8790. M. T. Brown.—From J. C. Preston, Australia. A method of and apparatus for the extraction of gold and silver from their ores or tailings. May 3.

8899. H. F. Taylor. Improvements in apparatus for coating with tin, lead, or other metals or alloys of same. May 4.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

2639. J. A. Mays. Process of and apparatus for separating metals and similar substances. May 16.

10,608. D. W. Sugg. An improved metallic alloy. May 2.

11,709. J. B. Cochrane and T. H. Taylor. Improvements in the purification of iron for casting and general foundry purposes, as also in the production of steel and wrought iron. May 16.

12,034. G. Bischof. Improvements in the treatment of lead fumes. May 16.

1894.

5530. E. Singer, F. Donat, and P. Kirchseisen. Process for soldering aluminium. May 9.

5808. J. D. Darling and H. C. Forrest. See Class VII.

## VI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

7603. C. J. Hammerton. Application of electricity to the manufacture of cyanides and ferrocyanides and improvement in same. Preservation of vessels from corrosion. April 17.

7801. C. Kellner. Improvements in or relating to electrolytical apparatus. April 19.

7853. W. A. Thoms and W. H. Burgum. An improvement in the electro-deposition of heavy metals with a base metal alloy. April 20.

7865. D. G. Fitzgerald and A. W. Southey. Improvements in the construction and working of galvanic batteries. April 20.

7950. H. Guthrie. Improvements in apparatus for electrolytical purposes. April 21.

7985. T. Drake. An improved method, means, or process of producing caustic soda and chlorine gas by the electrolysis of common salt in solution. Complete Specification. April 23.

7994. E. de Pass.—From H. Thofehn, France. An improved electrolytic trough or cell. April 23.

8061. H. Carmichael. Improved apparatus and process for electro-chemical decomposition. Complete Specification. April 24.

8350. H. H. Leigh.—From Vohwinkel, Austria. Improvements in electric batteries. April 27.

8480. T. H. Rushton. Improvements in and relating to galvanic batteries. April 28.

8731. T. Froggatt. Improvements in electric batteries. May 2.

8808. R. McLauchlan McDonald and A. McDonald. Improvement in electric batteries. May 3.

8815. L. Mond and R. L. Mond. Improvements in electrolytic cells.

8895. F. King. Improvements in or connected with secondary or electric storage batteries. May 4.

8917. H. Alexander. Improvements in or in connection with apparatus for the electro-deposition of metals. Complete Specification. May 4.

8972. F. Griffin. Improvements in or relating to secondary batteries. May 5.

9129. H. Blumenberg, jun. Improvements in electrolysis. May 8.

9285. C. Kellner. Improvements in or relating to electrodes and method of manufacturing the same. May 10.

9292. E. A. Allen. Improvements in or connected with electrolytic cells. May 10.

9328. B. Hooker. An improvement in and relating to apparatus for electrolysis. May 11.

9363. F. Brain. Improvements in electric fuses. May 11.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

7906. D. G. Fitzgerald. Improvements in the manufacture of elements or electrodes for voltaic batteries and electrolytic decomposition cells. May 16.

12,857. J. C. Richardson. Improvements in and connected with tanks for the electrical decomposition of chloride of sodium or potassium in solution. May 9.

13,318. The Lithanode and General Electric Co., Lim., and J. T. Niblett. Improvements in plates or elements for secondary electric batteries. May 16.

13,274. C. Rousseau. Improvements in the manufacture of plates for electric accumulators. May 16.

13,339. H. H. Lake.—From A. C. Girard and E. A. G. Street. An improved manufacture of carbon for electrical purposes. May 9.

13,568. C. T. J. Vantou. An improved dry electrolytical process for the production of an alloy of lead and sodium or potassium. May 16.

22,912. E. H. Wheeler. Improvements in electrodes and cells for secondary batteries or accumulators. April 25.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

7519. F. Boek and E. Wipperf. Improved soap. April 16.

7520. F. Boek and E. Wipperf. Improved soap. April 16.

7548. J. Y. Johnson.—From L. Rivière, France. Improvements in the manufacture and use of fatty acids. April 16.

7846. W. B. Leachman. Improvements in or connected with apparatus for purifying or clarifying oils, fats, and other similar materials. April 20.

8022. J. H. Iredale and J. W. W. Huddleston. Improvements in soap. April 23.

8399. A. G. Spilbury. Improvements in the manufacture of paraffin wax. April 27.

8669. J. F. Bennett, A. Firth, and F. H. Firth. Improvements in lubricants and method of applying same for gas engines, oil engines, and other cylinders. May 2.

8676. W. H. Horton. An improvement in what is commonly called dry soap or soap powder. Complete Specification. May 2.

8965. B. Weigel and J. Hands. Improvements in the manufacture of detergents. May 5.

9179. A. Wendtland. An improved process for removing the green colour from paraffin, vaseline, and lubricating oils, which have had that colour imparted to them by bodies containing oxygen. Complete Specification. May 9.

9200. M. Zingler and W. Chattaway. See Class XV.

9364. D. Young.—From J. Marini, Italy. An improved lubricant, chiefly designed for use on the collectors of dynamo electric machines. May 11.

### COMPLETE SPECIFICATION ACCEPTED.

1894.

5821. F. J. Machalski. Improvements in apparatus for extracting fat and glue. May 9.

## XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

### APPLICATIONS.

5856a. H. P. Scott. Improvements in anti-corrosive compositions or paints for coating iron, steel, or metal structures. Filed April 26, date claimed 21 March 1894.

5856b. H. P. Scott. Improvements in anti-corrosive compositions or paints applicable for coating iron, steel, or other metal surfaces exposed to the action of petroleum, turpentine, or like liquors. Filed April 26, date claimed 21 March 1894.

8005. E. C. Marks. A compound for a liquid preparation for reproducing pictures from illustrated papers on writing or drawing paper in black or colours. April 23.

8112. C. W. Kriens. Improvements in the manufacture of animal charcoal. April 24.

8178. C. M. Pielsticker. Improvements in the production of copper colours. April 25.

8213. W. C. Horne. Improvements in the manufacture of zinc-white paints. April 25.

8297. A. S. Caine and H. Gillmer.—From C. L. Bartlett, United States. An improved paint compound or pigment. April 26.

8298. A. S. Caine and H. Gillmer.—From C. L. Bartlett, United States. An improved paint compound or pigment. April 26.

8806. G. W. Thomas. Improvements in compositions for use in waterproofing absorbent matters and materials and for preserving metals from oxidation. May 3.

9194. W. H. Hyatt. Improvements in the manufacture of paint. May 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

9930. J. Renison. A new material for making varnish and the like. May 9.

12,791. E. Edwards. — From J. W. Overton. An improved paint. May 16.

1894.

1301. J. W. Blake and S. J. Blake. Improvements in compositions or paints for preserving ships' bottoms and other structures. May 9.

#### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

##### APPLICATIONS.

7650. F. G. Armfield. A new and improved process for staining any kinds of tanned leather in a variety of shades of colour on each single skin. April 17.

8894. J. Rees. Improvements in the treatment of gelatine and the manufacture of articles therefrom. May 4.

9090. R. Combret. Improvements in the manufacture of substances suitable for finishing, polishing, preserving, or otherwise treating leather skins, hides, and the like. May 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

12,849. C. Heinzerling. Improvements in tanning. May 2.

1894.

5821. F. J. Machalski. See Class XII.

#### XV.—AGRICULTURE AND MANURES.

##### APPLICATIONS.

8887. F. W. Saatmann. Improvements in the manufacture of superphosphates. May 4.

9200. M. Ziegler and W. Chattaway. Improvement of manufacturing guano from the refuse of fish and other animal matter, and the extraction of oil or fat therefrom. May 9.

#### COMPLETE SPECIFICATION ACCEPTED.

1893.

11,804. H. E. Newton.—From C. Seybold and F. Heeder. Improvements in the manufacture of manures and new processes for obtaining the same. April 25.

#### XVI.—SUGARS, STARCHES, GUMS, Etc.

##### APPLICATIONS.

8463. B. Laeh and H. Benies. Process for purifying and decolourising saccharine juices and solutions. April 28.

9054. H. H. Lake.—From A. L. Todesco, France. Improvements relating to the manufacture of sugar, syrups, alcohol, and beer. May 7.

9436. E. Hubner. Improvements in the manufacture of white sugar and the like from molasses. Complete Specification. May 12.

#### XVII.—BREWING, WINES, SPIRITS, Etc.

##### APPLICATIONS.

8212. F. W. M. Karsten.—From E. Karsten, Germany. Improved means or method of treating barley and other grain for its conversion to malt for brewing, distilling, or other purpose, and in the construction of apparatus connected therewith. April 25.

9054. H. H. Lake.—From A. L. Todesco, France. See Class XVI.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

10,914. E. O. Greening and E. W. Greening. An improved method of utilising spent hops for food and litter. May 9.

11,936. F. R. Stone. An aerator and rouser for wort or liquor. May 9.

23,998. C. Zimmer. Improvements in the process and apparatus used in brewing. May 9.

1894.

3642. J. C. Pennington. Improved process for the manufacture of beer. May 2.

#### XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

##### APPLICATIONS.

##### A.—Chemistry of Foods.

7543. E. O. Tatlin. An improved composition for use as food, and method of preparing the same. Complete Specification. April 16.

7612. R. G. Nash. Improvements in or relating to the "aeration of milk." April 17.

8744. F. Goracci and A. Anselmi. A new or improved compound for use as an ingredient for soup or other food and method of manufacturing the same. May 2.

8814. A. C. Sterry. Improvements in the preservation of eggs. May 3.

##### B.—Sanitary Chemistry.

7574. G. C. Purvis. New or improved method of sewage purification. April 17.

7656. F. W. Stoddart. Improved apparatus for the treatment of sewage and similar liquids. April 18.

7992. R. Schneider. Improvements in and apparatus for the utilisation of refuse. April 23.

8117. J. Posno. See Class II.

9338. O. Schmidt. An improved process for purifying sewage and waste water of a putrescible character. May 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

##### A.—Chemistry of Foods.

1893.

6662. J. Miles. Improvements in the manufacture from vegetable substances of products suitable for use as cattle food, for making boiler compositions or fluids, and for other purposes. May 2.

15,714 J. Y. Johnson.—From C. F. Boehringer and Soehne. Improvements in the manufacture of compounds for alimentary and medicinal purposes. May 16.

*B.—Sanitary Chemistry.*

1894.

1169. A. J. Boulton.—From F. S. Salberg and M. Neumann. Improvements in or relating to the disinfection of house or other refuse and apparatus therefor. May 16.

*C.—Disinfectants.*

1893.

9359. G. Whalley. A new compound or mixture for purifying sewage and foul water or liquid. May 2.

**XIX.—PAPER, PASTEBOARD, Etc.**

*APPLICATION.*

8766. J. P. Cornett. Improvements in or relating to the manufacture of paper. May 3.

*COMPLETE SPECIFICATION ACCEPTED.*

1893.

13,175. G. Sinclair. Improvements in or connected with boilers for boiling or chemically treating and for washing esparto grass and other grasses, straw, wood, rags, and other fibrous materials for paper-making. May 9.

**XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.**

*COMPLETE SPECIFICATIONS ACCEPTED.*

1893.

16,589. B. Willeox.—From C. F. Boehringer and Soehne. Process for obtaining an iron albumen derivative from animal organs. May 9.

1894.

4018. W. Mallmann. An improved manufacture of artificial musk. April 25.

6190. F. Krafft and A. Roos. Manufacture of esters, phenol, and other ethers by means of aromatic sulphonic acids. May 16.

**XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.**

*APPLICATIONS.*

7973. J. M. Gillies, R. M. Inglis, E. E. F. d'Albi, and W. C. Nixon. Improvements in colour photography. April 23.

8016. B. J. Edwards. Improvements in the manufacture of photographic films and plates, and in apparatus for use therein. April 23.

*COMPLETE SPECIFICATIONS ACCEPTED.*

1893.

8956. C. E. Pettritt. Improvements in the manufacture of sensitive plates and films for photographic purposes. May 2.

10,685. W. Jones and H. Jones. Improvements in or connected with the production of photographs on slate. May 2.

11,796. F. Steinberg. An improvement in photography. April 25.

11,872. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Improvements in photographic developers. April 25.

20,342. F. J. M. Gerland, W. C. Hesse, and M. Levy. Improvements in half-tone negatives for photo-mechanical processes. April 25.

21,379. A. G. Adamson. Improvements in the application of electric light for photographic purposes and apparatus therefor. May 2.

**XXII.—EXPLOSIVES, MATCHES, Etc.**

*APPLICATIONS.*

7944. L. de Stein and J. Joscht. Improvements in the manufacture of matches and of rubbing surfaces therefor. April 21.

8805. G. W. Thomas. Improvements in matches, fuses, and the like. May 3.

9017. H. J. P. Sprengel. Improvements in the preparation of explosive compounds. May 7.

9149. T. Tallyn. Railway detonating signal and apparatus. May 9.

*COMPLETE SPECIFICATIONS ACCEPTED.*

1893.

9688. J. McNab and J. Dickson. Improvements in gun-powder cartridges for mining and blasting, and the apparatus employed therein. May 16.

1894.

1846. G. E. Cassel and D. Kempe. An improved process of preparing pine or analogous wood for the manufacture of matches. May 9.

4626. A. Maurette. An explosive composition. May 2.

5939. H. Priester. An improved compound for use in the manufacture of matches. April 25.

*PATENT UNCLASSIFIABLE.*

*COMPLETE SPECIFICATION ACCEPTED.*

1893.

10,979. F. M. Grumbacher. Improvements in and relating to the treatment of vegetable substances and the like for preserving and vulcanising the same and for obtaining products of distillation therefrom. April 25.

# THE JOURNAL OF THE Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 6.—Vol. XIII.]

JUNE 30, 1894.

[Non-Members 30/- per annum; Members  
2/- per Set of extra or back numbers;  
Single Copies (Members only) 2/6.

### The Society of Chemical Industry.

#### Past Presidents:

Sir H. E. Roseoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, Bart., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.
Sir John Evans, K.C.B., F.R.S.	1892—1893.

### COUNCIL FOR YEAR ENDING JULY, 1894.

*President:* E. C. C. Stanford.

#### Vice-Presidents:

Sir F. A. Abel, Bart., F.R.S.	Dr. W. H. Perkin, F.R.S.
Horace T. Brown, F.R.S.	Prof. J. Emerson Reynolds,
H. Brunner.	M.D., D.Sc., F.R.S.
Wm. Crowder.	John Spiller.
Sir John Evans, K.C.B., F.R.S.	Prof. T. E. Thorpe, F.R.S.
Dr. F. Hunter.	Sir John Turney.
E. K. Muspratt.	

#### Ordinary Members of Council:

R. Forbes Carpenter.	C. C. Hutchinson.
Prof. Frank Clowes, D.Sc.	John Pattinson.
Dr. C. Dreyfus.	Manning Prentice.
Thos. Fairley.	Boverton Redwood.
C. A. Fircusitt.	A. Gordon Salamon.
Prof. G. G. Henderson, D.Sc.	T. Tyrer.

With the Chairmen and Secretaries of Sections.

#### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, B.

#### Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

*General Secretary:* Charles G. Cresswell.

*Offices:* Palace Chambers, 9, Bridge Street, Westminster, S.W.

### THE JOURNAL.

#### Publication Committee:

F. Machenhauer	III., IV., VI.		XI., XII.
W. G. McMillan	X., XI., XIV., XXII.		

### NOTICES.

In accordance with the provisions of Rule 18 of the By-Laws, notice is hereby given that those Members of Council whose names are placed in italics in the annexed list, will retire from their respective offices at the forthcoming Annual General Meeting.

Dr. T. E. Thorpe, F.R.S., has been nominated to the office of President; and Mr. E. C. C. Stanford has been nominated Vice-President under Rule 11.

Mr. John Calderwood, Dr. C. Dreyfus, Dr. A. Dupré, F.R.S., and Prof. W. A. Tilden, F.R.S., have been nominated Vice-Presidents under Rule 8; and Mr. Wm. Thorp has been nominated an Ordinary Member of Council under Rule 17, in the place of Dr. C. Dreyfus, nominated a Vice-President.

Mr. C. A. Leysitt has been nominated an Ordinary Member of Council under Rule 24, and the Treasurer and Foreign Secretary have been nominated for re-election to their respective offices.

Mr. David Howard, Mr. George N. Stoker, and Mr. Frank Wilson have been nominated under Rule 18, and Prof. A. K. Huntington has been nominated under Rule 19, to fill four vacancies among the Ordinary Members of Council.

A Ballot List and Member's Ticket are enclosed herewith.

#### ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Edinburgh on the 17th, 18th, and 20th July next. The following is a synopsis of the arrangements:—

##### PROGRAMME.

*Wednesday, July 18th.*

9.30 a.m. COUNCIL MEETING—Queen Street Hall.

A. 10.0 a.m. GENERAL MEETING—Queen Street Hall.

##### BUSINESS:

1. Reports of Council and Treasurer.

2. Election of Office-bearers.

3. Presidential Address.

4. Miscellaneous Business.

5. Place of next Annual Meeting.

12.0 noon. ALTERNATIVE EXCURSIONS.

B. Coaches will start from the Waterloo Hotel for Rosslyn Chapel, thence *via* Hawthornden to Dalkeith Palace. By the kind permission of His Grace the Duke of Buccleuch, Dalkeith Palace and Grounds will be open for the Society's inspection.  
(Ticket, 2s.)

C. Train from Waverley Station for Penicuik, where the following paper mills will be visited:—

Messrs. Alex. Cowan and Sons, Lim., Valleyfield—Bag and Esparto.

Messrs. James Brown and Co., Eskmills—Esparto and Remedial Measures.

(Ticket, 1s. 6d.)

D. WALKS IN OLD EDINBURGH.—Baillie Dunlop and Messrs. Davidson and Ross have kindly consented to conduct small parties of Members to places of architectural and antiquarian interest in Edinburgh. Proposed excursions will be posted from time to time in the offices at headquarters.

E. 4.30 p.m. GARDEN PARTY, by invitation of Sir JAMES A. RUSSELL, Bt., the Honourable the Lord Provost of Edinburgh, at his residence, Woodville, Canaan Lane.

F. 8.30 p.m. Reception and Conversazione, by invitation of the Honourable the Lord Provost, Magistrates, and Council of Edinburgh, in the Museum of Science and Art.

*Thursday, July 19th.*

Excursions to the following groups of works have been arranged:—

*Note.*—As the time available for the inspection of these works extends only from 9 a.m. till 1 p.m., it will not be possible for any party to visit more than one group from 9.0 to M. (Tickets for each group, 1s.)

G. Floor Cloth and Linoleum Manufacture.—Messrs. John Barry, Oslere, and Co., Lim., Kirkcaldy.

H. Printing, Colour Printing, and Bookbinding.—Messrs. Thomas Nelson and Sons, Parkside Works, Edinburgh.

Machinery Manufacture.—Messrs. Bertrams, Limited, St. Katharine's Works, Sciennes, Edinburgh.

Brewing.—Messrs. James and Thomas Usher, Park Brewery, St. Leonard's Hill, Edinburgh.

I. Brewing.—Messrs. Wm. McEwan and Co., Limited, Fountain Bridge, Edinburgh.

Distilling.—The North British Distillery Co., Limited, Gorgie Road, Edinburgh.

J. Collieries, Brick and Fireclay Manufacture.—The Lothian Coal Co., Lim., Rosewell.

K. Paraffin Oil and Shale Distillation.—The Broxburn Oil Co., Lim., Broxburn.

L. Flint Glass Manufacture.—Messrs. John Ford and Co., Holyrood Glass Works, Edinburgh.

Brewing.—Messrs. William Younger and Co., Lim., Abbey Brewery, Edinburgh.

Gas Manufacture.—Edinburgh Gas Works, Canon-gate, Edinburgh.

M. Ornamental Glass Manufacture.—Mr. A. D. Jenkinson, Abbeyhill, Edinburgh.

Disposal of Refuse.—Edinburgh Refuse Destructor, Powderhall, Edinburgh.

Shipbuilding.—Messrs. Ramage and Ferguson, Lim., Leith.

Docks.—Leith Docks. Peter Whyte, Esq., C.E., Superintendent.

N. 1.0 p.m. A steamer will leave the West Pier, Leith, for the Forth Bridge, sailing thence to Granton, where, by invitation of Messrs. A. B. Fleming and Co., a Garden Party will be held at Royston. The Society will have an opportunity of inspecting the manufacture of Lamp Black, Printing Inks, and Solidified Oils, at Caroline Park. The Marine Station will be open for inspection. The Members will return to Edinburgh by special train at 6 p.m.  
(Ticket, 2s. 6d.)

O. 7.30 p.m. The Annual Dinner will take place at the Waterloo Hotel, Edinburgh. Ticket (including light wines), 10s. 6d.

*Friday, July 20th.*

Excursions will leave the Waverley Station for—

P. Aberdeen, crossing the Forth and Tay Bridges.  
(Ticket, 10s.)

Q. Perth and St. Andrews. The Members will be conveyed, *via* the Forth Bridge, to St. Andrews, thence, *via* the Tay Bridge, to Dundee and by Steamer to Perth; returning from Perth by rail. (Ticket, 10s.)

R. 9.0 p.m.—Smoking Concert in the Waterloo Hotel.

The Headquarters of the Society during the Meeting will be in the Waterloo Hotel, where an Inquiry and Information Bureau will be open on the 17th, 18th, 19th, and 20th of July, for the issue of tickets and full particulars relating to the various items upon the programme. Payment for excursion tickets, &c., will only be received at the Treasurer's Office, Waterloo Hotel. Ladies will be able to take part in nearly all the above excursions and parties.

#### BANKERS' ORDERS.

For the convenience of Members, the Treasurer has arranged with the Bankers of the Society that they shall collect subscriptions from Bankers in town and country; and Members, who have not already done so, are invited to fill up and sign the Banker's Order enclosed with the December number of the Journal, which should then be sent to the Honorary Treasurer, Mr. E. Rider Cook, East London Soap Works, Bow, E.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. Fyfe and Spottiswood, the Society's printers and publishers, to whom all communications respecting them should be addressed.

#### CHANGES OF ADDRESS.

Allen, R. L., 10 Roscleigh; Heaton House, Heaton Chapel, Stockport.

Annandale, C. J. R., 10 Peckham; The Briary, Shotley Bridge, co. Durham.

Batterfield, J. C., 10 Westminster; Almaraz del Pan, Zamora, Spain.

Fletcher, R. Jacques, 10 Bromley; 419, King Street, Melbourne, Victoria.

Goodwin, C. C., 10 Old Trafford; The White House, St. John's Road, Bowdon, Cheshire.

Hetherington, Dr. A. E., 10 Sandown Lane; 24, Church Road, Wavertree, Liverpool.

Johnson, E. E., 10 Manchester; Warren Hill House, Loughton, Essex.

#### CHANGES OF ADDRESS REQUIRED.

Scott, Chas. K., 10 Caixa, Pernambuco, Brazil.

Wellington, Stephen N., 10 The Gas Works, Norwich.

#### LIST OF MEMBERS ELECTED 22nd JUNE 1894.

Aldrick, E. J., 10 26; 27, Alpha Road, West Ferry Road, Millwall, E.

Booth, Robt., 110, Cannon Street, London, E.C., engineer.

Burtherton, E. A., 10 Hkley; Commercial Buildings, Leeds.

Brunner, Henry Bertram, Winnington Old Hall, Northwich, chemist and electrician.

Clementson, Henry, Columbus Distilling Co., Greenpoint Avenue, Brooklyn, N.Y., U.S.A., distiller.

Fulton, Robt., jun., Nobel's Works, Stevenston, Ayrshire, N.B., chemist.

Georgi, Carl, 77, John Street, New York City, U.S.A., aniline dye importer.

Henderson, Norman M., Broxburn Lodge, Broxburn, N.B., oil works manager.

Henshaw, Sam, Staffordshire Chemical Co., Lim., Tunstall, Stoke-on-Trent, manager.

Hopkins, Erastus, 10 Providence; 12, Linden Street, Worcester, Mass., U.S.A.

Horrocks, W. A., 10 Salford; 5, Egerton Avenue, Urmston, near Manchester.

Howden, Wm., 5, Loekharton Terrace, Slateford, N.B., engineer's agent.

Hurry, E. H., c/o Atlas Cement Co., 143, Liberty Street, New York, U.S.A., engineer.

Ibison, Geo., 6, Clarence Road, Croydon, paint works manager.

Kennedy, Wm., 28, Royal Exchange Square, Glasgow, Director—Broxburn Oil Co.

Lungwitz, Emil E., 159, Front Street, New York City, U.S.A., chemist.

Macfarlane, W. D., c/o Canada Paper Co., Craig Street, Montreal, Canada, paper manufacturer.

Mole, Herb. B., Shepton Mallet, Somerset, brewer.

Ormerod, John, Croft Head, Littleboro', near Manchester, tanner.

Pearce, Jas. S., Clements, Snaresbrook, Essex, chemical manufacturer.

Platten, Frank, c/o Elliott's Metal Co., Lim., Selly Oak, Birmingham, metallurgical chemist.

Ray, Wm., 10 Manchester; 23, Railway Road, Urmston, near Manchester.

Richardson, Jas. C., 19, Claremont Square, London, N., electro-chemical engineer.

Robinson, Jno., 10 Widnes; 9, Stanley Villas, Greenway Road, Runcorn.

Robson, Jas., 204, George Street, Glasgow, chemist.

Segundo, E. C. de, 28, Victoria Street, Westminster, S.W., chemical engineer.

Sexton, Prof. A. H., 10 Bath Street; 204, George Street, Glasgow.

Watson, Chas. E., Manchester Alum Works, Manchester, chemical assistant.

Whitehead, Wm. T., Magog, Prov. Ontario, Canada.

## London Section.

THE CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE, W.

*Chairman:* Wm. Thorp.

*Vice-Chairman:* W. Crocker.

The names in italics are those of Members of Committee who retire at the end of the current session.

The following have been elected to fill the vacancies, and will take office in July next:—*Chairman:* R. E. R. Newlands. *Committee:* E. Grant Hoover, H. de Meuthal, E. O'Neill, S. Rideal, A. Shearer, and Wm. Thorp.

SESSION 1893-94.

*Meeting held Monday, May 21st, 1894.*

MR. WILLIAM THORP IN THE CHAIR.

## THE MANUFACTURE OF SMOKELESS POWDER.

BY OSCAR GUTMANN, ASSOC. M. INST. C.E., F.I.C.

The general interest created by the appearance of the so-called smokeless powder for military use, and their adoption by nearly every army in the world, together with the comparative ignorance in which the civilian public finds itself with regard to the nature and production of these powders, made me think that a brief summary of the most striking peculiarities of this rapidly increasing industry would be of interest.

Most of you will be aware that in 1888, the world was first startled by the appearance of newspaper reports about a new and smokeless powder invented by a chemist of the French Government, and that very soon after this the German Army had a similar one. It has since been stated that the first experiments in connexion with the discovery of smokeless powders were made in 1881, by Mr. Vieille, the well-known chemist of the French Government Gunpowder Factories. What this powder at that stage was is not quite clear, but it is not improbable that it consisted of a mixture of collodion cotton and picric acid, similar to the original basis for the much talked of melinite. This composition, however, seems to have been abandoned after a short period, and that kind of smokeless powder which is now very largely used in other countries as well as in France, to have been adopted.

In 1889, Alfred Nobel took out a patent for the manufacture of "Ballistite," which is an ingenious modification of his blasting gelatine. This, and the above-mentioned French powder are the two types upon which most of modern smokeless powders are based.

The first approach to a powder giving no smoke on combustion, and which at the same time, was not composed of the usual saltpetre, sulphur, and charcoal mixture, was, apart from the gun cotton used over 30 years ago, the Schultze powder, which has been used as a sporting powder in this country for more than 20 years, and which consisted of nitrated wood, prepared by the treatment of wood

with nitric acid, mixed with saltpetre or a similar substance. Although this powder has been brought to great perfection for sporting purposes, it has failed to be practicable for military use, since it can hardly be such a uniform material as is required for this purpose.

A much nearer approach to the modern smokeless powders, and, in fact, in some way indicative of them, was the E.C. powder, invented by Mr. Walter F. Reid, and patented in 1882 by Messrs. Reid and Johnson. Generally speaking, Reid formed grains of nitrocellulose by putting powdered nitro cotton into a barrel, sprinkling it over with water and revolving the barrel, whereby, through agglomeration, grains of various sizes were formed. These were dried and then moistened with ether-alcohol, which had the effect of gelatinizing the surface of the grains. A small addition of aurine gave the powder an orange colour. After being again dried, the grains were then put through a sieve in order to separate them, since they adhered slightly to each other through the gelatinizing process.

In a similar way Max. von Forster made cubical gun cotton powder by cutting cubes out of compressed gun cotton and dipping them into a solution of acetic ether which coated them externally with a thin skin of collodion. This was only used for filling shells. Later on Messrs. Judson and Horland made a smokeless powder called the J.H. powder, by a process similar to the E.C. powder process, the only difference being that the gun cotton grains were treated with a solution of camphor in benzoline, which on being evaporated, left some camphor behind. This powder did not remain long in the market.

It is a pity that Mr. Reid stopped at this stage of the manufacture, because he was very near making that class of smokeless powders which are now known as pure gun cotton powders; but in extenuation it may be said that at that time, the want of such a powder had not been clearly expressed, since there was then neither rifle nor projectile in existence which would have been suitable for the use of powders whose pressures and velocities are so much higher than those of the ordinary black powder.

It is due to the success of the long continued experiments of two Swiss experts, Major Rubin and Professor Hebler, who have advocated for more than 10 years the adoption of the small calibre rifle, that powder manufacturers have been forced to find powders suitable for the use of such weapons.

I remember very well how in the beginning of 1886, Professor Hebler showed me an experimental cartridge case made for his small calibre rifle, and asked me whether I could give him a pellet of compressed gun cotton which could be loaded into such a cartridge case, and which would be likely to give to his long cylindrical projectile the required velocity. I then pointed out to him that such a charge would be impossible on account of the sudden combustion and the very high pressure it would develop, and I offered to make him a small piece of blasting gelatine which would burn more in layers, and, therefore, probably suit his purpose better. The very suggestion of using blasting gelatine in a rifle was so much against all recognised ideas, that the matter was not further proceeded with; but after all, that rather hazardous suggestion of mine has turned out to be an idea in the right direction, although I had no further part in its development.

Modern smokeless powders can be divided into three classes. First those in which only gun cotton is used, whether it be the so-called insoluble or the so-called soluble variety. Secondly, those in which nitroglycerin is used in connection with soluble or insoluble nitrocellulose. Thirdly, those which contain nitrocellulose in connection with a nitro-derivative of some aromatic hydrocarbon.

There have also been devised some other smokeless powders containing nitrocellulose in connection with oxygen carriers and also some which consist of merely mechanical mixtures of oxygen carriers and carbonaceous matters, but none of them have yet found favour for service use.

I will just briefly indicate the composition of those smokeless powders which have hitherto been devised. In the first place, come the pure nitrocellulose powders, where the nitrocellulose is simply dissolved in some solvent and then made into flakes or grains. Such powders are the

French B. powders, the German smokeless powder, the Wettstein, the Wal-rode, von Forster's, and various others. The French Government, von Forster, and a few others are using a mixture of ether and alcohol as a solvent; the German factories, acetone. The nitrocellulose used is as a rule guncotton, although in some cases, wood nitrocellulose has been tried.

With the pure nitrocellulose powders can be classed the E.C. and the J.B. powders. The E.C. powder, now sold as No. 2, contains some camphor and is soaked throughout in ether-alcohol, whereby a harder grain results. To the second class belong powders made of nitroglycerin and nitrocellulose. There is first of all the Ballistite of Mr. Alfred Nobel, consisting of equal parts of nitroglycerin and collodion cotton, with an addition of 1 to 2 per cent. of aniline or diphenylamine. This Ballistite has with some modifications, been adopted in Italy, Austria, and for some guns in Germany. In Italy when made into cords, it is called Filite. To the same class belongs the Cordite, adopted by the British Government. This consists of 58 parts of nitroglycerin, 37 parts of the highest nitrated guncotton, and 5 parts of vaseline, which ingredients are dissolved in 19.2 parts of acetone.

Curtis and André made a powder consisting of 44 parts of tri-nitrocellulose, 12 parts of di-nitrocellulose, and 40 parts of nitroglycerin, with an addition of solid paraffin and shellac solution, which is formed into grains by means of a mixture of ether-alcohol. This powder is sold under the name of Amherite.

M. E. Leonard, of Manchester, in the United States, makes a powder of 150 parts of nitroglycerine, 50 parts of guncotton, 10 parts of lycopodium, and 4 parts of powdered urea crystals dissolved in acetone.

To the third class, namely, those containing nitrated aromatic hydrocarbons, belong the following powders:—The Indurite of Professor Charles Monroe, which is made from insoluble nitrocellulose and nitrobenzin. The Dupont powder of the Dupont Powder Company at Wilmington, U.S.A., which also consists of nitrocellulose and nitrobenzin granulated by a peculiar process.

There are also a large number of powders brought out by the Smokeless Powder Company of Warwick, under the name of Rifleite, S.S., S.P., S.K., S.V., and S.B. They are not patented and their composition is kept secret, but from information received from various sources, I believe that the Rifleite consists of soluble wood nitrocellulose dissolved in acetone and mixed with nitrobenzin and saltpetre, and granulated in a similar manner as the E.C. powder.

A very remarkable powder of this class is made by Hermann Guttler of Reichenstein, in Germany, which is made by dissolving nitrated wood cellulose in molten di-nitrotolual.

To the miscellaneous class of smokeless powders belong really only two powders which are both sold by the French Government for sporting purposes. One kind is called Poudre Pyroxylée, and it is composed as follows:—

Soluble guncotton	-	28 parts.
Insoluble guncotton	-	37 parts.
Barum nitrate	-	29 parts.
Potassium nitrate	-	6 parts.

Ether is used as a solvent with this powder. The other more recent one which has substituted for the Poudre Pyroxylée, is the so-called J. Powder. This is due to the Engineer Brunau, and consists of 83 parts of guncotton, and 17 parts of ammonium bichromate. The Nobel Company of Austria also proposed to make a smokeless powder consisting of 70 to 99 parts of nitro-starch, and 30 to 1 part of di-nitro-benzine, but it does not appear to have been adopted yet.

There were also various other powders proposed, such as that of Kaliwoda von Falkenstein, and that of Koli and others, but these propositions have apparently been made by people not sufficiently conversant with the requirements of a good service powder and they need not therefore be considered here.

One of the most important conditions in the preparation of smokeless powder, is the proper selection of prime materials. I do not intend to give an opinion as to the

relative value of the various powders and consequently of the constituents. Generally nitrocellulose has been selected as a chief ingredient, and from the many nitrocelluloses available, the nitrocotton, or guncotton, has been most favoured. There are besides the nitrocellulose, many nitro compounds known, which possess explosive properties, and give off no fumes, or very few, in burning, but nitrocellulose seems to have been selected, because it can be readily dissolved, and is well known, a solution can be mixed much more easily than a mechanical compound, and also because, after the solvent is evaporated, the nitrocellulose remaining can be shaped into various forms by easy mechanical means and without any danger.

The wood used for making nitrated wood cellulose was formerly, like the Scholtze powder, cut up into thin squares. In modern smokeless powders, the wood pulp from the sulphite cellulose, or soda processes of cellulose manufacture, such as is supplied for paper making has been used. This kind of cellulose is generally supplied from the factories in thin sheets, which are not very porous, have rather a glazed surface, and would have to be again reduced to pulp before it could be nitrated. A more convenient form, and at the same time, a very pure kind of cellulose has been made by the chemical factory of Waldhof. This cellulose resembles tissue paper, the difference being, that it is of looser structure, more like gauze, very porous and can be easily torn into small pieces by hand, so that it can be used direct for nitration. The wood cellulose has not yet been adopted by many factories for the reason that it does not seem to give such a tough powder as guncotton.

I believe that it is unnecessary nowadays to refer at length to the well known differences between soluble and insoluble guncotton. Suffice it to say that it is generally recognised that the term soluble nitrocellulose means that kind of nitrocellulose which is soluble in ether-alcohol, but that it is not always of the same composition, since the amount of nitrogen contained in the soluble nitrocellulose may vary up to 12.78 per cent., and also the insoluble nitrocellulose may contain from 12.78 up to 14.14 per cent. of nitrogen. This does not mean that the soluble nitrocellulose contains an admixture of what is known as hexa-, or insoluble, nitrocellulose. It may be a mixture of various kinds of soluble nitrocellulose, that is to say, of intermediate stages of nitration between mono and penta-nitrocellulose, but the whole of it must be soluble in ether-alcohol. At the same time, it is necessary that the nitrocellulose should comply with certain requirements laid down to adapt the powder made therefrom for the special purposes it is intended for.

Thus, for instance, certain powders will be made of a soluble nitrocellulose containing less nitrogen, and others from such containing the highest possible amount of nitrogen consistent with perfect solubility. As regards those powders, where only the highest or hexa-nitrocellulose enters into the composition, it is apparent to all who are acquainted with the manufacture of nitrocellulose, that it has been hitherto impossible to obtain nitrocellulose containing 14.14 per cent. of nitrogen, that is consisting entirely of hexa-nitrocellulose. Generally the guncotton, which is the most used form of hexa-nitrocellulose, contains about 12 per cent. soluble nitrocotton, but guncotton containing only 2 per cent. has been made by me on a large scale. In using hexa-nitrocellulose, one has therefore to be careful to regulate the amount of soluble nitrocellulose, which can be done either by blending or by using special means during the manufacture.

It was for sometime known and recently proved by Messrs. Nobel and Macnab, that by treatment at a temperature much below the freezing point of mercury, the so called insoluble nitrocellulose is soluble in ether-alcohol, but these are conditions which are only obtained quite exceptionally. It has also been found by Professor Odling, that by making special mixtures of nitric and sulphuric acids, it is quite possible to make two kinds of guncotton, both containing about the same amount of nitrogen, yet the one is soluble and the other insoluble in ether-alcohol. This has no other bearing upon the practical manufacture, than that of showing the manufacturer how to avoid obtaining such results, which would be contrary to his

intentions. What is generally aimed at, and what is nowadays quite possible, is to obtain nitrocellulose containing a definite amount of nitrogen and a suitable amount of solubility or insolubility.

Most military powders contain only the highest nitrocellulose, generally dissolved in acetie ether or acetone. In sporting powders, where less rapid action is desirable, soluble nitrocellulose is used, sometimes dissolved in a mixture of ether and alcohol.

Of the nitroglycerine used for the manufacture of smokeless powder, very little need be said, since nowadays there is no difficulty in producing a perfectly stable and in every respect suitable article. Of course it is not so easy as it would seem from the indication given in text books. It can only be done in factories conducted on sound scientific principles, and having large experience at their disposal.

A very important feature as to the final composition of the powder is the solvent used. Although its complete evaporation is almost invariably aimed at, yet small traces of it and especially such impurities as exist in the solvent, will remain in the powder. The nature of the solvent bears largely upon the structure and appearance of the dough prepared, and consequently, the finished powder may have a different density and a different surface, and thereby a different rate of combustion.

It is known that ether by absorption of moisture, becomes acid in time, and although on evaporation, the powder does not seem to be technically acid, yet if proper care is not taken, it may not stand the heat test as well as it ought to. Acetone is a comparatively new solvent, and of that made on a commercial scale, very little was known. For use with smokeless powders, it has to comply with a severe specification. A good serviceable acetone should be quite clear and miscible in all proportions with distilled water, without any precipitate forming. It should not have more than 0.005 per cent. of acidity, nor more than 0.1 per cent. of aldehyde. With Krammer's iometric test (transformation into iodoform by an excess of iodine solution in the presence of soda solution) it should show at least 98 per cent. of pure acetone and when treated with a 0.1 per cent. solution of permanganate of potash, it should retain its coloration for more than two minutes.

I have here a sample of acetone such as is used in very large quantities for military purposes. It has a specific gravity of 0.7965. 98 per cent. of this acetone distils over between 56.2° and 56.4° C. It stands the permanganate test for nine minutes and shows 0.00225 per cent. of acidity. An addition of alcohol to acetone has been tried and it seems to make the powder burn a little slower, but this can also be accomplished in other ways.

The nitrocellulose is of course dried at a temperature not exceeding 40° C. This is usually done in specially constructed drying houses to which I have referred in a former paper before this Society. I only wish to mention this on account of a peculiar process which was used in Austria as early as 1891 at least, but which was patented in this country in 1892. It consists in what they call the alcoholisation of the nitrocellulose, namely, adding alcohol of high percentage to the wet nitrocellulose, diluting thereby the alcohol, and then evaporating the diluted spirit. Since the boiling points of dissolved alcohol and moderately diluted alcohol are very nearly the same, and since both are very much lower than the boiling point of water, it is clear that the removal of the moisture is done much more rapidly in this way. In order to utilize the alcohol more fully, one can, as it has been suggested in France, use the alcohol in separate stages, that is to say, using first, diluted alcohol from former treatment, and after evaporating it, using the stronger one, which would have to deal with a smaller amount of water, and so on three or four times, whereby a considerable saving in alcohol would be effected.

I believe that in France, flat ebonite vessels were originally used, in which the guncotton was spread out in a thin layer, and the solvent poured over it. These vessels were then put under glass covers and allowed to stand until the solution was completed. Then a current of air heated to 55° C. was passed over it to evaporate the ether, and this was condensed in separate apparatus.

Nearly all the powders are made up by very simple processes. The solution of nitrocellulose in the solvent is effected by means of kneading machines such as are used by bakers for preparing their dough, and which have long been used in the manufacture of blasting gelatine. Those of Werner and Pfleiderer are almost exclusively used.

Fig. 1.

Their construction is shown in Fig. 1. It consists of a trough, composed of two halves of a cylinder joined together and surmounted by a square box, consequently the bottom is about the form of a *w*. In each of these cylinder segments is a shaft which carries a helical blade. The blades revolve in opposite directions, and the one makes about half the number of revolutions of the other. The blades very nearly touch the bottom of the trough, and the consequence is, that any material brought into the machine is divided into two parts, then kneaded against the bottom of the cylinders, then pushed along the blade, and by the next half revolution, turned over by the other part of the helix; and since the velocity of the two blades is different, there will be with every revolution, a different part of the dough submitted to the kneading operation.

As a rule, the mixture of smokeless powder, when once the solvent is introduced, ceases to be liable to explosion, and is only combustible, so that these kneading machines are usually made from iron only. Since guncotton has a very high absorbing power, the amount of solvent used is about weight by weight the same, but this varies according to the length of time given to the kneading operation. It is quite possible to work with a small amount of solvent provided the kneading of the mixture is prolonged sufficiently. The question as to whether it is more advisable to use a minimum amount of solvent, or to take a minimum length of time over the operation, has to be decided from economic consideration, since hitherto it has been found impossible to recover the solvent economically. When the dough leaves the machine, in which it has been kneaded from three to ten hours, it has a perfectly uniform and translucent appearance, and has about the consistency of soft india-rubber. It then undergoes a further treatment according to the form which the finished powder is ultimately to have.

Some of the pure guncotton powders, like the Walsrode, are formed into grains by placing the mixture in hot water and blowing steam into it, which causes the dough to break up and become granular. Some are pressed through dies into cords, like the Cordite, of which mention will be made later on, but as a rule, for military purposes, the dough is passed between heated rollers and rolled out into thin sheets, the solvent being simultaneously driven off by the heat from the rollers. The general principle of such rollers is shown in Fig. 2. They consist simply of a pair of hollow highly polished hard cast-iron or steel rollers, the lower one of which rotates in a fixed bearing, whilst the upper one can be elevated by means of gearing actuated by a hand wheel. Two scrapers are placed against the rollers to prevent the rolled out sheet from doubling up against the rollers and being carried round by them.

The temperature maintained in these rollers depends upon the boiling point of the solvent used, but it does

not exceed, as a rule,  $60^{\circ}\text{C}$ . These rollers effect at the same time the thorough mixing and solution of any particles of nitrocellulose that may have escaped solution in the kneading operation. During the rolling there are occa-

Fig. 2.

sionally small detonations heard, which were by some attributed to the bursting of air bubbles in the sheet, but are most likely due to some particles of gun-cotton exploding by combined heat, friction, and pressure, which is proved by local burning marks. Such explosions do not spread and are harmless. When the rolling out of the dough into a thin sheet of the required thickness has been effected, it is taken to a cutting machine, which cuts it up into small squares or flakes of the required diameter. This cutting machine is shown in fig. 3. It consists of a number of circular steel knives set on a shaft at a suitable distance apart, by means of distance washers; two such shafts stand opposite each other in such a position that the knives overlap slightly. There is a comb or grating fixed between

Fig. 3.

Fig. 4.

Fig. 5.

the two sets of knives so as to take out the strip from the knife immediately it has been cut, and to prevent it being carried round and choking the cutter. By putting a sheet of powder between the two sets of knives, a number of strips are cut, which when they leave the circular cutters pass over a fixed longitudinal knife-edge, in front of which are two or four longitudinal knives, carried on a revolving shaft, which cut up the strips into flakes. The length of a flake depends upon the velocity with which the strips

pass from the knives and on the rate at which the chipping knives revolve. The velocity is regulated by means of cog-wheels, and as a rule, the chipping knife is driven direct from the belt, and the cutting knives from this. The knives used for cutting strips were originally made, as shown in Fig. 4 with a small bevelled edge, but this was found very inconvenient on account of the machine being easily choked. Nowadays, the form of the edge is generally that of a *Λ* as shown in Fig. 5, a form of knives which has long been in use for the purpose of cutting up Bristol board for playing cards.

In case the powder should have the form of cubes instead of thin flakes, the former are made by cementing together several sheets of powder. It would not do to make from the outset a thick sheet, because it would contain then a too large quantity of solvent, a great many air bubbles, and the mixture would probably not be thoroughly made. It is therefore better to conduct the whole operation by rolling out the mixture into thin sheets, and as there is a sufficient amount of the solvent left in them, cementing them into a thicker sheet by simply running several sheets together through the corresponding wider spaced rolls. Such cubes are perfectly translucent, and if cut normally to the surface, do not show the way how they are made, but if they are cut in an angle, the lines of division can be plainly seen. The powder after the rolling and cutting operations still contains a small amount of the solvent, which on account of the homogeneous and tough consistency of the powder, takes a good deal of time to entirely evaporate. It is therefore treated in drying houses, sometimes for more than a week, unless it is specially desired to retain a certain small percentage of the solvent. In very rare cases, it has been thought desirable to make round discs instead of square ones, and the machine adapted to that purpose, is similar to that used for making certain kinds of pastry, namely, passing the dough through a die and allowing a knife to revolve rapidly against the cord issuing from the die, thereby cutting it into fine discs.

With Nobel's Ballistite, which contains a mixture of nitroglycerine and soluble gun-cotton, it was originally intended to absorb the nitroglycerine by the collodion cotton in a vacuum vessel, then to press out the excess of nitroglycerine, and to then heat the remainder of the mixture in order to dissolve the collodion-cotton.

Later on, Messrs. Lundholm and Sayers devised a process by which the solution of nitroglycerine and nitrocellulose can be readily made without such complicated means. It is based upon the curious fact that, although gun-cotton containing a small amount of water is soluble only with difficulty in nitroglycerine, such gun-cotton is readily soluble when suspended with the nitroglycerine in a large quantity of water. For this purpose the nitroglycerine and collodion cotton are put into a vessel containing hot water and stirred by means of air, or steam, whereby the incorporation of nitroglycerine and collodion cotton takes place; but it is also sufficient to maintain the water at a temperature of about  $60^{\circ}$ , and to let the mixture stand for several days, stirring it from time to time. When the gelatinisation is completed the mixture is first submitted to pressure in order to remove the largest part of the water, and then formed into sheets under heated rollers, and finally cut and dried in the usual way. In Italy they form cords like those of Cordite, and call the powder Filite.

As it is known that nitroglycerine alone will not dissolve the highest nitrated cellulose by ordinary means, collodion cotton is used in the manufacture of Ballistite. Sir Frederick Abel and Professor James Dewar found that they could make a perfect combination of gun-cotton and nitroglycerine by dissolving them both in a common solvent. The peculiarity in this process is, that although one would imagine that on evaporating the solution the two constituents would separate, since the one is not soluble in the other under ordinary circumstances, yet the two remain in a perfect combination, which has quite the appearance of the solution effected in the case of nitroglycerine and collodion cotton. It has been claimed by Abel and Dewar that they are not in solution as a matter of fact, but are existing side by side.

In the manufacture of Cordite the gun-cotton and nitro-glycerine, together with a suitable amount of acetone, which is used as a solvent, are placed into the kneading machine and worked for  $3\frac{1}{2}$  hours, when the mass has a perfect

dough-like appearance. At this stage a small quantity of vaseline is added and the dough worked another  $3\frac{1}{2}$  hours, when the combination is considered to be perfect. During the kneading operation care is taken to prevent the escape

Fig. 6.

Fig. 7.

of the solvent, and by means of a water-cooling jacket the heat generated during the kneading is reduced so as to prevent the evaporation of the solvent. The dough is then brought into machines which squirt it through dies into the form of threads or cords.

One of the machines is shown in Figs. 6 and 7. It consists of a base-plate A and two columns BB, connected by a head C; between the two columns a cross-head D slides up and down. The mould E is contained in the base-plate A, and held in tight by clamps F; at the bottom of the mould E is a cover G, with a nozzle H made to correspond to the thickness of the cord required. Another mould I, which contains the dough, is put on the top of the mould E. In the cross head there is a nut K which can turn, and which is fixed into the base of the cogwheel L. Into this goes a screw M, having fixed to it, by means of a cutter, the piston N. The cogwheel is made to turn by means of an intermediate cogwheel P, 2 and a driving-wheel Q. 3. On the shaft of the cogwheel L 3 there is a long feather key N, and if, therefore, the cross head rises for some reason or the other, the whole mechanism slides up on the feather without ceasing to revolve. It will be seen, therefore, that on being rotated by the cogwheel, the nut, the screw, and with it the piston, must gradually descend into the mould and press out the mass through the nozzle in the form of a thin cord. In order to prevent the pressure in the mould becoming too great from any cause—such as the die getting blocked by any foreign matter—there is an hydraulic arrangement provided. The cross-head is screwed fast with a hydraulic piston, in which the screw can work up and down freely; this piston works in a cylinder which forms parts of the head of the press. Hydraulic pressure is applied on both sides of the piston by means of the pipes Q and R. Since the free surface of the piston is smaller on the lower part than on the upper one there is always a pressure acting on the piston corresponding to the difference of the two areas. The amount of pressure is regulated by means of the safety-valve S, and should it exceed a certain limit the water flows out through the safety-valve, and the cross-head and piston ascend, when the whole of the contents of the mould are pressed out; the lever T is caught by a tappet V. With this lever is connected another lever W, and as T is moved, the lever W either lifts or presses down, by means of a rod X, a counter weight, with the result that one driving-belt is thrown on to the loose pulley and the other on to the fast pulley, and the motion of the piston reversed; in the same way the machine can be brought to a standstill altogether.

The cord issuing from the press is reeled, in a similar manner to cotton spools, on to drums made of sheet metal stampings. A number of these reels are re-reeled on to a large drum, and several large drums on a larger one, so as to obtain a uniform blending. The cord is then brought to a machine, where it is pushed several strands at a time into the cartridge and cut off at the proper length. With Cordite of a larger diameter, the cord is cut immediately after leaving the die into lengths of about 12 inches.

In the case of Amherite, the manufacture is somewhat different. First of all, grains are formed from the nitrocellulose, probably in a similar way as it is done with the E.C. powder, and are subsequently treated with a solvent which dissolves the soluble nitrocellulose only, for instance, with sulphuric ether and alcohol. In this way, there is a kind of cement formed within the mass of insoluble guncotton, which binds the grains thoroughly together and yet leaves the guncotton unaltered. There is in this case, therefore, not only the hardening of the surface as in the case of the E.C. powder, but the formation of a kind of conglomerate throughout. This, of course, diminishes the rapidity of combustion of the powder a good deal. In order to arrive at a proper proportion of insoluble and soluble nitrocellulose, the patentees add the required proportion of soluble guncotton to the ordinary guncotton of commerce, which usually contains already about 12 per cent. of the soluble variety.

In the case of the Leonard powder, the materials are simply mixed with acetone and left standing for 12 hours in tightly closed pots, after which the solvent is evaporated, and the mass granulated in the usual way.

Professor C. E. Munroe proposes for his smokeless powder, which he calls Indurite, to use very pure guncotton, which he obtains by treating the ordinary guncotton in a kind of extracting apparatus with repeated infusions of methylic alcohol, until all the soluble nitrocellulose is eliminated. The remaining hexa-nitrocellulose is dissolved in nitrobenzin. He then rolls the mass out into sheets and cuts it into grains, and the resulting rather soft flakes are treated with hot water and steam as is the case with the Waisrode powder, whereby the grains harden externally. He calls this latter process the induration. I believe that as nitrobenzin is highly volatile at comparatively low temperatures, all that takes place in this induration, is simply a partial evaporation of nitrobenzin on the surface, which has the effect of leaving the guncotton bare and hard.

The Dupont powder, in which nitrobenzin and nitrocellulose also enter into combination, is made by a somewhat similar process to that of Lundholm and Sayers. The only difference is that a special apparatus with rotating paddles is used, whereby the mass is first made into a dough, and then on continued stirring, breaks up into grains. By admitting steam into the apparatus, the grains, which at first have a soft, putty-like appearance, become hard and consistent. When the grains are finished, they are placed in a rotating barrel, into which steam and water are admitted. This has the effect of making the grains round, and carrying away any excess of solvent.

The French Poudre Pyroxylée is produced by a rather complicated process. The materials are first mixed by hand, and then in incorporating mills for 45 minutes, where an addition of 40 per cent. of water is made. After this, they are rubbed through a sieve of about  $\frac{1}{16}$  of an inch mesh, dried up to 1 per cent. of moisture, and 65 per cent. of ether added to the mixture. The putty so obtained is rubbed through a perforated zinc sieve with holes about  $\frac{1}{16}$  of an inch diameter. The mixtures of grains and dust thus produced is revolved in a wooden drum for 45 minutes, then moistened with 50 per cent. of water and afterwards dried. The grains are sorted. Those between 1.6 and 1 mm. diameter being moistened with 15 per cent. of ether and polished in a copper drum. The powder is then again rubbed through a sieve of about  $\frac{1}{16}$ -inch mesh, and again sorted into grains between 1.6 and 1 mm. The residue is treated in a similar way in order to again get grains of suitable size, and the final powder consists of one part of grains of the original make, and two parts of those coming from the working up of the residue. The Poudre J is probably made in a similar way.

The properties of smokeless powders vary very much according to the composition, the mode of manufacture, and also according to the object for which they are to be used. For large guns, a powder is required which burns very slowly, in order that the force should be developed gradually so that the energy imparted to the projectile should reach its maximum as the projectile is just about to leave the gun. For sporting powders on the other hand, a quick combustion is desirable in order to impart to the shot sufficient penetration and little spreading, or what is called, a good pattern. At the same time, the powder should develop as small a gas pressure as possible and a very high muzzle velocity. For military purposes it is desirable that there should be as much force as possible given off by unit weight of the powder, because this enables rifles of small calibre to be used, and it also allows the soldier to carry a large number of cartridges. For sporting powder on the other hand, it is not possible to change the type of the guns in use as rapidly as it can be done by the aid of a national exchequer with Service rifles, and the sportsman prefers a powder that he can use in the same cartridge as black powder. Considering then that an average charge of black powder for a 0.500 express rifle, is about 138 grains of Curtis and Harvey's No. 6 black powder, whereas of a good smokeless powder, only 47 grains are needed, it is easy to see that with the smokeless powders, a large space of the cartridge will remain empty, although the volumetric density of the smokeless powder is much smaller than that of black powder. For sporting purposes, therefore, such a powder whose volumetric density is the smallest,

and which is consequently most likely to fill the whole of the cartridge case, possesses some advantage.

This brings forward another question which has for some time given a good deal of trouble with smokeless powders, namely, the loading of cartridges. With black powder, a slight increase of the charge meant much less than with smokeless powders. The latter are very liable to set up extraordinary pressures when the charge increases, and with some of them it has been found impossible to take more than  $1\frac{1}{2}$  times the charge for fear of bursting the gun. On account of the flaky nature of some of the powders, the ordinary machines for loading cartridges, where the powder

runs through a funnel in a measured vessel, could not well be used, because the powder settles differently and occasionally there is an increase in the weight of as much as 10 per cent. These obstacles have, however, been overcome with most of the powders.

One of the peculiarities of a small bore rifle is, that the smaller the diameter of the projectile becomes, the straighter will the flight of the shot be, because of the diminution of the air resistance. This of course has led to the adoption of very long projectiles, and in judging a powder, the straightness of course of the projectile, will have to be considered. An idea of the diminution of the height of flight can be

Fig. 8.

gathered from Fig. 8, in which there are represented the path of projectiles from the old Prussian 13 mm. needle gun of 1862, the French 11 mm. Gras rifle of 1874, and the 6.5 mm. Mannlicher rifle of 1892. It will be seen that a man of average height, say 1.6 m., or about 5 ft. 3 in., is liable to be hit at any distance up to 295 m. only with a needle gun, up to 375 m. with a Gras rifle, and up to 530 m. with the Mannlicher rifle. There is a corresponding increase for lower lying objects, as will be seen by the plain and lined parts of the diagram which represent objects of 0.4 and 0.8 m. height.

The absence of smoke in a powder has become a great consideration now, but it can be said that almost every smokeless powder produces only steam and gas without colour. The sole difference is to be found in the constitution of the gas, which in some powders may contain free nitrous acid, whereas with others, a perfect combustion takes place. At one time it was thought that armies could not long stand the fire of smokeless powder on a battle field, because of the penetrating "chemical" smell evolved, but this has been almost entirely overcome now. The marked difference in the colour of the products of combustion from ordinary black powder, and those from the new smokeless powders I shall endeavour to show to you by a method suggested by my assistant, Mr. Pollitt. It consists in burning small portions of the various powders on a tray and throwing shadows of their products of combustion on to a lantern screen.

Very important is the question of residue and heat developed. Some powders only leave a slightly imperceptible residue which is cleaned out automatically by the next shot. The heat evolved in connection with the friction caused by the residue erodes the rifling of the gun, and how delicate a mechanism rifling is, will be understood when I say that the depth of the rifling in the Lee-Metford rifle is only 0.004 inch.

A good powder should furthermore be perfectly stable under varying temperatures and should not suffer by storage in moist climates or damp stores. At the same time it is highly desirable that the powder should not be liable to explosion when struck by bullets, and that loaded cartridges should not explode "en masse" when carried in an ammunition cart.

From all this, it will be seen, that the manufacture of a good smokeless powder requires a large amount of skill and experience, and that however well devised the composition of a powder may be, it is liable to be unsuitable on account of its not fulfilling one or the other of the numerous conditions imposed upon it.

The form of smokeless powder now used is either that of grains, small flakes, cubes, or of cords. The grains vary in size. In grained powders there are between two thousand and three thousand grains per gramme. The flakes for military purposes are  $1\frac{1}{2}$  m. square, and 0.3 mm. thick. For sporting powder the thickness is reduced to 0.1 mm. The thinner the powder flakes are, the quicker they will burn

For large guns the flakes are made 3 mm. square by 0.7 mm. and upwards, or they are made in cubes of 2, 5, 10 and 15 mm. side.

Cordite and Filite are made in various thicknesses. That for the service rifle is 3.80 (0.0375) inch thick, and its diameter increases with the size of the gun for which it is used.

The colour of smokeless powder is, as a rule, in consequence of the action of the solvent, rather a dirty grey or yellow; with nitroglycerin powders, from light to dark brown. Very often the powders are polished with black-lead in order to fill up the pores and to give them a smooth surface, in which case, they have a silvery grey or black appearance.

The absorption of moisture by a good smokeless powder is very small, and if it should become damp, it can be easily dried again. An experiment made by exposing Ballistite in open saucers for a whole year has shown that most of the powders contained less moisture at the end of than before exposure.

The volumetric density of smokeless powders varies between 0.55 and 0.40. The absolute specific gravity is about 1.60 for most of them.

In this country and in most others, smokeless powders are tested for their stability against heat in a similar way to gun-cotton. But they are also tested as to the increase of gas pressure resulting from an increase of temperature in the barrel. According to an experiment made by Sir Andrew Noble with a 4.7 inch quick firing gun, Ballistite developed a mean pressure of 14.3 tons per square inch, or 2.180 atmospheres. Cordite, 14.3 tons per square inch, or 2.127 atmospheres, whereas the ordinary service pebble powder gave rise to 15.9 tons per square inch, or 2.024 atmospheres. The muzzle velocity was 2.140 ft.-seconds for ballistite; 2.140 ft.-seconds for the cordite, and 1.839 ft.-seconds for the pebble powder.

Smokeless powders are, as a rule, not explosive in the ordinary sense of the word. They burn with some difficulty and they are also fairly insensible to blows or the impact of bullets. The consequence is that they require caps of great strength, and developing much heat. They generally give off permanent gases, mostly carbonic acid and steam, but there are also some nitrogen-oxygen gases formed, which impart a slight yellow tinge and a little pungent smell to the smoke. On account of these acid compounds developed, there are always traces of acid residue left in the barrel, and unless these are cleaned out after ceasing to fire, the barrel becomes rusty.

The chemical analysis of smokeless powders is done on similar lines as that of blasting gelatine, but it is necessary to grind them in a mill in order to reduce the very hard grains to a fine powder. This grinding sometimes causes particles of iron and steel to fall into the ground powder, which have to be taken out by means of a magnet.

What I have said here, must of necessity have been of a somewhat superficial character, because on the one hand, the various Governments and manufacturers do not as a rule willingly divulge the details of their manufacture, and the knowledge to be acquired is therefore somewhat circumstantial. It is thus quite possible that not everything I told you is absolutely accurate, yet I have given you what I believe to be correct. Of course, I have not said all I could say on the subject, because this is not desirable for various reasons. All I wanted to do was to give you a general idea, to show how smokeless powders are constituted and made, and to enable you to follow this question a little more closely in the future. One thing I wish to impress upon you is, that with a comparatively new manufacture dating back only six years, it is quite impossible to have acquired all the experience necessary for the production of a powder faultless in every respect. There must, therefore, be of necessity a number of complaints at the beginning, and a large number of defects have been found in each powder in each country. In this empire especially, which extends almost from the north pole to the south pole, where there are extreme varieties of climate, temperature and moisture, the manufacture of a powder fully up to the requirements of the service, is extremely difficult, yet up to the present, it has been found possible to meet most of those defects as they showed themselves in course of time, and I have no doubt, that if the necessity for any further improvements become evident, it will be quite possible to effect them.

#### DISCUSSION.

Mr. W. F. REID said that the whole manufacture of powder for the army had become a chemical process, and on listening to the formulae that had been mentioned, they were almost transported into the benzene ring. With regard to Schultze's powder not being adapted to military purposes, that was partly due to the nature of the ash. Both that and the E.C. powder left a hard ash, whilst ordinary black powder left an ash to a certain extent soft, which afforded some lubrication to the succeeding bullets. With a hard ash the rifling was soon obstructed, the bullets stripped, and all accuracy was lost. The author had referred to him in connection with the E.C. powder, which he described as being the first powder which, if not quite smokeless, yet approached that condition, and also to his having been the first to harden the grain, by means of the action of a solvent upon the gun-cotton contained in the grain. That was the theory he had before him in working at that powder. Mr. Guttman said it was a pity he had stopped at that stage, but as a matter of fact he did not stop there, for he made a number of further experiments on gun-cotton powders, but there was a very good reason for not issuing them at that time. The use of powder for sporting guns was limited entirely to the cartridges then in use as it still was practically, and for military purposes it was quite impossible then, and still was for any English inventor to introduce any powder into the army in this country. The usual way was to bring them before a foreign government, and then that acted on public opinion, public opinion acted on the Government, and then something was done. That was the case with the smokeless powder. In 1882 he had occasion to show some French Military Attachés some of those experiments, and two years afterwards they were in full swing, experimenting on the same subject in France. The English Government took somewhat longer to get to work on the subject. In 1882 he took some specimens of smokeless powder to Waltham Abbey, and they were tried, and two points in particular were raised as being great objections, though there were others also; one was that the trajectory was so much flatter that the sights of all the rifles would have to be altered. Another was that the amount of power which could be concentrated in a given space would necessitate an alteration in the cartridges; this would involve an alteration in the whole of the rifles, and of course nothing was done. Then when the French Government took up smokeless powders, the question was brought in a very prominent way before Parliament, and before the Military Authorities. One of

the most important points in the manufacture of smokeless powders alluded to in the paper was the alleged impossibility of recovering the solvent economically, and it was said that hitherto that had not been done on a large scale. It was done on the commercial scale with the E.C. powder, in fact it was one of the first questions which occupied his attention. The solvent, which was a composition of ether-alcohol, was very expensive, and a great number of experiments were made with the object of recovering it. This was finally done in a simple manner. The apparatus consisted of a revolving drum heated externally, and a current of warm air passed through it. A very slight current was necessary, and then the air containing the solvent was cooled down, and the solvent recovered the greater portion of it, at any rate. That could be re-distilled, and used over again. As a matter of fact, this point was of great commercial importance in the manufacture of these powders, and he had no doubt that in most cases the solvent used could be recovered at a nominal cost. With regard to acetone, there was a good opening for any member of the Society who could find some means of producing it cheaply. At present it was a very expensive substance, but the demand for it was increasing rapidly. Theoretically it was possible to produce it from a variety of substances, such as sugar, and he had made some experiments in that direction, but it was not a practical process at present. He was quite sure there was a great future for chemical industry in that direction. Another point which he did not think had been sufficiently emphasised in the paper, though it must have impressed itself upon all who were present, was the great safety with which these powders could be handled. As a matter of fact they were extremely safe. If the largest cube on the table were set fire to it would not burn more violently than a small quantity of, say, petroleum, and it would not explode as black powder did. That was of great importance in handling these explosives. With regard to the general use of these powders, so far as his present knowledge went, those which contained nitro-glycerine were being rapidly superseded by those which consisted of nitrocellulose alone. So far smokeless powders had proved successful, and, as the author had remarked, they had reached a certain stage, but they hoped to do better. He thought the process of the survival of the fittest would result in the use of nitrocellulose alone. With regard to the lengthening of the projectile it was only possible to elongate it and to diminish the diameter within certain limits. Beyond a certain point such an amount of friction was produced in the rifle that the pressures became too great, and there were other theoretical reasons with regard to the flight of the projectile which prevented elongation beyond a certain extent. He believed also that doctors rather objected to a long narrow projectile. He heard of one military surgeon having stated that it was like sending a knitting needle through a man; it did not dislodge him at the moment, but it was a very difficult wound to cure. These small-bore bullets would also go through about a dozen men, one after the other. The amount of smoke developed could not be quite gauged by the appearance when the powders were ignited in an open space; it was much less when ignited in a confined space, because substances which in the open air were condensed in the atmosphere as soon as they touched cooler air became volatilised in a hot confined chamber, and did not show. These powders had a great advantage over the old black powders in respect of storage. They could be stored under water, and when taken up and dried were as efficient as ever. In 1882 he sent a sample of E.C. powder to a yachtman who was out wild fowl shooting, his boat sank, and he related with great enthusiasm that he got up the powder, boiled it, and then baked it, and it was much better than it was before; he even advised baking all his powder because he said he got so much better force with it. That showed the great advantages which modern military men had, that they need no longer keep their powder dry according to the old Cromwellian maxim. The climax of propulsive power he thought had almost been reached with smokeless powders. Theoretically the maximum effect would be produced if one could get solid hydrogen in connection with solid oxygen and detonate them together. At

the point which had now been reached they were obliged to take in some inert nitrogen also, but if they could eliminate the nitrogen and leave the other substances in a state so that they could at once be converted into gas, of course matters would be improved, but theoretically he did not think there were any much greater advances possible in this direction. The progress which would yet be made no doubt was probably in their shape or the form of the grain. One method of propulsion, though one could hardly call it a smokeless powder, was that by means of liquified or concentrated gas, and some experiments were made not long ago by M. Giffard which were not quite successful from a practical point of view, but they showed a way in which progress might in future be made. The method of cutting up the sheets of nitrocellulose after they had been hardened to form a powder was, he thought, open to very grave objection theoretically. If you could get a globular form of grain you would certainly have a better powder theoretically in every way. With flat grains there was the disadvantage of their setting or caking together, and you could never be quite sure that you had exactly the same spaces between the grains. Next to the globular form, no doubt the cylindrical was the best, but that also had a disadvantage from the point of view of ignition. On the question of ignition again the caps were of very great importance, and in this respect these powders were very different from the ordinary black powders. They required a certain definite amount of ignition to produce a definite effect, and unless the caps were very regular you got irregular results with powder of exactly the same composition, and used in the same quantity. He discovered that in a very startling way by some foreign cases containing very strong caps which were introduced for nitro-compounds for sporting purposes. The result was a number of burst-guns and accidents to sportsmen. It was very important that the method of ignition should be uniform, and in the ordinary caps this was not so. With regard to the manufacture of these powders, unfortunately as they had seen recently in the Government factories many accidents had happened, but it was rather curious that those accidents did not happen to such an extent in the private factories. There were many things which caused danger in a new explosive of this kind, and he might mention one which he found himself of very great importance, and in erecting smokeless powder factories he had always provided for it. That was electricity. One effect of covering the grains with graphite or plumbago was that it formed a conducting surface. If you shook these nitrocellulose sheets together, if they were not blacklead, they became highly electric and adhered to each other, and to everything. In fact they would often adhere to your fingers after having shaken them up for a bit. If they were faced with graphite that did not happen. Now in the Government factories it was the rule to exclude all metal from the interior of the drying sheds. But you were bound to have metal in some form in the shape of pipes and fittings, and if you covered these, which was often done, what you really produced was a Leyden jar which became charged with electricity in a warm house when the powder was moved or a current of air set in motion, in fact such a drying house was frequently a laden Leyden jar, and a spark might be produced which might cause a serious accident. The practice he followed was always to have metallic connection everywhere. Even in the treatment of dry nitroglycerine a considerable quantity of electricity was produced which he had been able to detect.

Mr. W. P. BLOXAM said the author had not made any reference to the use of smokeless powder in Her Majesty's navy, which he thought was a slight oversight, as they were greatly interested at present in the issue of this smokeless powder and its stability. Of course it would be very difficult to obtain any official utterances to the stability of cordite, and such like materials after exposure to high temperatures, but there was very distinct evidence of the high temperature of the magazines in many modern warships, and the seamen gunners and the gunnery officers were considerably exercised in their minds as to what would be the effect of the prolonged storage of cordite in the magazines of some of these ships. Again, if he followed the paper correctly,

the author did not refer to carbon monoxide, but he believed from certain statements that there was as much as 38 per cent. of carbon monoxide recognised in the products of combustion, and the seaman gunner again was not looking forward with any great pleasure to the use in closed turrets, of a material which developed such a quantity of this gas. Comparatively little, from a physiological point of view, was known of the toxic effect of this gas, but it was stated variously that from 0.1 to 1 per cent. proved rapidly fatal. He wished to know, therefore, if they were likely to have 38 per cent. It was very difficult, as Mr. Gottmann said, to get much information. They could not expect the powder to grow up in six years, and do everything it ought to do, and they must not be impatient in trying to force the hands of those gentlemen who were carrying on patient researches towards perfection, but still though the sailor was a confident man, he would not swallow everything. It was not so much a question of the strength of poor Jack as the persistent nature of carbon monoxide. Of course everything could not be stated in so short a period, but he was bound to say, being associated with naval gunnery officers, that it was of great importance to hear such an able and concise summary classification of smokeless powders, so lucidly presented.

Mr. W. MEXAN said he only had one or two remarks to make, not so much on the manufacture of smokeless powder as on one or two points which had been raised incidentally. With regard to the explosive, rifleite, he said that he had never found any alkaline or alkaline earthy nitrates in specimens he had examined, the components being nitrocellulose and nitrobenzene. With regard to the production of thick sheets of smokeless powder, no doubt it was quite correct when made with acetone or similar solvents, in order to make a thick sheet, to run several thinner sheets together, but in making the ordinary ballistite, consisting of nitroglycerin and nitrocellulose, in which no facilitating solvent is used, the sheets could be readily rolled up to about 1½ inch at once. With regard to what the last speaker said about the gas produced by the explosion, he could entirely confirm his opinion that there was carbon monoxide produced from cordite, ballistite, or, in fact, from nitrocellulose powders, to a large extent, sometimes amounting to 30 per cent. or 40 per cent. of the permanent gas. The more nitroglycerin there was present the less was the percentage of carbonic oxide, and the larger the percentage of the less harmful carbonic acid. One point which might be of some little interest was with regard to the effect of gelatinisation on nitrocellulose. He had examined nitrocellulose (gun cotton) as to the amount of heat evolved on explosion by a good sample of it containing 13.30 per cent. of nitrogen, and the result was that 1,061 calories were developed, but the same after gelatinisation, and being cut into grains yielded 922.

Mr. GETTMANN, in reply, said Mr. Reid said that the Schultze and E.C. powder gave a very hard ash, which was one of the chief reasons they could not be used for military purposes. No doubt that was one reason, but there was also the other reason that he gave in the paper, that they could not be made of such a degree of uniformity as to fulfil the very strict requirements of military purposes. As to the recovery of the solvent he simply stated that it was found impossible to recover it economically. Mr. Reid told them that they tried to do so in a revolving drum, passing heated air through it, then collecting the gas and condensing it. That was precisely the way in which it was tried by various governments, and in various countries, but found impracticable for the simple reason that when you had to deal with very large quantities, much larger than the E.C. Company had, you wanted such a large amount of drying drums and such a large quantity of air to pass over the powder in order to evaporate the solvent perfectly and absolutely that the amount of acetone contained in the air was too small to be worth recovering. This at least was the experience of various governments with which he was acquainted. Mr. Reid also said that there would be a good opening for a chemist to produce acetone cheaply. He believed there would be some opening, although he believed the quantities that were used by each government were much smaller than was generally supposed. Still a good deal of saving might be effected in that direction, and as a matter of fact he

(Mr. Guttman) had erected an acetone plant for the Government at Waltham Abbey. With regard to powders containing nitroglycerine, being rapidly superseded by those containing only nitrocellulose, as he had said in his paper he did not wish to express any opinion as to the merits of the various powders. He believed it would be wiser to abstain from so doing. Everybody had a right to his own opinion, and Mr. Reid would allow him to have his. Then Mr. Reid said the projectiles could not be elongated beyond a certain point, which was quite right. He only said that with the smaller bore the projectiles had to be lengthened. To what extent that was possible was rather a question for military men, still it had been found that a rifle with five mm. bore, or about 0.2 of an inch was quite practicable. It had been tried, and it was quite on the cards that it might be introduced somewhere. As far as the rifling of such a small bore went, there was no difficulty in making even so fine a rifling as required for that. Mr. Reid was not quite right when he said the wound produced by such a small projectile was so small that a man might go on fighting, and then afterwards find himself incapacitated. Experiments had been made with small bore bullets for a very long time, and a very elaborate work on the subject had been issued by the firm of Lorenz, of Carlruhe, who first made compound bullets. Quite recently in Austria, he was sorry to say, there had been riots, and the small arm rifle had played havoc with some of the miners, and when examined it was found that the bones were shattered more than with a large bore. They made almost incurable wounds. With regard to the amount of smoke developed, what Mr. Reid stated held good to a certain extent only. There were certain products of combustion which if you burnt a powder in the open air would simply escape by force of the combustion, that is to say, solid particles not being burnt, and that would not take place in a confined space to such extent; but when you burnt a small quantity of powder which flashed up in a comparatively long time when there was plenty of time for combustion to take place, the difference between the smoke as regarded a confined and unconfined space was not so very large. The use of liquified gas for the propulsion of bullets had been mentioned, and the experiments of M. Giffard of the sliding railway fame in the Paris Exhibition. He believed both M. Giffard and Mr. Edison, who wanted to decompose water and form gas and explode it, were on the wrong tack as far as practicality went. He quite agreed that theoretically the combustion of solid oxygen and hydrogen were probably the best things in the world, but to introduce them into practice required a genius, and he feared that manufacturers were not always geniuses. Then it was said that globular powder was better than flat powder, especially that flat powders caked together, and the flame could not be propagated so fast. He had no interest in advocating either one or the other, but all he could say was that he had on the table samples of smokeless powder of various descriptions, and every one examining Von Förster's powder would find that it consisted of a peculiar form of flakes which made them fill up an ordinary black cartridge, although the weight was only one-third, and there was plenty of air space and probably more than with globes. With a globular grain if you made it small you would have plenty of surface in relation to bulk, but if you had it too great the bulk would be much larger than the surface presented, and this might not be the case in the flake powder. For large powder like ballistite it would be impossible to make globular powder of that size. Globular powder might have its advantages as against cubical powder, but it would take too long to go into full explanation of these details; it would be sufficient to say that those who selected cubical powder had very good reasons for their choice, those who selected flakes, and those who selected the globular had also a reason for what they did. Every one tried to work in the right direction, and, as Mr. Reid said, in the result the fittest would be found to survive. With Von Förster's smokeless powder a peculiar mode of drying was adopted, which caused the flakes to crumple up, and consequently leave a great amount of air space. Reference had been made to the accidents at Waltham Abbey, and it was said that such accidents did not happen at private shops. He was happy to say that he had not yet had a serious

accident in his 20 years' experience, but he believed he was an exception. He was sorry to say that most of the manufacturers had found in starting their works, and in the beginning when they did not quite know how to work or exactly the nature of the stuff with which they were working, that there were sometimes explosions. Not so very long ago there was a very severe conflagration, not an explosion, in a ballistite factory in Italy, and there had been a number of accidents in connexion with nitroglycerine all over the world, although much less than in gunpowder works, so that they need not be surprised that there had been some at Waltham Abbey. There must always be some experiments made, but he believed they could be done with proper care. He could not speak any further on that subject as he might have to give evidence on the subject. But he thought it would be found eventually that the explosions at Waltham Abbey, except the last one, were not of such a serious character as was thought. With regard to electricity in connection with nitrocellulose powder Mr. Reid would remember that he dealt with that very fully in a paper before this Society last year, where he acknowledged his work in construction of drying houses so as to make them nonelectric. He did not think the black-leading of nitrocellulose was done with that object generally, though it had that effect; and he quite agreed with Mr. Reid that the electricity should be carried away with such powders. Unfortunately, every manufacturer did not see it in that light, and he feared they would have many gun-cotton drying-houses on fire before they realised the importance of this matter. The black-leading was generally done for the purpose of filling up the pores of the powder, and giving it a smooth surface. Mr. Bloxam had found fault with him for not mentioning powder for the Navy, but as a matter of fact he did not know of any general difference between powder for the Navy and powder for the Army, for the same effect was desired, the same class of powder would be used, and the exigencies for all of them were nearly the same. With reference to the high temperature of the magazines he thought he recollected seeing in some paper a letter asking why did the constructors of ships set their magazines so near the boilers so as to over-heat them; surely they might put them somewhere else, and if for other reasons a powder is preferred which does not stand heat so well as black powder the removal of the magazine was not an insurmountable difficulty. Then there was an answer to that, of course, that they could not alter the ships, the magazine was in the most handy place, and so forth, but even then there were means known by which such magazines could be cooled down if necessary. But in general the danger of over-heating such powder was not so great as people imagined. It would stand a good deal of heat before it decomposed or went off. Mr. Maenab had corrected him with regard to rifleite not containing potassium nitrate. He also said ballistite could be made in sheets up to 1½ ins. in thickness. No doubt it could; he believed it might be made thicker, but he did not believe they would be good sheets, or that they would work well in a gun. In making such thick sheets the difficulty of removing the air-bubbles and the solvent would be very considerable.

Mr. W. MAENAB said he referred to powder made with nitroglycerin.

Mr. GUTTMANN said he understood that, but even with these the air-bubbles would remain. Mr. Maenab had answered Mr. Bloxam with regard to carbon monoxide, and therefore he need not say much with regard to it. There would be carbon monoxide wherever there was imperfect combustion, but their aim was to make a powder which had perfect combustion; ballistite, cordite, and nitroglycerine powders in general gave perfect combustion, provided they were properly made. Nitroglycerine having an excess of oxygen in burning would always produce gases containing less carbon monoxide than others. His remarks as to heating, and so forth, were highly interesting, and he understood Mr. Maenab had done a great deal to investigate the heat developed by various powders.

Meeting held Monday, 4th June 1894.

MR. WM. THORP IN THE CHAIR.

## AN ACCOUNT OF SOME EXPERIMENTS ON THE STRENGTH OF LEATHER.

BY WALTER G. McMILLAN.

IN course of his work in the Indian Ordnance Department the author was asked by the Director-General of Ordnance in India to undertake a series of mechanical tests with the object of ascertaining the tensile strength of harness-leather made in the Government Harness and Saddlery Factory at Cawnpur, and to compare it with that of samples made in private tanneries in Madras and in England. Several hundred tests of various kinds were made, and it is proposed, with the sanction of General Walker, to summarise the more useful of these results in this short paper. Visits to the Cawnpur factory have enabled the writer to give a sketch of the system of tannage by which the leather was made, and thus to give additional interest to the research.

The factory is worked by the Ordnance Department of India, under the immediate superintendence of officers of the Royal Artillery. The foreman is an experienced English tanner, and he is assisted by several staff-sergeants instructed by him in such details as are required to enable them to supervise the native workmen in their own departments. To Colonel Baddeley, the superintendent, and to Mr. Wilsforth, the foreman tanner, I am very greatly indebted for information in regard to the details of Cawnpur tannage. The tannery is of no mean size, there being usually from 35,000 to 40,000 hides under treatment in the tanyard at a time; the currying and the subsequent fashioning of the leather into harness and saddlery components are conducted in the same establishment.

### THE SYSTEM OF TANNAGE USED IN THE CAWNPUR MANUFACTURE.

THE FACTORY is situated on the banks of the Ganges, close to the point at which it is joined by the Ganges Canal, and it is from this latter source that the water supply is drawn. The following numbers are the results of an analysis of water from this canal made by Dr. Compigné in the autumn of 1867, and recorded in a Government publication\* :—

Degrees of total hardness .....	4.7
“ permanent hardness .....	2.8
Grains of oxygen required to oxidise the readily oxidisable organic matter in 1,000 grains of water..	0.00065
Solids in 70,000 grains of filtered water .....	8.26
Volatile matters .....	0.7
Mineral .....	7.56
Earthy salts, &c. insoluble in water .....	5.07
Lime as carbonate .....	2.6
Soluble salts .....	2.5
Sodium chloride .....	1.5

With the exception of the somewhat large percentage of suspended matter, a difficulty met by allowing the supply to stand in settling tanks before use, the water appears to be suited for the work of the place.

THE HIDES are for the most part buffalo and cow hides, which come to the factory from different parts of India very lightly salted, while a few are obtained green from the Cawnpur butchers and require immediate treatment. They are said to be fairly well flayed as a rule, with but few flesh cuts and little fat. Occasionally, careless handling prior to salting is found to have produced local putrefaction, which greatly deteriorates or destroys the skin, and is made apparent in the lime pits, even if it have not declared itself previously.

THE TANNING MATERIAL used has generally been Babul (*Acacia Arabica*) bark, with a small proportion of myrabolans; within the last few months valonia has been

substituted for the latter, but all the Cawnpur leather referred to in this paper was made with the addition of myrabolans. A few experiments were tried with a view to introducing the use of Sál (*Shorea Robusta*) bark in place of Babul, but the leather so prepared was somewhat hard and dark-coloured, and gave a distinctly inferior test, as the numbers quoted hereafter will show. Babul bark, which is abundantly obtainable from local contractors, has been found by Christy to yield 18.95 per cent. of a good cream-coloured tannin; a sample given to the author on the occasion of his visit to Cawnpur in 1893 gave 21 per cent. of tannin, while a specimen of Sál bark yielded only 9 per cent. The bark is said to be of fairly constant strength, showing only a slight loss of tannin (by exposure) during the rainy season. The exhaustion of the bark is effected in latches, which are worked in series of eight, giving different solutions, with a range of from 2 to 50 barkometer. The latches are of brick with wooden false bottoms, and are of three different sizes in different sheds. The sizes and weights of material employed are as follows:—

Size of Latch.	Charge of Bark.	Charge of Myrabolans.
12' x 19' x 8	Cwt. 51	Cwt. 15
16' x 10' x 8	50	15
10' x 9' x 6	35	10

The tan liquors are returned to be refreshed, to one or other of the latches according to the strength indicated.

THE TANNING PROCESS is conducted as follows:—

The hides are soaked in pits, in which the water is changed whenever, from its appearance, it is judged to require renewal; they are then stocked for about half an hour in a gentle stream of running water.

They are next limed in a series of six pits, each fresher than the last. The lime pits are, as usual, worked in rotation, being made up originally with 5 cwt. of lime to the pit; this liquid lasts for about a month without further addition of lime, and treats about 700 or 800 hides. Each hide may remain in the limes for from 15 to 18 days, but in the hottest weather a somewhat shorter soaking suffices.

They are now unlimed and fleshed, and are then bated in a liquor made up by extracting seeds from the pods of the Babul tree with water. This bate has originally about 2 cwt. of the seed to each pit, and lasts about three weeks; a gentle fermentation is initially set up by the addition of a few buckets of tan-liquor. For light leather a bran bate is generally substituted. The process demands careful attention at all times, but particularly in the hot season.

The hides are now at once transferred to handlers containing weak liquors (7° to 8°) for two or three days, being handled every two or three hours during the first day. The spent liquors from this vat are allowed to run to waste. After this, the skins are handled daily for about a month in stronger liquor (15°); then for a month in “floaters” in liquor of about 20°; next they are transferred to “dusters” working at a strength of 30° and containing a small proportion of fresh bark; here they are handled daily for from one to two months, and are then put away for about six months in layers, the liquor-strength in which varies from 35° to 50°, but averages 45°. Each layer-pit contains, in addition to the liquor, 4 cwt. of bark and 2 cwt. of myrabolans, and treats 100 hides.

CURRYING.—The hides are now transferred to the curriers' shops, where they are successively shaved to the required thickness, scoured on flesh and grain, passed rapidly through weak sumach liquors, oiled with cod-oil, sammed, and struck out, re-shaved or flatted, stuffed with a mixture of cod-oil and tallow (in equal parts in the cold weather, but containing 50 per cent. of tallow in the hot season), and are finally dried out and finished by the removal of surplus grease.

In all the processes here described, the average treatment has been given; but this must of necessity be greatly modified at different seasons in a climate which is equivalent

\* “Statistical, Descriptive, and Historical Account of the North-West Provinces of India,” Vol. VI., p. 223.

to an English summer in the cold weather, where the thermometer may daily rise for several months to over 100° F., when a very small proportion of atmospheric moisture exists, and where for two or three months the atmosphere may be saturated with water vapour with a thermometer indication of over 90°.

Concerning the processes used in the preparation of the Madras and of the English leather, the author has no information. The latter, however, was taken from a large number of hides supplied to the Government by a good firm of English tanners.

The tests to be described were made chiefly with new leather. Half hides were supplied to the author's Department and were cut, under his direction, in the manner detailed below. A certain number of the Cawnpur (Babul- and Sâl-

tanned) English hides were made up at Cawnpur into harness components, were issued to a battery of artillery, and, after six months' service, were returned for test, and were then cut up into straps of suitable shape and size for the testing-machine. The testing-machine was one of Greenwood and Batley's lever pattern, and although intended and generally used to test metallic specimens up to a 100-ton load, was yet equally adaptable to the measurement of any stress exceeding 500 lbs.

#### TESTS OF NEW LEATHER.

The half skins being submitted, straps measuring in the test-portion 10 inches in length by 2 inches in width, were cut from different positions in the hide, as indicated in the annexed diagrams.

Method A. of cutting: with test-portions in "means" of straps a and e.

Method B. of cutting: with test-portions in "extremes" of straps a and e.

N.B.—The shading (10" x 2") indicates the actual portion of the strap on which the test is made and measured.

"    light, <i>mean</i> .....	6	24	0.163	1,040	5,080	28.0	6.5	24	0.142	1,270	4,540	27.0	5.7			
Madras, <i>mean</i> .....	3	12	0.141	1,480	5,360	28.0	6.4	12	0.212	1,890	4,900	29.0	6.8			

Half of the hides were cut according to method A, half according to method B; only the straps *a*, *c*, *e*, and *f* were tested in the usual way, the intervening strips *b*, *d*, and *x* being reserved for special tests. All pieces marked *1* are considered to have come from the neck half, those marked *2* from the rump half of the hide.

The test portion was always of the size quoted ( $10'' \times 2''$ ), and the edges and corners were carefully and evenly cut. The thickness was measured by means of a micrometer gauge at 2-inch intervals of length, so that the thickness at the point of rupture might be accurately known. The short end of the piece was gripped directly by the jaws of the testing-machine, and the long end was turned over on itself, and stitched on to form a loop which passed over a large pin, placed in the moving cross-head of the machine. The 10-inch length, forming the test portion, was thus freely suspended between the supports of the machine. To

ensure rupture occurring in the desired part, the test portion was cut  $\frac{1}{2}$  inch narrower than the ends, which were left  $2\frac{1}{2}$  inches wide.

The tests of six Cawnpur (Bahul), twelve English, and three Madras hides are dealt with in Table 1.

For the sake of showing the variation in strength at different parts of the hide, the above results have been worked up into the following diagram, which may to some extent be regarded as representing the distribution of strength in typical hides, every number quoted being the mean of the breaking loads of all the straps from similar positions in hides of the same class. The straps marked *a* were nearest to the back; those marked *f* were within a short distance of the belly edge of the skin, the letters corresponding to those given in the diagrams sketched above.

NOTE.—The ordinary figures represent the actual breaking load in pounds; the antique figures *a* to *f* the stress in pounds per square inch of sectional area.

A few tests were next made to determine the relative values of the leather samples when saturated with water. In Table 3 will be found recorded the strength of the wet straps, together with the difference per cent. of this result as compared with that of a normal (dry) test of a strap cut from a position immediately adjacent in the same hide. The straps were allowed to soak in pure water for 18 hours prior to testing, and were transferred to the testing-machine directly they were withdrawn from the water. The excess water became rapidly wrung out of the leather as stress was applied and stretching set in, and at the conclusion of the test the strap was only damp. It does not appear that the wetting has appreciably altered the strength of the leather, as the results varied on both sides of the normal, and the mean difference of 5 per cent. is scarcely sufficient to indicate a serious diminution based on so few results.

In order, if possible, to ascertain how far statements of test results reported on the square inch of cross section were reliable for samples which had not undergone perfectly uniform treatment under the fletcher's knife, a few tests were made with specially shaved hides. The straps were thinned evenly down with a sharp knife by men accustomed to working with leather, until about half of the substance

had been removed from the flesh side, leaving the grain side intact. The results of the tests are given in Table 4, and a comparison is made with normal tests from adjacent straps. It will be seen that a reduction of thickness equal to 50 per cent. reduces the strength, on the average, by about 15 per cent., while the extensibility under stress is considerably increased. I may here mention that in some earlier tests not reported in this paper, a deep flesh cut which occurred across the centre of one strap appeared to have no appreciable influence on the result.

Finally, a tearing test was made by passing a round steel hook  $\frac{1}{4}$  inch in diameter through a clean-cut hole in the leather, and applying tension through this hook, noting the point at which the hook began to tear through the hide, and that at which complete rupture resulted.

In Table 6 is given the average thickness and weight, both per sq. in. of surface and per cu. in. of substance, of the hides examined, as found from the measurements made of the various straps cut from each.

\* The number of hides tested is of course insufficient to give a good average.

In order to throw further light upon the nature of the leather tested, its absorbing power in regard to water was taken, and also the specific gravity of the material when saturated with water, the results of this examination being recorded in Table 7. It will be noted that the most absorbent and least dense leather was that of Cawnpur manufacture, next the Madras, and last the English, which order represents also that of their respective tenacities.

Summing up the work, the highest and lowest normal tests, and the mean of each series, together with the results of the tests of the experimental salt-tanned specimens, are included in Table 8.

#### TESTS OF USED HARNESS-LEATHER.

The only tests which it was possible to make on the standard size of strap (10" x 2") were cut from the central portion of leather girths, and these results are included in Table 8 (above) for convenience in comparison with those obtained from unused leather. The size or shape of the other harness components would not admit of the cutting of so large a strap; all the remaining tests were therefore made upon the longest and widest pieces that could be cut in any given case.

" " English ..	5	720	500	570	3,630	2,440	2,990

In Table 9 it will be noticed that the tests are higher than the corresponding tests of used straps 2 inches wide, recorded in Table 8. The author has had other evidence, however, confirmatory of the observation that a narrow strap is proportionately stronger than a wide one.

The special interest attaching to Table 10 is to be found in the indication which it gives of the extent of the weakening produced by perforations made to receive the tang of a buckle.

Finally, it may be observed that tests of the raw hide and of the semi-manufactured hide gave the following results—

	Actual Strength.	Strength per Square Inch.
Mean of 5 tests: 12 specimens (untested) ..	Lbs. 1,376	Lbs. 6,000
" " " " " " " " soaked hide, after soaking ..	1,300	10,226
" " " " " " " " stocking ..	1,096	8,420
" " " " " " " " bathing ..	750	5,310
" " " " " " " " dusting ..	970	5,080

The strips used for these tests were taken at random from the Cawnpur tanyard, and were tested on the machine in the author's laboratories at Cossipur, after an interval made as short as possible, in order to avoid deterioration by putrefactive action.

Finally, to bring to a focus a few of the points which appear to be indicated by the experiments quoted in the paper:—

A. In comparing the leathers produced by the two systems of tannage, that which had the lower specific gravity (wet or dry) was to a marked extent more absorbent than the other, and was at the same time stronger both actually and per square inch of section, but stretched less before rupture.

B. In leather produced by a given system of tannage—

1. Thin hides are stronger per unit of sectional area than thick hides, while the ultimate extension before rupture, although practically the same, is on the average slightly greater in the stout or specimens.

2. Thin hides are more absorbent, and have a lower specific gravity when wet than thick hides.

3. In any given hide, omitting from consideration the extreme neck portion of the back, which is altogether inferior, straps from the rump half should carry a higher actual load by reason of their greater thickness, but will nevertheless stand a lower stress per square inch than those from the neck half.

4. With average hides, a comparison of strength per unit of sectional area is permissible, but shaving or an exceptionally severe use of the fleshing knife may lower the strength per square inch of section, while it increases the extensibility.

5. Other things being equal, a narrow strap may be expected to be not only stronger than a wide one, both actually and per unit of sectional area, but also to stretch more under a given load.

#### DISCUSSION.

The CHAIRMAN said he hoped there were some specialists present acquainted with leather who would be able to discuss this paper. Mr. Macmillan had said he was rather sorry the English leather stood the tests worse than the Indian, which was perhaps a natural feeling, but it must be remembered that the Indian leather was tanned under English management, and perhaps climate had something to do with its superiority. As a simple matter of mechanics he was rather surprised to hear that a narrow strip should be stronger than a wide one. The idea of a thin strip being stronger than a thick one was more easily understood, because the greatest strength of leather was in the surface of the skin, and there would be more surface in proportion in thin leather than in thick. But it was perplexing that a narrow strip should be stronger than a wide one.

Dr. C. R. ALDER WRIGHT said he did not know whether Mr. Macmillan had any reason to suspect that any of the samples of English leather had been "dressed," which he believed was the euphemism for treating it with various materials with the object of giving it extra weight. Some few years ago there was a great deal of disturbance in the

minds of the officials at Woolwich and elsewhere with regard to the Government saddlery, and inquiries were made as to the quality of the leather supplied. He had then occasion to examine a considerable number of samples, some of which had, and some had not, been subjected to these weighting operations. One sometimes read in works of fiction of a man being wrecked in the Southern Pacific, and subsisting for a long period by sucking strips cut from his jack boots; but, as a matter of fact, some of the leathers in the market, if not absolutely competent to support human life for several weeks, had so much glucose and other nutritious materials in them that at any rate if boiled down, with the resources of a French *chef*, they would make a very nutritious soup indeed, as they would include these non-nitrogenous constituents as well as gelatinous matter. There was as much as 10, 15, or even 20 per cent. of glucose in some "dressed" leathers intended for saddlery, and he had examined a roll of leather where the average contained ran up to nearly 30 per cent.; he had obtained brandy, or spirit at any rate, in considerable quantity from the fermentation of the glucose extracted from such leather. He did not know how far a possibility of this sort might account for the inferiority of some of the English samples subjected to test. The object of this treatment was to add to the weight, but obviously it must add somewhat to the thickness, and perhaps to the rigidity; a sample treated in such a way containing 70 per cent. of actual leather, representing 100 per cent. as sold, would necessarily indicate a very much less degree of tenacity when reckoned on the 100 total material than if on the 70 parts of actual leather. Whether that were the case or not the difference between the breaking strain exhibited in different parts of the hide was certainly very valuable information, and the thanks of the Society were due to Mr. Macmillan for bringing these carefully-made observations before them.

Dr. S. RIDEAL said Dr. Wright had drawn attention to a point he was about to make in connection with this work of Mr. Macmillan. He was going to say that in leather tests of this sort it seemed very desirable that an analysis of the leather should be made. A determination of the nitrogen content of the leather would have given most valuable information as to the amount of tanning that had taken place on the different samples. Mr. Macmillan had given an elaborate description of the method adopted for tanning in Cawnpore, but whilst stating that the English samples came from an English tannery of good reputation, there was no information as to the process adopted, the length of tannage, or the materials used. If he had determined the nitrogen content one could have judged how far the tanning had proceeded. With regard to the tannage in Cawnpore, and the babul bark, he had never been in India, and knew very little about the botany of that country, but he believed that name was given to several trees of the acacia tribe, and that these acacias gave varying amounts of tannin, and tannin of different kinds, so that it was rather important that the exact kind of tree and not only the general name babul should be given. He presumed the *valonia* used was imported, and it would be interesting to know where it came from, or whether it was found in India. The bate was rather an interesting point, and he should like some further information with regard to the babul seeds and the fermentation set up. The bran fermentation was the common method in this country, and the bacteriology of the process had been studied. It would be interesting to know whether the same organisms are active in the babul-seed vats. The information as to the strength of strips of different sizes seemed to be very interesting and valuable, and he knew of no similar work having been done, so that the author was to be congratulated in bringing his results before this Society.

Mr. W. G. McMILLAN, in reply, said he was afraid he could not add much to the information that he had already given. With regard to the weighing of the leather, he had not observed any evidence of the addition of soluble organic matter, or of mineral substances remaining in the ash in the samples examined. He did not profess to be able to judge accurately of the quality of leather by inspection, but he had the opinion of the foreman tanner of

Cawnpore that the English samples were distinctly good, and he had placed on the table some of the leather for inspection after the meeting. He had not made nitrogen determinations owing to pressure of other work, which precluded him from undertaking anything beyond what was absolutely necessary; but if Dr. Rideal liked to have some specimens he should be glad to hand them over to him, or possibly he might be able to find time later on to make the determinations himself. The paper purported to deal primarily with the Cawnpore-tanned material, of which the tannage was described. The results of the English tests were, however, given for comparison. It is possible that the superior tenacity of the Indian leather may be due to the lighter salting which may have been given to a material to be used locally, than to one which was to be shipped and stored perhaps for months before tanning. With regard to the valonia, it had only recently been introduced, and was imported, but in all the experiments he had referred to myrobolans had been used; it was only within the last twelve months that valonia had been employed. Before he came away he saw a sample of local valonia which was to be tried, but he had not heard the result of the experiment. The bate was prepared by crushing the babul seeds and mixing the meal with water, the quantities used having been stated in the paper; a small quantity (about a pailful) of the old vat-liquor was added to set up the fermentation, which then went on quietly, regularly. He was told it lasted for about a month. Some authorities and Indian books stated that babul seeds were used as a tanstuff, but that was a mistake, which possibly arose through their having been used for bate; they contained practically no tannin.

## NOTE ON THE COLOUR OF BRASS.

BY WALTER G. McMILLAN.

So long as anything has been known as to the nature of the alloys of copper and zinc, certain distinctive colours have been associated with certain classes of brass. But the author is not aware that any attempt has been made to distinguish the minute gradations of shade corresponding with slight modifications in the percentage composition, or to apply these variations systematically to any practical use.

He therefore takes this, his first opportunity after returning to England, to exhibit two sets of glass tubes containing drillings of brass carrying varying percentages

of copper (71 to 63) which he collected in 1893 as the result of observations made upon alloys used in the manufacture of brass strip intended for the manufacture of cartridge cases.

In course of his ordinary duties he had made several hundreds of analyses of cartridge-metal, and a large increase in the volume of other work led him to enquire with what degree of accuracy the composition of the metal could be determined by inspection. A collection was made of all samples which had been analysed and were still in store, and these showed a range of colour from pale yellow in specimens containing 70 per cent. of copper, to a peculiar brownish shade of yellow in those having only 63 or 64 per cent. The general result was satisfactory, but the gradation from end to end of the range was not perfect. It was then remembered that the specimens were not all of identical origin; some of the drillings were from the cast ingot, others were from rolled strip; again, some drillings in each class were taken from a very pure alloy intended for the manufacture of the solid-drawn cartridge cases of the new magazine rifle, while the remainder were from brass which would be used as sheet or strip, and was less pure. A separation of the samples into the four groups mentioned, viz.:-

- A. Pure brass (i) cast and (ii) worked,
- B. A less pure alloy (i) cast and (ii) worked,

formed four series, each practically perfect in itself, but differing in colour to a slight but very appreciable extent from each of the corresponding series.

After the opening of the investigation, but before the grouping of the samples had been effected, a colour observation was made with each fresh specimen received for test whilst the gravimetric determination was in progress, but the standards and the new sample were examined in common German glass bottles, and these interfered with the accuracy of the readings. In this way 39 samples were were tested, first by inspection and then by analysis (electrolytically), and the two results were compared; out of these 39, 22 samples gave a higher reading by colour than by analysis, the variation ranging from 2.18 to 0.04 per cent., and averaging 0.76 per cent.; and 17 samples gave a lower reading, the average *minus* variation being 0.56, and the extreme 1.4 per cent. The two extreme samples (varying by + 2.18 and - 1.4 per cent. respectively) were the first two experimented with.

After the division into groups had been made, the standard specimens were sealed up in glass tubes, and, for comparison, the sample to be reported upon was introduced into a similar tube sealed at the one end and closed by means of a cork at the other. The actual results of the first 21 consecutive tests (and in fact the only tests) thus made were as follows:-

With Drillings from (rolled) Strip.

	Copper Percentage.		Variation.
	By Colour Estimation.	By Analysis.	
1	66.0	66.00	0
3	65.6	65.60	0
5	65.6	67.86	- 0.76
7	65.2	66.41	- 0.21
9	65.7	65.88	- 0.13
11	65.5	65.08	- 0.58
13	64.8	64.89	- 0.09
15	66.4	65.83	+ 0.57
17	67.1	67.23	- 0.13
18	66.0	66.34	- 0.34
21	65.0	65.35	- 0.35

With Drillings from (cast) Ingot.

	Copper Percentage.		Variation.
	By Colour Estimation.	By Analysis.	
2	65.3	65.03	+ 0.27
4	63.1	64.70	- 1.39
6	63.4	64.32	- 0.92
8	64.3	66.06	- 1.76
10	66.0	67.25	- 1.25
12	66.0	66.62	- 0.62
14	66.0	64.37	- 0.37
16	64.5	65.02	- 1.72
19	64.0	64.89	- 0.89
20	64.4	64.44	- 0.04

It will be seen that in the case of samples taken from ingots the highest variation was 1.76, and the mean variation 0.56 per cent., while with those from rolled strip the maximum difference between the actual and the estimated copper percentage was 0.76, and the mean difference only 0.21 per cent. The cause of the closer approximation in the case of the rolled, as compared with the cast, samples is undoubtedly due to the method of drilling the specimens by the native workmen in the engineering shops; those from ingot metal were obtained from small rectangular blocks about 4 in. by  $\frac{1}{2}$  in. by  $\frac{1}{2}$  in., and in drilling these the brass was often allowed to become so hot (owing to friction) that a perceptible film of tarnish resulted, and slightly altered the colour of the alloy. With the rolled strip, the samples were taken from thin sheet, which was drilled intermittently and therefore never became more than slightly warm. For this reason the possible accuracy of the process can be estimated fairly only from the numbers obtained with rolled strip. It is possible, too, that the observed difference in colour between cast and worked metal may be, in part, due to the slight film of tarnish which was so often present on the drillings from the former.

In the comparison of the samples, the general colour effect in the tube is produced by a combination of reflected light from the smooth cut faces of a few of the drillings with the more or less scattered rays from the rough surfaces on the under sides of the remainder; the difference between two specimens was, however, most accentuated on the rough faces.

In all the experiments recorded in the above table, the percentage of impurities in the brass was very constant, the lead ranging from 0.75 to 0.10 per cent., and the iron from 0.08 to 0.20 per cent., no other foreign substance being present in appreciable quantity. On one occasion, however, a sample was presented which had a peculiar greyish shade, and could not be fitted into any place in the series, although the percentage of copper was 65.9; the effect was produced by an abnormal (0.27 per cent.) proportion of lead. Any very marked variation in the percentage of impurities is always accompanied by a modification of the colour of the alloy.

It is believed, then, that the colour of brass drillings may be utilised to give rapid approximate indications of copper percentage, correct to within 0.5 per cent., or, with care, to within 0.25 per cent. But the following conditions must be observed to ensure accuracy:—

1. The samples and standards must be similar; this offers no difficulty if the same brands of copper and zinc are employed—and the same class of scrap—so that the only appreciable variables in the alloy are copper and zinc. In applying the test to alloys varying greatly in respect of purity, different sets of standards must be arranged to correspond with the metal under examination.

2. The method of drilling the samples should be uniform in regard to depth of cut and rapidity, and as far as practicable to the sharpness of the tool.

3. The formation of tarnish must be guarded against, whether it arise from heating during drilling or from subsequent exposure to the air. The samples should therefore be drilled slowly and protected from undue heating; while the standards should be preserved in sealed tubes, and the specimens under test should be examined as soon as possible after drilling; if delay be necessary they should be kept in well-closed tubes or bottles.

4. The specimen tubes should be of uniform size and colour.

The colour test is not therefore suitable for use in a general laboratory to which alloys from unknown sources are constantly supplied, and from which accurate results are expected. But it might be useful to the manufacturer who

is called upon to make cartridge metal or other brass to specification, if he use the same brands of raw materials, as the occasional analyses of the output may be supplemented by colour observations with any number of intermediate samples, inasmuch as the test is very rapid and requires no expenditure upon reagents. When the copper-zinc alloys are made in reverberatory furnaces, the application of the colour test would enable the melter to ascertain the composition of his bath within a few minutes, and thus to bring it to any desired composition by the addition of a known weight of either metal. To effect this, a fair average sample would be withdrawn from the bath, poured into a small open mould, cooled, drilled, and examined.

Only 60 trials in all (39 with bottles and 21 with tubes) have been made in this manner, and the results of all these are included in the above description. It is quite possible, therefore, that with due observation of the precautions laid down, a closer approximation than is here recorded could be secured.

#### DISCUSSION.

Dr. C. R. ALDER WRIGHT said Mr. McMillan had given the metallurgist a very valuable hint as regarded the possibility of getting rapid information as to the composition of alloys in the course of formation by physical tests such as the colour test of the drillings. In this particular case he believed the scientific basis of his proposition was that a definite compound of copper and zinc existed containing two atoms of copper and one of zinc, forming a definite molecular compound as distinct in its character as  $\text{SO}_3$ ; so that if you had a mixture of copper and zinc exactly in that proportion you had a single definite entity, but in actual practice this was a very exceptional occurrence; probably one or other of the two constituents was in excess, and there might be a small quantity of other impurities, such as lead, iron, or tin. But whether there were an excess of copper, or of zinc, or something else, the effect was more or less marked according to the circumstances not only in the physical property of the colour of the light reflected from the freshly-cut surface, but in various other respects. As he understood, the series of experiments were made on the one hand with an excess of zinc varying from 1 per cent. up to 2 or 3 or more, which gave a certain series of colour values, and on the other side with a corresponding excess of copper over and above the atomic compound which gave various other shades of tint in the opposite direction. It was by no means to be supposed *a priori* that corresponding quantities of other metal such as lead, iron, and tin, would produce exactly the same alteration in shade, and therefore, as the author had pointed out, a series of standards applicable to one set of alloys of a given character and standard of purity would not necessarily be applicable without certain alterations to metal containing other impurities. Still the figure he had given showed that a scale was possible of formation which might be of very great practical value to the metallurgist in general. It was noticeable in connection with these alloys that the yellow shade of brass entirely disappeared when the quantity of zinc present exceeded a certain amount. He had been working for some time past in connection with alloys, and in reference to this particular pair of metals had found that if you took zinc just melted at a temperature a little below that of boiling sulphur and stirred it up with fragments of copper which had been previously coated with zinc by immersion in an acid solution of zinc chloride, and then dipping into melted zinc, the zinc would only dissolved at that temperature a limited amount (a few per cents.) of copper, and you had a perfectly white alloy. At a slightly higher temperature the zinc would still remain white. In making a series of solubility determinations at various temperatures there were great practical difficulties in getting saturated solutions, whilst avoiding super-saturation; but assuming you could get the values fairly correct it was possible to plot out a curve

\* It has been suggested by Mr. Thorp that the colour of the brass might change during the first few hours after casting owing to a molecular alteration. I have therefore made up a sample, and examined it within 10 minutes of solidification—and again after a lapse of 24 hours, and have not been able to detect a change—although the colour varying a little from that of my standard specimens, comparison was not quite so easy as it would have been with the same brands of copper and zinc; the metals used for this test were less pure than those employed in India.

where the temperatures were shown by the abscissa, and the amount of metal dissolved the ordinates, and in that way it could be readily shown that at a comparatively low temperature the amount of copper taken into solution by the zinc was small, but gradually increased at an increasing rate until by and by you got perfect miscibility in all proportions of the two metals. This appeared to be not merely a property of copper and zinc, but one common to the majority of metals. On cooling down a saturated solution, however, you did not always get the reverse action taking place. There seemed to be a peculiar physical character inherent in most metals, tending to prevent an excess of matter which was dissolved at a given temperature from separating out on cooling in the same tolerably rapid way that a saturated brine at 100° would deposit the surplus of saline matter on cooling down to a lower temperature, and similarly with other watery solutions of salts. Metals seemed peculiarly prone to take into solution at a given temperature certain quantities of other metals which were not thrown rapidly out of solution on cooling. In point of fact the results he had arrived at so far led to the belief that the great bulk of alloys with which they had to do in ordinary life were more correctly described as solidified *supersaturated* solutions than anything else. He did not know that there was an exact analogue to that in watery solutions. You could obtain a supersaturated solution, say, of sulphate of sodium which, until particles acting as nuclei got into it, did not solidify; but when it did, it did not solidify *as a whole*, but separated into two things, one the solid particles of hydrated salt which came out of solution, and the other a watery solution saturated at the particular temperature obtaining at the time of observation. You did not get that sort of thing with a number of these metallic solutions or alloys. For example, if you took the alloys of copper and tin, at the temperature of melting tin, the tin would only dissolve a few per cents. of copper; at a higher temperature rather more; whilst at the fusing point of copper the two metals were miscible in all proportions. Now, taking a mixture of copper and tin, say, of equal weights, forming a saturated solution at the temperature of melting copper, if you cooled it down quickly you got a perfectly homogeneous mass, which to the microscope and all physical tests was absolutely uniform in structure. But if you cooled it slowly you had a separation into two materials; one a solid substance separating out which in all probability was a compound of copper and tin of a uniform definite atomic character analogous to the compound of copper and zinc in the case of the alloys examined by Mr. McMillan; the other remained fluid, and was a solution of copper in tin, which contained not only the amount of copper appropriate to the prevailing temperature, but also such an additional amount as the conditions might cause to remain in supersaturation. Similarly, in many, if not in most, analogous cases, as was well known to everyone who had to do with the cooling of mixed metals, you might get a mixture uniform or non-uniform in texture, according as the cooling was quick or slow. The fundamental principle at the bottom of all this was that there were certain circumstances, amongst which the presence of foreign matter was to be reckoned, which caused delay in the separating out of the matter which was in excess in solution at the moment of solidification, so that what you got was a material which, if it were to be compared with solution of sulphate of soda would be more akin to one of Guthrie's cryo-hydrates than to the mixture of crystals of sulphate of sodium, and the watery solution saturated with salt which one got in the ordinary experiment. This physical condition of supersaturation of solutions was a matter which it appeared to him was a considerable interest to all who had to deal with the alloys in question, and these particular experiments with reference to this special alloy had a very important bearing on the subject viewed from this point.

Mr. W. T. REID asked Mr. McMillan if he had made any experiments in comparing plane polished surfaces of metal. It seemed to him that the production of the shavings in the first instance might possibly produce a source of inaccuracy in unpractised hands. If it was all done by the same person no doubt the results were comparable, but it seemed rather a difficult thing to get shavings

of exactly the same character. Filings appeared to be a better form, and he should like to know whether experiments had been made with them because they could be produced of regular quality. With regard to the durability of the standard, he should like to know how long it had been in use, and also if such standards could be kept for any length of time so as to be available for future years. He had had occasion to make some experiments on metals and alloys of a darker colour than these, and found it very useful to take the streak, as was well known to goldsmiths. He first tried the streak on unglazed porcelain, but found that was not very satisfactory, and was about to give up the idea when it occurred to him that he might try a quartz surface, and on trying a surface of white quartz he found it extremely satisfactory. For some reason he could not explain this gave a colour clearer and plainer than unglazed porcelain. He then tried surfaces of dull ground glass of different colours, and was able to get very satisfactory indications, though he had not followed them up further. With regard to that interesting alloy, which possessed a different colour from the other, could Mr. McMillan tell them whether it was ductile or if it differed in that respect from the other brasses which were compared with it?

The CHAIRMAN said he was much interested in Mr. McMillan's papers when he first saw them, for he had been kind enough to send them to him some few days ago. In passing, he might venture to say that it would be well if the authors of all papers would send them to the chairman of the Section, whoever he might be. With regard to the latter paper especially, he was interested because the numbers obtained were exceedingly close. The author had carried out the experiments very fairly and carefully, making his sight comparisons before the analyses, so that there could be no kind of bias in the matter. Such approximate methods of examination were undeservedly neglected. In a large number of processes, with care to secure similar conditions, much might be done by careful inspection and comparison. In this case the author had very precisely laid down what those conditions must be. The materials must be of the same kind, and so forth; in fact the only variant should be the proportion between the two constituents of the brasses.

Mr. W. G. Mc MILLAN, in reply, said he had tried several experiments with a view to determining the best manner of observing the colour of the metal, and he distinctly preferred the result obtained with the mixed reflections, partly from the rough surface, and partly from the smooth. He had tried several alloys with polished surfaces, but although there were differences in colour, it was impossible to read them so accurately as in the case indicated. The fracture of the ingot would give a much better reading than the polished surface, but the best of all was obtained from the combination of the two. He had not tried many experiments with filings, but as far as he had observed, they were inferior to the borings taken by the ordinary boring tool. The samples exhibited were made over a year ago, and he did not apprehend they could change colour, unless from molecular alteration, because they were in sealed tubes. The alloy containing 1 per cent. of lead had a distinctly different character from that of the ordinary alloy; the turnings came off in finer flakes, which crumbled up readily on rubbing. With small quantities of lead the drillings were normal. In conclusion, it seemed to him that these experiments gave additional evidence of the effect of small quantities of metal in altering the physical characteristics of alloys, and indicated very clearly that if one wished to ascertain the true character of definite alloys, it was necessary to ascertain initially that the metals were absolutely pure and free from even traces of any impurity.

## THE DISTILLATION OF PEAT.

BY P. DVORKOVITZ, D.Sc.

It is with very great reluctance that I venture to approach the subject of peat treatment in face of the strong prejudice which exists against any method for its profitable utilisation; moreover, geologists and botanists having after careful research ignored its usefulness, it remains for the chemist to determine whether it can be turned to profitable account; hence with this object in view I have recently visited Ireland and, supported by considerate Government influence, have inspected the principal peat districts, procured reliable samples, and I propose to place before you as concisely as I can the result of my experiments.

Although peat has been known so long ago as B.C. it is only lately that it has excited a certain interest, it having been brought before your notice in very able addresses by two of your presidents; in 1889 by Mr. Ludwig Mond, and in 1892 by Professor Emerson Reynolds, and I think that as our Society has for its main object the furtherance and development of chemical industry in the United Kingdom, a few remarks on the development of the distillation of peat may interest you.

Before showing how peat could be treated, I will explain what it really is. Generally, opinions as to the origin of peat are diverse. First, that peat is mainly received by the decay of forests, and this view is supported by Mr. H. O'Hara in his paper read before the Royal Dublin Society in 1864. He says that abundant proofs exist that peat bogs in Ireland are mainly formed from forests, and that formerly Ireland was one vast forest. In times of warfare broad tracts were cleared to facilitate military operations, and extensive woods were consumed by fire. Immense quantities of timber were likewise consumed by the forges and iron furnaces, which at various times were in a state of great activity. The remains of these ancient bloomeries which are found in the counties of Antrim, Leitrim, Roscommon, Sligo, Tyrone, Killarney, Carlo, Tipperary, Limerick, Kerry, and Cork, prove that smelting of iron was very generally known in Ireland previous to the exhaustion of wood.

The destruction of the forests caused a considerable change in the climate and a still greater change in the soil; indeed the most remarkable fact has been the conversion of nearly one-seventh of Ireland into a swamp. This results from the greater exposure of the surface of the land to the moist winds of the Atlantic which are highly favourable to the growth of a species of moss known as *Sphagnum Palustre*. This moss thrives only in exposed situations and so favourable is the condition of Ireland to its propagation that if the existing arable and pasture lands which have a south-westerly exposure were abandoned to nature, most of them would be covered by peat moss to a depth of several inches in the course of a century.

Captain Portlock, in his account of the survey of Londonderry, is of opinion that sphagnum is acted upon by the superabundant moisture of the climate in inducing the formation, and this opinion is supported by Mr. Aher, who shows that trees are found generally six or seven feet above the bogs, standing as they grew, conclusively proving the foundation of peat to have been prior to the growth of the trees; a fact which in relation to fire may be verified in every bog in the parish of Donegal where turf exists from three to five feet underlying the layer of such trees.

Further Messrs. Nimmo and Griffiths in their bog report are of opinion that the strong resemblance to ancient water courses of the valleys and basins which now contain the bog, and the accumulation of marl and shells at the bottom of the moss naturally suggest the idea of shallow lakes. Such lakes may have originated in natural inequalities of the ground or been formed by the choking up of channels of transit by heaps of clay and gravel, or they may have been reduced to a condition of shallowness by the gradual wearing away of the obstacles which had blocked up and retained their water at a higher level. In all such cases the origin and formation of bogs would be as follows:—A shallow pool induces and favours the vegetation of aquatic plants which gradually creep in from the borders towards the

deeper centre, mud accumulate around their roots and stocks in a spongy semi-fluid mass specially conducive to the growth of moss, which latter, particularly sphagnum, begins to luxuriate, thus absorbing a large quantity of water and tending to shoot out new plants above, while the old ones are decaying, pressing the lower ones into a solid substance, and gradually replacing the water by a mass of vegetable matter. In this manner a marsh might be filled up, while the centre moisture portion continuing to excite a more rapid growth of the moss, would gradually rise above the edges until the whole surface had attained an elevation sufficient to discharge the surface water by existing channels. Springs existing under the bog would raise the surface so high as to cause it to flow over the retaining obstacle and flood the adjacent country.

The last theory as to the formation of bog from sphagnum only, I think is the most interesting, and this is corroborated by the experiments made by Mr. Joseph Boelm in the year 1875 about the fermentation of marsh and aquatic plants. He investigated the character of a large number of different plants and has come to the following conclusion. *Firstly*, that a large number of marsh plants, for example *Berula Angustifolia*, *Nasturum Officinale*, &c., if under water for any considerable time undergo a process of fermentation. *Secondly*, that aquatic plants and a large number of the marsh plants develop marsh gas. *Thirdly*, that the development of marsh gas from the decaying plants must be taken as a consequent result. This fermentation arises from unknown yet bacilli, which are very sensitive to high temperatures. *Fourthly*, the destruction of the cellulose of the plants by fermentation could be explained by the formation from one part of cellulose of three parts of carbonic acid, and three parts of marsh gas—

By this experiment the amount of carbonic acid has been less than it should be under the formula, and this is accounted for by the presence of ammonia with which a portion of the carbonic acid is combined, and *lastly*, and most important, that by a prolonged continuation of such fermentation a certain amount of turf is formed. Mr. Frey in 1879, in *Comptes Rendus* XXI., has expressed the opinion that plants have been first transformed into peat, and afterwards into coal, and that this process of transformation is the result of fermentation. I think that only upon this theory of the formation of peat from plants belonging to the family of sphagnum could be explained such facts as are known about the renovating of peat bogs. Already about 150 years ago, the Earl of Cromarty demonstrated that moss could be renovated if the bogs were cut down to the bottom and the moss peat from above filled in again, when in the course of years the bog will grow up again. Mr. De Loe who has had a very great experience at the beginning of this century in the surveying of peat bogs all over Europe has expressed his full belief in the possibility of growing up peat bogs in a comparatively short space of time.

Mr. Waggemann, in 1828, made experiments in the artificial production of peat from the plants of sphagnum, which he placed in brick tanks three feet high, filled with water, and carefully covered, leaving them to undergo fermentation, which resulted in dark brown peat the following spring.

As it is shown by the Table I, the area of the bogs which are spread over Ireland amounts to 2,830,000 acres. Of this quantity 1,816,642 acres lie in the mountains and hilly districts near the coast, and the remaining acres, viz., 1,013,358 extend across the great limestone plain, and contain almost an inexhaustible supply of peat.

In the Table I I have shown that the chief bogs are sufficiently high above the level of the nearest rivers and lakes, and therefore they could easily be drained.

One fourth of the entire superficial extent of Ireland between a line drawn from Wicklow Head to Galway, and another line drawn from Horoth Head to Sligo, comprised within it about six sevenths of the bogs of Ireland, exclusive of mountain bogs and bogs less than 500 acres. This division of Ireland from east to west is traversed by the river Shannon from north to south, and were the bogs to be divided into 20 parts, 17 of them would be found between

those lines, 12 parts west of the Shannon, 5 east of the Shannon, and of the remaining three parts, two are south, and one north of the division.

If we take the average depth of the bogs of 20 feet, which, according to the Table III., contains in the average 64 lbs. per cubic feet. We will find that each acre contains 2,700 tons, or about 7,440,000,000 tons of very dry peat is on the bogs of Ireland.

Professor Reynolds is of opinion that the stores of peat are only an asset which may become valuable when the coal beds have been exhausted after 170 years. But certainly it is in the interest of the owners of the bogs, and all the Irish people to anticipate the consequent benefit, before the expiration of such period. It is also a matter of very great importance to the prosperity of that country to utilise so serious an amount of waste land.

We find that the British Government turned its attention to this question at the commencement of this century, a special commission of surveyors having been appointed, and about 50,000*l.* spent in surveying and preparing plans of the Irish peat bogs. I do not know for what reasons, but

the further investigation was abandoned, and no practical result obtained from the very valuable reports and maps now quiescent in the Government archives.

I show here five sections of peat bogs taken by the Commissioners appointed by the English Government; the first representing a section of turf bank exhibiting marl on bog. As is seen from the drawing, in the centre of the bog there is a layer of marl, the bottom being limestone gravel. The next represents marl on the surface of the bog with the root of a fir tree well preserved. The third represents a section of two growths of trees on bog. The fourth a section of a renovated pit, showing from the other side the method of cutting drains. Regarding renovating pits, sometimes old pits and turf hill are found filled with a new growth of moss, the surface appearing to have been sunk in the centre on being deprived of its water. This new growth consists of some of the varieties of the *hipnum* and *sphagnum* and seems perfectly distinct from the original formation with which it is in contact, and in some cases is not even the same variety of plant. No part of this new formation has yet undergone the process of decomposition,

Fig. 1.

Fig. 2.

or even far advanced towards a state of decay. There are other pits in which the process of renovation appears to be going on, where the tender fibres of the convolvulus are spreading like a green film on the surface of the stagnant water. This, by interweaving with other aquatic plants may form a receptacle for the deposition of the light seeds or mosses which are blown about in abundance at the shedding season.

Figure 3 is a section of turf bank representing three distinct growths of trees. This bog is 12 feet high, and the lowest part represents the roots of trees based on limestone gravel. Above these roots is about 4 feet of compact black peat or strong turf. This constitutes the best and most durable fuel, is very hard, and has a high specific gravity. Above this black peat you will see roots of fir trees again well preserved. Beyond these we have another 4 feet deep

Fig. 3.

Fig. 4.

blackish peat or turf, and, further, roots of young fir trees, on the surface of which exists a layer of moss grasses. The fir roots and trunks possess a high degree of inflammability from the resin they contain, and when dried are used by the peasants in place of candles.

The question presents itself is peat advantageously convertible for industrial purposes? If we turn our attention to the development and use of peat in Europe, we discover that it is used in very great quantities in different industries. Already in 1856 in Germany the Aldenburg Iron Company was established and has consumed not less than 20,000 tons of peat per year, and notwithstanding coal existed in the immediate neighbourhood, and very profitable results

followed. Not far from the works of this company, in 1873, another company was established for steel manufacture by means of peat charcoal. Further, we find that in 1890, 27 glass works in Germany used peat fuel, one ton of glass consuming eight tons of peat. A Mr. Peuch at Berlin said that one ton of ready-made bottles (1,600 ordinary wine bottles) required only  $2\frac{1}{2}$  tons of peat dried in the air; or if we take 1,000 sods of peat as equal to  $3\frac{1}{2}$  tons, we find that one ton of bottles required 700 sods. A glass-melting stove with eight pots having a charge of 100 kilos, each, consumed  $4\frac{1}{2}$  tons of peat per day. In Bavaria about 60,000 tons of peat are used annually as fuel for railway locomotives.

In the report prepared by the Russian Government for the Exhibition of 1893 at Chicago, certain figures are given about the utilisation of peat for different manufacturing purposes; and we find for 1890 the following industries

have used peat as fuel, viz., the cotton manufacturers have consumed 537,000 tons; sugar manufacturers, alcohol manufacturers, confectioners, flour mills, and macaroni manufacturers, 70,000 tons; chemical manufacturers, 5,000

Fig. 5.

tons; candle, tallow, and leather manufacturers, 4,000 tons; wood-workers, 1,000 tons; tael manufacturers, 60,000 tons; glass manufacturers, 80,000 tons; paper manufacturers, 12,000 tons; miscellaneous manufacturers, 2,000 tons; aggregating approximately 772,000 tons. In addition, the Oural mines used 60,000 tons and the railway companies 15,000 tons, with prospectively an increased demand, proving conclusively the value of peat as fuel.

The use of peat for moss litter has greatly increased both in England and on the Continent during the last few years, and forms a most important branch of the industry. It is also largely used in Russia and on the Continent for earth closets and other sanitary purposes, for which, from its antiseptic properties, it is especially suited. These properties are also utilised for the preservation of fish, meat, and eggs in transit, and its non-conducting properties have rendered it useful for the preservation of ice. Lately attention has been paid to the utilisation of the fibres of the top peat for making paper-pulp, felt soles, and in substitution for shoddy in the manufacture of horse-clothing and other cheap cloths.

Professor Reynolds in his paper showed that peat in its ordinary condition is a very bulky fuel, occupying more than five times the space of an equal weight of coal; that it contains from 15 to 25 per cent. of water and seldom less than 10 per cent. of ash, and that at least 2½ lb. of Irish peat is required to perform the same work as 1 lb. of Staffordshire coal in an ordinary fireplace or furnace. All these disadvantages could be easily removed by more careful treatment of the peat itself. Reduction of the bulk and the removal of the water could be done by partial carbonisation.

Carbonisation of peat is a very old question, and generally speaking can be described under the following heads:—

*First*, carbonisation in heaps.

*Second*, in closed ovens of brick and iron in which the peat is lighted, and after it has sufficiently formed a good flame the oven is closed, air excluded, and the carbonisation goes on.

*Third*, the carbonisation in closed retorts heated from the outside.

*Fourth*, carbonisation by superheated steam.

*Fifth*, carbonisation by burnt and consumed gases.

*First*, carbonisation by heaps. As early as 1712 Mr. Carlowitz in his "Sylvicultura Economica" proposed to carbonise peat in heaps, but no important steps appear to have been taken until 1836, when Mr. Schmidt introduced it into the Lavariao State iron manufactories. This method was to pile up heaps of 2,500 cubic feet capacity; the quantity of peat carbonised was stated to be 13½ tons, and the amount of peat charcoal obtained 3 tons 8 cwt., or 25·2 per cent. The carbonisation of such heaps and the cooling down required about 12 to 14 days.

*Second*, in closed ovens. The oldest and best known oven has been constructed by Mr. Lange in 1745. As it is seen from the drawing, this oven consists of a square foundation (a a) on which an iron plate (b b) is placed, in which (b) a square hole of 15 inches is made; (c) is the grate, which is closed by a door. On the plate is based an iron cylinder (d), above (d) a second one (e), and above (e) a conical stone (f) is placed with an opening (g) 16 inches diameter.

In 1767 an oven of new construction was built on a round foundation of 17 feet diameter, and from 2 to 4 feet high,

on which has been placed a round brick cupola of 16 feet exterior diameter, and 4 feet thickness. In the centre of this cupola a cylinder of 6 inches diameter has been built up filled with sand and ashes. At a height of 13 feet, the oven finishes with an opening of 4 feet diameter. Both ovens, however, proved a failure. The peat lying above crumbled down the charcoal formed below it, and to avoid this Mr. Hahnemann proposed the following construction as seen by the drawing. A round cupola of 16 feet high and 7 feet diameter, with a thickness of the walls of 2 feet at the bottom and 10 inches at the top, on the foundation the grate (*f*) is placed, and connected with an opening (*k*) for taking out the charcoal. At the commencement of the charring, the opening (*k*) is closed, and the cupola is filled up with peat and fired from the top. When the peat has commenced to burn sufficiently, then the top of the opening of the cupola (*a b*) is closed, and thereby the gases produced are bound to pass down through the mass of the peat and through the opening (*f*) and pipe (*g*) from the retorts. The products

Fig. 6.

FIRST PEAT OVEN CONSTRUCTED BY LANGE, 1745.

of this distillation are condensed in the condenser. When the fire in the cupola has come down nearer to the opening (*f*) all the openings are closed and the stove is left to cool down.

On the same principle is based the stove of Moreau, Père and Fils, a model of which has been exhibited in the Paris Industry Exhibition in the year 1855. This apparatus consists of a cylinder of sheet iron eight feet in diameter and the same height, such stove carbonising in 24 hours three tons, and producing 40 per cent. of charcoal. In 1851 a special process was invented by Mr. Reece, in which process the British Government took very great interest, and appointed a special commission to investigate with a view

to establishing profitable peat industries in Ireland, and the Irish Peat Co. was then formed. A site was chosen in the

PARIS EXHIBITION OF 1855.

Great Southern and Western Railway, while on the other side runs the navigable river Barrow and the canal to Dublin and Waterford. 500 acres of very excellent bog land were taken on a lease for 100 years at a rent of 5s. per acre. Mr. Scanlon, chemist, was sent by the Company to make experiments. He commenced working the furnaces at low temperature, and distilling the products by steam. From the information supplied by the Company it seems that from 100 tons of peat were received—

	£	s.	d.
1 ton of sulphate of ammonia .....	12	0	0
½ ton of acetate of lime .....	9	10	0
50 gallons of naphtha .....	12	10	0
300 lbs. of paraffin .....	15	0	0
300 gallons of volatile oils .....	15	0	0
	61	0	0

these being current value at the time. Cost of production of peat, acids, labour, etc., 32*l*.

The last practical attempts, so far as I know, were made in the year 1880. A company was formed in the name of the West of England Compressed Peat Co., which constructed 12 ovens for making peat charcoal at Rattlebrook on the slope of one of the highest hills of Dartmoor, nearly 2,000 feet high. The process which was adopted by this company was the invention of Mr. Kidd. The principle of his invention was the introduction of a jet of superheated steam, but nothing came of the scheme. The Duke of Sutherland was the first to take up Kidd's process, and in 1874 an experimental plant was erected on his estate in Sutherlandshire. The peat here is of very dense quality like the Dartmoor peat, and contains a large amount of hydro-carbons.

From this short description of the processes introduced for the utilisation of peat in one way or the other, it will be seen that most of the inventors have only had one end in view, whereas to gain a real practical success, we must work in the same sensible manner as we do with all other products. Most of the inventors have striven to produce only peat-charcoal, not taking notice of by-products which could be and should be received in course of charring, or they have concentrated their attention on the by-products without regard to the charcoal.

TABLE II.

## ANALYSIS OF PEAT.

In my investigation I have first tried to avoid all the conditions under which any of the constituent parts of the peat would be destroyed. I have applied in this the same principle as I have adopted in the destructive gasification of oil and of coal. This means using a very low temperature, and gasifying in the presence of an inert gas which could not have any chemical influence on the substances received, but which would have the mechanical effect of extracting all the by-products and leaving only pure charcoal in the retorts.

The apparatus with which I propose to treat the peat, consists, as you will see from the drawing, of two or more chambers or retorts, in which the peat is placed. The chambers or retorts are heated externally by generator gas from a furnace (*d*). The inside of the retorts or chambers is heated by water gas produced in a furnace (*k*) and passing to the upper part of such retorts. This water gas, which is admitted into the retorts at a temperature above the initial heat of the interior of the retorts, mingles with the matter under treatment, and rapidly separates the volatile constituents, which are conveyed from the passage (*m*) through the pipe (*o*) and then into the condensers in which the liquid by-products are condensed.

The charcoal contains 4.23 per cent. of ash. The liquor contains an average of 5.89 per cent. of tar, and 35.7 per cent. of water solution. The specific gravity of the liquor

is 1.0135. 100 cc. of the solution contains 0.2344 grms. of ammonia and 2.16 grms. of acetic acid.

From the Table 2, which is a result of 13 analyses made by my assistant Dr. Fuerst (to whom I now take the opportunity of expressing my thanks) I have received such results as applied in practical form will give the possibility of developing a large chemical industry in Ireland. The peat used for this analysis was sent down to me from Barrow in Furness, and was sufficiently dry. But to obtain a fairer sample and a practical knowledge of the peat bogs themselves I made a special journey to Ireland in April last, and after careful investigations took samples representing both lowland and mountain bogs. The first range of samples which I took (lowland) were from the estate of the Earl of Longford. This estate is situated at Killuenn, with the Royal Canal on one side and the railway on the other, and contains about 11,683 acres, which mostly consist of peat bogs. On this estate are about 340 tenants, who cut the peat for fuel, and afterwards reclaim the land. I also take here the opportunity of thanking the manager of this estate, Colonel Clark, for his kindness in showing me such a well conducted estate. He has been for 19 years fighting hard with the object of reclaiming the peat land for agricultural purposes, with splendid results, of which he has reason to be proud. From the view shown to you you will see that a large number of trees have been planted by him

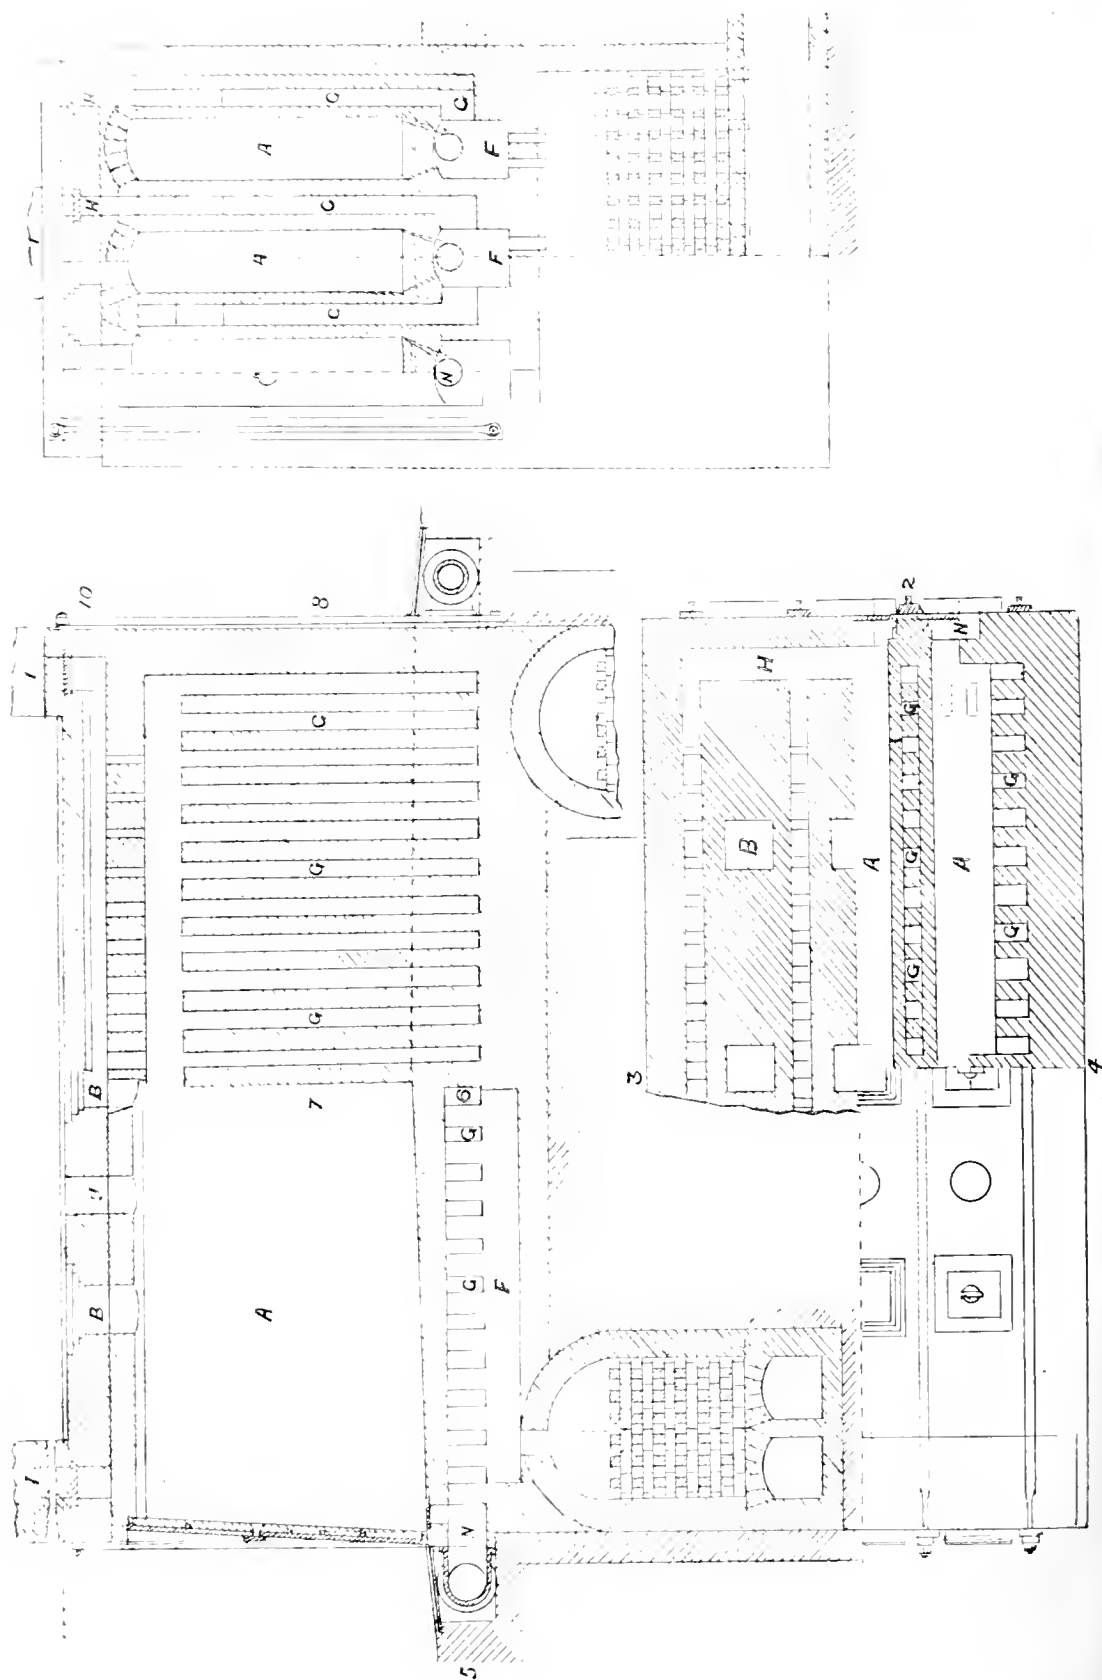

Fig. 9.

PEAT OVEN FOR RECOVERING BY-PRODUCTS.

\* Dyer's patent.

Fig. 10.

SECTION OF PEAT OVEN FOR RECOVERING BY-PRODUCTS.\*

on the peat bogs. It is true that the work demanded a large expenditure of energy, especially during the first years, but the results are so satisfactory that I am sure the gallant Colonel will never regret the pains taken, nor the owners the expense. The trees on the sides of the bogs are doing very well, but those planted in the centre do not thrive so well,

on account of the excess of moisture. The other samples, which represent the mountain peat, were taken from the estate of Mr. Atkins, at Dunmanway, County Cork. This peat is much blacker than the peat from the North. The difference between the top and the bottom peat is not so great, and the top peat has not the elasticity which we have seen in the case of Killucan. In such cases this peat should be used for distillation purposes only, but when we have the top parts light coloured, I think it would be more practical to treat them separately and prepare from them very valuable moss litter, leaving the lower layers for distillation.

From the results shown in the Table III, you will see that I have taken care to have a fair sample of the peat bog as it is. I have taken a section from the top to the bottom, so that my analyses represents the real nature of the peat. The higher strata has a lighter colour, which is chiefly due to the fact that it is not sufficiently decomposed. The main constituent of this top part is the real moss which is very elastic and like a sponge, having the quality of holding a large amount of water, the most of which you could press out by hand, after which the moss regains its original form and volume. When dried in the air, or artificially, it does not form hard lumps, but always remains soft and elastic. The analysis shows that whereas the volume of the lower layers has been reduced more than one half after drying, the volume of the top has reduced very little. The lower peat is generally very much decomposed, and after drying has not the property of reabsorption, whereas the top section will absorb the same amount of water which they previously contained. These results are in accordance with those obtained by Professor Fleischer, the director of the German official peat investigation station at Bremen.

As it is seen from the analysis, the difference between the low land peat and mountain bogs is chiefly in the producing of more charcoal. The quantity of other products is less than in lowland bogs, and I think that is mainly due to the physical condition of the top part of the bog. Whereas the top part at Killucan is very porous and elastic, and therefore the absorption of ammonia from the air is great, the top part at Dunmanway's bogs do not differ from the bottom part. But in the average the difference is very little.

The distillation of peat for by-products is not a new idea. It was proposed long ago, but, unfortunately, for the reasons already explained, the industry has not flourished. The production of mineral oil and paraffin from peat was established in 1889 in Brazil at Marabá. In the Journal of the Society of Chemical Industry there is an account of this establishment, which was producing not less than 80 tons per month of solid paraffin for candle-making. What is very important for the practical establishment of such industry is the treatment of peat before distillation.

The analysis shows that the peat as originally won contains from 85 per cent. to 93 per cent. of water, which when pressed out is found to contain in solution salt, and therefore it is very important to squeeze out as much as possible, as thereby the amount of ashes in the charcoal will be reduced. We have certainly in the market a great many different systems of compressing machines, and I am quite sure that the English engineers will soon find out the best means for compressing out this large amount of water at a cheap price. Apart from this, special attention must be paid to the drainage of the peat bogs themselves. If the peat bogs are not properly drained, as very often is the case, the amount of work necessary for cutting and drying is increased tremendously. At the same time you must always bear in mind that in draining off the water it is necessary to leave a sufficient amount to keep the lower parts in a sufficiently spongy state. This, however, is not a place to explain all the necessary conditions under which peat bogs must be worked, nor have I gained sufficient practical knowledge to warrant my advising upon the best methods of cutting and drying. My researches have been directed to the treatment of the industry from a chemical point of view, and I certainly think there is something to be done, and I am also sure that painstaking work will show fresh means of treatment, and larger openings for products obtained.

The CHAIRMAN, before inviting Dr. Dvorkovitz to read his paper, said they were very glad to see amongst them that night an eminent foreign chemist, one of their own members, in the person of Dr. Menéndez.

#### DISCUSSION.

Mr. BOVERTON REDWOOD said he did not know that he could say much that was novel in connection with this paper, but it appeared to him that the author had hardly given sufficient attention to the work which had already been done in connection with the utilisation of peat in Ireland. Though he was very loth to damp the ardour of Dr. Dvorkovitz, especially when he had such a laudable object in view as the amelioration of the condition of Ireland by the introduction of a new industry, yet it would be undesirable to raise up hopes which were never likely to be realised. It was well known that as long ago as 1849 Mr. Reece Rees patented a system of peat-distillation, and in 1851 the results obtained in the practical application of that system were very carefully investigated by Sir Robert Kane and Dr. Sullivan. The process consisted in distilling the peat in a kind of blast-furnace of brick encased in sheet-iron, somewhat similar to an iron blast-furnace, but with an arrangement at the top for taking away the products of distillation and conveying them through scrubbers and condensers. The furnace was about 10 ft. in diameter, and took a charge 100 tons. The charge having been lighted at the base, a current of air of about 3,000 cub. ft. per minute was introduced, and the distillation was effected by the heated gases produced. At the expiration of 24 hours the operation was completed, and Mr. Rees claimed that the ash underwent a species of fluxing, and came away as fluid slag. The products consisted of gas, an aqueous liquid, and tar. He professed to obtain from 100 tons 6,000,000 cub. ft. of gas containing hydrocarbons, a certain amount of free hydrogen, carbonic oxide, and some carbonic acid. The aqueous liquid contained ammonia, and from the tar lubricating oils and solid paraffin were obtained. Sir Robert Kane and Dr. Sullivan found great difficulty in carrying out the process described in the patent specification. According to their report, if the blast of air was sufficiently strong to give a combustible gas, there was practically no tar distillate, and, on the other hand, if they moderated the air-blast so as to get a fair yield of tar, they did not get the combustible gas. In fact, under the best conditions they found it exceedingly difficult to obtain a gas which could be used as fuel, and that was practically the basis of the process. Mr. Rees asserted that out of the 6,000,000 cub. ft. of gas which the 100 tons of peat produced, 2,000,000 would be sufficient to supply all the fuel necessary, and the remaining 4,000,000 would be available for use in lime-burning and various other industrial operations. But as a matter of fact, the outcome of this investigation was not confirmatory of the statements made, and was altogether of a very discouraging character. In 1861 Dr. Paul worked at the subject for Sir James Matheson, and obtained satisfactory commercial results, the balance sheet representing a year's working, showing a very fair margin of profit. It must, however, be borne in mind that at that period both the oil which was obtained and the solid paraffin fetched very much higher prices on the market than they would at present, and it seemed difficult to understand how it was possible, looking at these products as a source of income, to establish any profitable industry in connection with the distillation of peat. It might be that when they had the paper fully before them, and could understand a little more clearly the principles upon which the author was proceeding, they might be led to form a more favourable opinion of the prospects of the undertaking. It was possible that a modification in the method of working might give more favourable results than any hitherto obtained, but the difficulty would always remain that peat was of an exceedingly variable character. In the 27 samples of peat which were examined by Sir Robert Kane and Dr. Sullivan, there was an enormous variation in the physical and chemical characters. To give only one example, the highest specific gravity was 1.058, and the lowest 0.235, the density of the greater number being below 0.6. With

a material varying so greatly, it was very difficult to form a definite opinion as to the results to be practically obtained. Dr. Dvorkovitz had exhibited courage in taking up a subject which was certainly not of a promising character, and he should be only too glad to congratulate him if the outcome of his investigations was the establishment of a new industry tending to benefit Ireland.

Mr. WATSON SMITH said he had listened with great interest to this paper. Possibly Dr. Dvorkovitz would be interested to know that his friend the late Dr. R. Angus Smith read a most valuable treatise on this subject, which was unfortunately buried in the archives of the Literary and Philosophical Society of Manchester, and he would therefore give a summary of the results arrived at by Dr. Smith. He took a comparatively modest view of the possibilities of utilising peat. Speaking of the varieties of the substance, Dr. Angus Smith said that when anyone mentioned "peat" it was essential that he should define the kind of peat he referred to, so great are the differences. Mr. Boverton Redwood had shown this in speaking of the wide divergencies of specific gravity. Dr. Angus Smith states that a cubic foot of the more porous variety weighed 4 lb., and one of the lightest kinds from 48 to 80 lb. Certain peats contained a considerable quantity of bitumen soluble in benzene. In heating effect approximately  $2\frac{1}{2}$  parts of dry peat were equal to 1 of coal, whilst  $2\frac{1}{2}$  of dry woody fibre were equal to 2 of coal. Dr. Angus Smith stated that he could imagine—and on this point he laid great stress as regards benefit to the Irish peasant—farms of no great size growing fuel as fast as it could be used by a limited population, and even giving oil and ammonia by distillation and compression. It was pointed out that peat, or rather the growing peat, *i.e.*, peat-moss, always flourished best on a surface of its own kind, and therefore when a peat-bog was cut, the upper living surface ought to be carefully preserved, and immediately replaced on the cut surface, and in that way the surface plants (*sphagnum*) went on growing, and thus peat might be preserved and cultivated. With regard to the nitrogen and the quantity of ammonia to be derived by distillation, sometimes 2.4 per cent. of nitrogen, and occasionally 2.5 per cent., was found in dry peats. Certain peats, however, contained as little as only  $\frac{1}{2}$  per cent. Dr. Angus Smith thought it extremely likely that ozokerite was derived from oils which originally flowed from Austrian peats. Such oils had, indeed, been found under a large heath in Germany, the Luneberger Heide. On distilling the peat, oils and waxes were obtained, and several experiments showed a yield of as much as 6 per cent. The late Professor Schorlemmer had an opportunity of examining some of these oils, and found that they contained paraffin. It was curious that an oil from the heavy peat from Stornoway, when boiled with caustic soda, nearly all dissolved, and the solution on acidification yielded a resin closely resembling shellac in appearance. Dr. Angus Smith further suggested the utilisation of the living peat for storing water, because of the immense quantity absorbed and retained, as much as 75 per cent. of water being held in some peat-bogs over which animals and men could walk. It was certainly a novel and original idea to grow a water-reservoir, as Dr. Angus Smith had quaintly suggested, on the side of a hill, instead of digging one! In cutting a 10-ft. bog, we may allow by shrinkage one-fifth to remain dry. Such a bog, 10 ft. deep, will hold as much water as a reservoir of the same dimensions  $7\frac{1}{2}$  ft. deep. There was no doubt that before peat could be distilled in ovens like those proposed by Dr. Dvorkovitz, it would have to be compressed and dried, and probably be charged in in blocks. With ovens in construction so generally resembling the Otto-Hofmann coke-ovens, a very high temperature might be expected, and he presumed the gas used in firing would be the return-gas derived by the distillation of the peat. By distillation of a fuel containing so much woody fibres and matters akin thereto, under such conditions, it would be highly interesting to know what the characters of gas, tar, and aqueous residual would turn out to be. He at present, and in absence of distinct data, suspected there would not be anything like gas enough of a heating and inflammable kind, furnished, to keep such ovens going.

The CHAIRMAN said he did not know whether the peat-bags of Ireland, of which there seemed to be not only plenty, but a perennial supply, would come into immediate use while coal was to be had at anything like its present price, but the day might come when coal would be a costly article, and they might be obliged to resort to peat. In any case the collection of such information as that of Dr. Dvorkovitz would be of great value.

Dr. P. DVORKOVITZ said Mr. Redwood had expressed the belief that the treatment of peat could not be made practicable, and had supported it by the valuable report of Sir Robert Kane and Dr. Sullivan, but he thought he would admit himself that the admission of air into the retort was sufficient to account for the failure, as it prevented the production of any oil. It was no wonder, therefore, that the Rees process had failed. He was quite satisfied that if Sir Robert Kane and Dr. Sullivan had been more careful in taking their samples they would not have come to the conclusion they did as to the immense variety of peat. He had taken samples on the spot, which he had put in waxed paper and then in brown paper, and after bringing them home he found that 15 per cent. had already evaporated. He had analysed 17 samples of this peat, and nearly all, excluding only the top layer, gave the same results upon distillation. The samples should be weighed as soon as cut, and then you could tell whether they were different or not. Some samples when gradually dried in air would lose 75 per cent. of their weight, and of course all these points had to be allowed for in determining the specific gravity. He was not aware of Dr. Paul's experiment in 1861, though he had read a great deal on the subject. In fact there was too much written about peat, and at the same time too little. Generally peat had been treated very badly. The geologist did not want to know about it, or the botanist, and most of the books he had read had been written by reverend gentlemen. With regard to the practicability of using peat, he would remind them that it was found very practicable in Scotland to treat shales and obtain only 12 per cent. of oil and a certain proportion of ammonia. The quantity of ammonia in peat was tremendously large, and he thought it could be increased artificially. Peat absorbed ammonia very largely, as was shown by experiments made by Professor Fleischer and Dr. A. König. It had such great affinity for ammonia that if you put peat into carbonate of ammonia you would find after two days a large quantity of the ammonia was absorbed by the peat. Surely if it was worth while to distil shales for 12 per cent. of oil and a certain amount of ammonia, it was equally worth while to distil peat if you could get 6 per cent. of oil, 40 per cent. of charcoal, which was very valuable, and the ammonia would be not less than in the shale, apart from which you had acetic acid. He did not see why such prejudice existed against it, and why so many people believed that this business could not be established. When he went to Ireland he was told it was no use wasting his time about peat; lots of people had tried it already and failed. But if 99 had failed he wanted to be the 100th, who would succeed. If the members of the Society would pay more attention to the matter he was quite satisfied something could be done. People were quite ready to invest their money in Australia to find gold mines, but if they found them lying at their own feet they did not care about them; they are too near to them. It would be a great pleasure to him if he could see more attention paid to this matter, and the process of distillation established for the sake principally of the by-products, which he was sure would be practicable.

Mr. BOVERTON REDWOOD asked leave to add one word in justice to Sir Robert Kane and Dr. Sullivan in reference to the concluding remarks of Dr. Dvorkovitz. They did, as a matter of fact, make some comparative experiments also in the distillation of peat in closed vessels without an air-blast, and he believed he was right in saying that the results which they thus obtained were substantially the same as the best of those yielded by the application of a moderated air-blast.

Dr. DVORKOVITZ said he should have explained that he was aware of these results, and he did not wonder that they

were not more favourable. In distilling peat in closed vessels without squeezing out the water, you must use a large amount of heat to distil so much bulky material, and this large amount of heat used in closed vessels abstracted a large amount of the oily matters and a large amount of gas—much more really than that used.

The CHAIRMAN said, as this was the last occasion on which he should occupy the chair, he wished to express in a very few words his sense of the honour which was done him two years ago in electing him to the office of Chairman. From that time he had been very sensible of his own short comings, but he would be ungrateful if he did not thank those who had so ably assisted him—the Secretary, Mr. Heron, the members of the Committee, and the members of the Section at large.

The name in italics is that of a Member of Committee that retires at the end of the current session.

The following has been elected to fill the vacancy, and will take office in July next:—Committee: W. Thomson.

Meeting held Friday, 1st June 1894.

MR. IVAN LEVINSTEIN IN THE CHAIR.

### PRESENTATION TO MR. J. CARTER BELL.

THE Chairman said that before proceeding with the ordinary business of the meeting they had a most pleasant duty to perform. About ten years ago Sir Henry Roscoe had expressed an opinion that there was not material for the establishment of a section in Manchester, and that there was not sufficient interest taken in matters connected with the chemical industries in the neighbourhood at that time to ensure success. But owing to the great zeal exerted by their hon. secretary, Mr. Bell, during this long period of ten years the Section had grown to be one of the most important in connexion with the Society of Chemical Industry. Not only had the meetings been the means of imparting much valuable information to the members, but the social meetings, which had been organised by Mr. Bell in connexion with the Chemical Club, had also formed and cemented friendships which otherwise would never have existed. In acknowledgement of the very valuable services thus rendered by Mr. Bell at a great sacrifice of time and labour, and also in appreciation of his high professional

gratefully received with pleasure in presenting to him on behalf of the members of the Manchester Section of the Society of Chemical Industry, and of the Manchester Chemical Club the testimonial now before them, and in doing so he hoped Mr. Bell would enjoy the gift for many years to come.

The testimonial consists of an English brass quarter-line clock, on gongs and bells, with brass vases to match; also a pair of brass pedestal oil lamps. The clock bears the following inscription:—

"Presented to J. Carter Bell, Esq., A.R.S.M., F.I.C., by the members of the Manchester Section of the Society of Chemical Industry, and of the Manchester Chemical Club, June 1st, 1894."

Mr. BELL, in acknowledging the presentation, said it was not easy on such an occasion to express his feelings, but he assured them that he really felt they had done him a great honour and he was exceedingly grateful to them for the magnificent gift. Mr. Levinstein had been too modest in not taking credit to himself for being the first to suggest the formation of the Chemical Club, which had strengthened the Section, and so Mr. Davis must be given the credit of starting the Section, as well as the parent Society. Mr. Levinstein and Mr. Davis had planted, and he (Mr. Bell) had only watered. He could only add that the work he had done had been a labour of love. Of the 30 years he had been in Manchester the last ten had been by far the most enjoyable and profitable, and any services he had rendered had been amply repaid by the many friendships he had formed.

## COMPARATIVE RESULTS OF SOME MODERN SYSTEMS OF SEWAGE TREATMENT.

BY W. NAYLOR, F.C.S.

### DISCUSSION.

THE CHAIRMAN thought it would be desirable to avoid any reference to the way in which analyses of sewage were obtained, in view of the contemplated action of the Mersey and Irwell Committee against the Salford Corporation. Sir Henry Roscoe, M.P., chemical adviser to that committee, and Mr. Scudder, his assistant, had been invited to attend the meeting, but found themselves unable to do so. Sir Henry had written saying that it seemed to him that the materials incorporated in Mr. Naylor's paper were insufficient to base any definite proposals upon for the treatment of sewage, and both he and Mr. Scudder submitted that any conclusion to be satisfactory must be based on average, and not on single results. Mr. Scudder had sent the following communication on Mr. Naylor's remarks upon the electrical process.

MR. SCUDDER wrote as follows:—I very much doubt the propriety of entering into a discussion of a paper of this kind. It was said to be one on the comparative results of some modern systems of sewage treatment, but I venture to think that it is nothing of the kind. The table of results is far from satisfactory, and not at all suitable for drawing any recommendations therefrom. No one will, I hope, think of suggesting a line of action on a single experiment, and on the incomplete data given in the table of results. With reference to the scientific portion of the paper I should like to know why in considering two such abortive chemical equations as given by the author we must bear in mind that "ferrie hydrate is only sparingly soluble in water"? Mr. Naylor raises a question as to the cost of the electrical process based on the contention that additional electric energy will be required as the iron plates become thinner to compensate for the assumed increase of resistance caused by the increased space between the plates. Now, I have had the advantage of discussing this point with Mr. Octavius March, the electrical engineer who superintended the electrical details at Salford, and he contends that no additional

electrical energy will be required, but on the contrary, up to a certain point at any rate, there will be a reduction rather than an increase of total resistance. An electrolyte as a conductor is *not* comparable with a metallic conductor. If the resistance of a given length of a metallic conductor of uniform section be  $R$ , double the length will have a resistance of  $2R$ . But the portion of the electrolyte contained between two plates is *not* analogous. The passage of the electric current is *not confined* to that part of the electrolyte only; consequently if the specific resistance of electrolyte between two plates  $\frac{1}{2}$  in. apart be  $R$  the resistance when such plates are placed 1 in. apart will *not* be  $2R$ . By experiment it has been found that when the resistance between two plates  $\frac{1}{2}$  in. apart is 3, at 1 in. apart it is 4, not 6. The specific resistance of a given electrolyte is governed by three factors:—

- A. The area of electrodes immersed.
- B. The distance between the electrodes.
- C. The total bulk of electrolyte employed.

The first two are apparent. The third may be shown by taking a pair of electrodes fixed together at a given distance and immersing them in the electrolyte, in a vessel just large enough to take them. Note the current passing and the potential employed.

Then immerse them to the same depth in a larger vessel containing similar electrolyte, using the same potential, and it will be found that a larger current passes, thus showing a diminution of resistance.

The specific resistance of electrolyte is only a small factor in the calculation required to ascertain the E.M.F. necessary to obtain a given current through a given cell.

The arrangement of the Salford plant was such that the total resistance of each cell was 0.002 of an ohm—of this, about half would be represented by resistance of conductors and contacts, leaving 0.001 as the specific resistance of electrolyte. The mean counter E.M.F. was found to be 0.8 of a volt.

With the current to be employed a potential of 0.33 per cell would be required to overcome the specific resistance of the electrolyte. The same to overcome the resistance of conductors and contacts and 0.8 to balance the counter E.M.F. This gives us 1.46 volts as the total E.M.F. required per cell.

If the space between the plates were doubled, all other conditions being maintained, the resistance 0.001 would be increased to 0.0013, and the E.M.F. required to overcome it would then be 0.438. This + 0.33 + 0.8 gives 1.568, an increase of about 7 per cent.

With the arrangement proposed the space between the plates *could never be doubled*. The plates being  $\frac{1}{2}$  in. and the spaces  $\frac{1}{2}$  in., if the plates were reduced to their centre line, the space would only be increased from 5 to 9.

The dissolving action on the iron does not reduce it uniformly over the whole surface, but tends to pit it, converting a comparatively smooth surface into an increasingly rougher one and so materially *increasing* the surface of iron exposed. A square foot of iron plate  $\frac{1}{2}$  in. thick, would have a surface on one side of 144 square inches. If 96 holes 1 in. diameter were bored in this plate, the area of such holes would be 72 sq. in. and the remaining surface of iron also 72 sq. in., but the area of the sides of each hole would be 12 sq. in., so that the surface of iron exposed would be increased from 144 to 222 sq. in.

If the holes were bored  $\frac{1}{4}$  in. deep instead of through the plate, the exposed surface would be increased to about the same extent, viz., from 144 to 219, an increase of more than 50 per cent. This increase of surface would therefore more than compensate for the increased mean distance between the exposed surfaces. (For convenience in this calculation I take the area of the circle to be diam. 2.75 instead of 0.7854 and the circumference to be diam.  $3\frac{1}{2}$  instead of 3.1416).

With reference to the weight of iron that may be regarded as available, it is impossible to do more than estimate this. From a careful examination of the plates that were in constant use for some months at Salford, Mr. March came to the conclusion that  $\frac{2}{3}$ ths of the iron might be used, but as

a matter of fact in all the calculations, and estimates a loss of  $\frac{1}{2}$  was assumed in order to be on the safe side.

I have dwelt rather lengthily on this question because it is most important to point out the injustice that is caused by writers of papers not fully investigating the work of others and asking for their help, before they attempt to discuss questions about which they have no intimate knowledge, and levelling criticism of an order not calculated either to assist materially in the solution of the sewage problem or to aid those who have had sufficient energy and willingness to embark on the financial path of the problem.

Mr. BELL said he quite agreed with Sir Henry Roscoe and Mr. Seudder that the results obtained by Mr. Naylor were only isolated results, and must not be taken as conclusive. Mr. Naylor had referred to the amines process and, according to his analysis, the process gave no purification. They had treated 10,000,000 gallons per day at Salford on the Amines system and a very clear effluent was obtained. This, in his opinion, was principally due to the large excess of lime, from 20 to 30 cwt. being used to the million gallons. Of course the effluent would be very alkaline, but would keep better than salts of iron effluents. Unfortunately all lime effluents possessed a most peculiar odour, and they were said to decompose much sooner than others. To form an opinion of any process it should be tried week by week and month by month, as in the case of the Salford experiments. If he found a process which would give effluents containing 0.2 down to 0.1 of albuminoid ammonia in the 100,000 parts, he should call that a very good process, and above all he must emphatically say it was not so much the amount of albuminoid matter in the effluent, but its liability to secondary decomposition.

Mr. GRIMSHAW said, in common with Mr. Carter Bell and others, he had gone pretty extensively into the question of sewage purification, and he was bound to say that he agreed generally with his remarks on Mr. Naylor's analyses. At the same time, he did not suppose that Mr. Naylor intended to say that it was an exhaustive *resumé* upon sewage matters generally, but that it was a contribution intended to assist an accurate knowledge of the purification of sewage. He could supplement Mr. Naylor's figures as regards the iron treatment at Horwich, where Mr. Naylor gave a certain figure on a particular day. On referring to his book he had found an odd result which agreed with Mr. Naylor's figures. Speaking from memory, he believed Mr. Naylor obtained 0.4 in the effluent. Taking a long series of figures, it appeared that the process averaged out 0.2 to 0.28, and in these figures there was 0.4 for the highest and 0.2 for the lowest. With regard to what Mr. Bell had said in relation to lime treatment, they knew that if plenty of lime were put into sewage a good-looking effluent resulted, and in many cases that effluent would not decompose afterwards. On the other hand, it very often did and was sometimes worse than before treatment, hence the lime treatment, *per se*, stood universally condemned. In such a process as that of the Amines, involving the use of 40 cwt. of lime per million gallons, which, converted into carbonate, would give something like 11,000 tons of sludge per annum in the case of Salford, independently of the sewage residuum itself, he supposed that no river authority would allow such an alkaline effluent to be run into a water-course. They would have also to consider that the cost for lime would make it a very dear process. In regard to the experiments at Salford, the trials there had given a vast store of information which, although very ill digested, had been very useful to sewage chemists. Whilst Mr. Bell had put the question very neatly as to the experimenters who had been there, he did think that in one or two cases the Salford Committee had made mistakes, in so far that they expected the experimenter to become familiarised with all the conditions of a huge sewage works in a week or two, and expected them to produce in about a fortnight a result sufficiently satisfactory. That was to say, they asked these experimenters to do in three weeks what the corporation themselves had failed to do in six or eight years. In fact, the experiments had been suspended just when they were beginning to be successful. With regard to the question of after decomposition of sewage effluents and manufacturers'

effluents, it was not necessary for all to be skilled bacteriologists and to determine as to the exact germ to which the decomposition was due. For instance, the water of the Irwell, in consequence of the chemicals turned into it, was unable to putrefy during its flow, but anyone who knew anything about the Ship Canal would observe the fermentation which was taking place there. The point after all which had to be taken into consideration in the application of sewage treatment was whether the effluent would be one which would not be dangerous to health. He thought it would be more profitable if chemists would bear that fact in mind. They had been led into error by giving too exclusive attention to albuminoid ammonia. They wanted more facts in relation to other impurities. He believed much good might be done by sewage chemists comparing the results of their special tests, with a view to arrive at a conclusion as to which test or group of tests gives in the simplest and quickest way a means of deciding whether the effluents from sewage works and manufactories will afterwards become objectionable or will remain innocuous, and he hoped that the next contribution to the Society on this subject would be in this direction.

Mr. NAYLOR said in reply:—The chief ground of complaint appears to be that a greater number of results have not been presented. This is solely due to the fact that a man cannot give more than he possesses, and were it not for this unfortunate circumstance further results would certainly have been given.

At the same time, since the works on the subject, by Corfield, Slater, Crimp, Wandle, and others, and the reports of the Rivers Pollution Commissioners, the United States National Board of Health, the Massachusetts State Board of Health, and the experiments conducted by the Leeds, Bradford, London, and Salford Corporations, have one and all been unsuccessful in bringing about any approach to unanimity of opinion, I do not for a moment anticipate that any number of results compilable by a single individual would do any more good than will be done by what this paper simply purports to be, viz., a series of results representing fairly the work of some present day systems under normal conditions.

In Lancashire, at any rate, the question has been fought in the law courts during the past three years, principally upon the clause in the 1876 Act, which stipulates that an authority is not in default if he is using the best known practicable and available means. Now it appears to me that the best known practicable and available means are exactly those which result in leaving in the effluent the least amount of objectionable matter, compared with others.

By this I of course do not mean the amount of objectionable matter taken from the effluent but the amount left in. What this was to begin with, and therefore the percentage of purification matters nothing, so long as an average sewage is proved to be capable of treatment. If the sewage be unusually strong, then must the authority pay for its water carriage system with a small volume flush by double or even a triple treatment. At any rate, this much I contend, that every system must come in line with that which is shown by results to produce the best effluent under normal conditions.

I must confess that I cannot agree that the absence of secondary decomposition apart from the quantity of contained organic matter is any criterion of fitness to enter a river. The possibility of secondary decomposition depends entirely upon constantly changing conditions of chemical and bacteriological environment, and upon these grounds alone can it be discussed.

The action of lime, so far as my experience goes, is practically nil in reducing organic matters in solution. As a precipitant for suspended matter or as a clarifier, it has a good effect, but practically nothing further.

Alumina-ferric has been found to have a decolorising effect upon colouring matters if the liquor to be treated is rendered slightly acid, but no effect is noticeable with vegetable colouring matters, aniline blacks, and other aniline colours, particularly benzopurpurin.

Dealing more particularly with Mr. Seudder's criticism, I have yet to learn that financial losses incurred in the practical working of any process render such processes free from criticism, or that any *injustice* is caused by criticisms levelled by persons having no intimate knowledge of the subject matter.

In such a case criticism is likely to be more absurd than unjust: notwithstanding I claim both the financial loss and intimate knowledge with respect to a similar process, patent rights for which I took out four years ago, but which were allowed to lapse, as the working of the process was not a success from the very causes put forth in this paper.

M. Seudder's criticism is worthy of considerable merit and attention as a very ingenious contention of facts. He begins by saying that "an electrolyte as a conductor is not comparable with a metallic conductor," and, as he makes no allusion to the reference I gave which shows that it is comparable, I must take it that he claims a difference due to his statement that the passage of the current is not confined to that part of the electrolyte only between the plates.

Now, one may perhaps follow his comparison of similar electrodes at similar distances apart in differently sized vessels, and may perhaps even admit that the current may pass through some portion of the electrolyte other than between the plates in the large vessel, but in the case of Salford the electric shoot was completely filled with electrodes, and it was really absolutely impossible for the current to pass anywhere else than between the plates.

The channel was 90 ft. long, and full from end to end with electrodes, which at any point were not more than half an inch apart; and since they were not submerged with the sewage, the condition C instanced by Mr. Seudder, viz., "the total bulk of electrolyte employed," has no bearing on the matter.

The condition A, namely, "the area of electrodes immersed," is constant, which therefore leaves only the condition B, viz., the distance between the electrodes, which was the one upon which I based my remarks. It is then stated that "the specific resistance of electrolyte is only a small factor in the calculation required to ascertain the E.M.F. necessary to obtain a given current through a given cell."

In my paper I do not refer in any way to the E.M.F. necessary "to obtain a given current through a given cell," but only to the quantity of current "passed between the electrodes through the intervening sewage."

The resistance offered by the conductors, contacts, and electrodes themselves has nothing to do with the actual amount of current required for the electrolysis of the sewage.

The calculations therefore based upon the resistance of contacts, electrodes, and electrolyte are outside the question, and I still claim that the initial resistance offered by the electrolyte itself in the Salford shoot to the final, if the plates distances were doubled, would be as 5 to 9 as near as working conditions would allow.

The question of pitting does not affect the matter one way or the other. If any advantage were derived from pitting, why not bore through the plates to begin with? Even assuming that uniformly bored plates give an increased surface exposure, iron plates when used as electrodes do not pit to order, uniformly, but generally just in one or two places, and just as easy as it is to suggest 144 holes from pitting in a 1-ft. square plate, so is it to suggest one 9-in. hole in a plate 10 ins. in diameter, in which case nearly all the electrode would be gone.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

The names in italics are those of Members of Committee who retired at the end of the current session.

The following have been elected to fill the vacancies, and will take office in July next:—Chairman: G. T. France; Vice-Chairman: A. Allhusen; Committee: John Pattinson and T. W. Stuart.

### SESSION 1894.

Meeting held in the Durham College of Science,  
Newcastle, on Thursday, May 24th, 1894.

MR. A. ALLHUSEN IN THE CHAIR.

### NOTE ON THE POISONOUS ACTION OF LEAD SALTS.

BY PROF. P. PHILLIPS BEDSON.

In a monograph on Lead Poisoning published in 1891, Dr. Oliver describes a series of experiments which were conducted in my laboratory by Mr. R. D. Best, with the object of studying the action of gastric juice upon white lead, as it would appear that the digestive canal is the channel by which lead finds its way into the system.

The experiments were made by taking a given weight of white lead, placing it in a parchment tube, and adding to it a measured volume of gastric juice or other liquid,\* the action of which it was desired to study. The parchment tube with its contents were suspended in a beaker containing a measured volume of pure distilled water, and this again was immersed in a larger vessel containing water, which was heated for several hours at a temperature of 20°–30° C. At the end of this time the contents of the inner beaker were examined for lead, and the amount of lead, existing in a soluble form, which had diffused through the parchment tube, was determined. The results of these experiments, tabulated below, show gastric juice, both natural and artificial, have an appreciable solvent action on the lead carbonate; and further, that the active constituent is the hydrochloric acid. It will also be seen that when gastric juice is employed in the digestion of proteid matter there is a smaller portion of white lead attacked.

White Lead taken.	Lead Dissolved.	Nature of Liquid.
Grms.	Mgrms.	
1	0.005	Per 10 cc. of gastric juice (natural) diluted with twice its volume of water.
1	0.002	" " "
1	0.002	" " "
1	0.001	Per 10 cc. of artificial gastric juice.
1	8.75	Per 10 cc. 0.3 per cent. solution of HCl and 1 grm. pepsin.
1	6.88	Per 10 cc. 0.3 per cent. solution of HCl and 0.5 grm. pepsin.
1	6.93	Per 10 cc. 0.3 per cent. solution of HCl and 0.25 grm. pepsin.
1	7.4	Per 10 cc. 0.3 per cent. solution of HCl.
1	None	Per 10 cc. of solution containing 1 grm. of pepsin.

\* 25 cc. of liquid was used in all cases.

It is usually stated that lead sulphate is non-poisonous, and possibly upon this belief is based the method of giving white lead workers water containing free sulphuric acid to mitigate the ill effects of white lead. In fact, Dr. Farr, in his report on a process for the manufacture of a new white lead, states that: "If a physician were called upon to attend a case of lead poisoning by carbonate, he would administer sulphuric acid in order to convert it into a sulphate or insoluble form of lead. It is obvious that the white sulphate of lead, therefore, carries with it, so to speak, the antidote to the poison."

Such statements as the above appeared to me to suggest a repetition of experiments, similar to those made with the ordinary white lead, using both precipitated sulphate of lead and the new white lead. At my suggestion, Mr. Elsdon, one of the students in this college, made such a series of experiments, the results of which are given below. The outcome of these experiments is to demonstrate that both these materials are dissolved by water to some extent, and more readily by water containing hydrochloric acid in amounts similar to those found in gastric juice. Further, the new white lead appears more susceptible than the precipitated lead sulphate. Undoubtedly, the proportion of the "new white lead" dissolved by the diluted hydrochloric acid is smaller than is the case with the ordinary white lead, the proportion of solubility being about 1:5. Still, such results necessitate a modification of our views as to the non-poisonous action of lead sulphate, and a more guarded attitude towards such traditional empiricism as that which teaches us that lead sulphate is non-poisonous because of its insolubility. Solubility is a matter of degree, and every student of chemistry knows he can decompose lead sulphate by boiling it with hydrochloric acid; in the light of which fact the results of these experiments are not remarkable, since they show that the change which takes place at a high temperature with such ease and completeness, goes on more slowly and gradually at a lower temperature and with very diluted hydrochloric acid.

New White Lead. Weight Taken.	Weight of Lead Dissolved.	Nature of Solvent.
Grm.

## NITRATE OF SODA IN EGYPT.

BY W. COSSAR MACKENZIE, F.R.S.E., F.C.S.

THAT the natives of Upper Egypt used a natural manure, got from the hills on both sides of the river, has been known for some time to those who have to go there and who take an interest in the doings of the people, but what was the exact nature of the fertilising ingredient does not seem to have been known. Beyond a casual knowledge of the fact that this material was used as a manure, no further interest seems to have been taken in the subject.

In one of his journeys there, Mr. R. A. Floyer obtained several samples of this species of "tail"—"tail" is the name applied to clays used for pottery as well as these manurial clays—and handed them over to me to examine. The samples were pieces selected at random from heaps of the material on land or in boats, and cannot be taken as representative of the whole. As may be seen from the subjoined table, the valuable ingredient is nitrate of soda, and this is present in proportions varying from 2.5 to 18.5 per cent.

Thinking the matter of more than ordinary importance, I determined to take the first opportunity that presented itself of going there to see the deposit and take samples personally, especially as the exact spot from where Mr. Floyer's samples were got was not known. A short vacation at the end of Ramadan—the Mohammedan month for fasting—afforded a suitable opportunity, of which I availed myself. The Nile Valley, above the delta, is generally from 4 to 9 miles wide and is flanked on each side, as far south as Edfon, by ranges of hills of rammed limestone. South of Edfon the rock becomes sandy in character. Between Kench and Esneh, a distance of about 75 miles, these nitrate deposits are found in detached places near the foot of the limestone hills. Luxor, as being about the centre of this stretch and most suitable in every way for the purpose in view, was visited, and an excursion made to the "Gebel el Tail"—clay hill. As guide, a man was got who goes there for the manure, and a start was made about 7 a.m. The journey took, by camel, about three hours, and the distance was probably about 12 miles across the desert. About 4 miles before reaching the "Gebel el Tail" we passed the "Gebel el Gheir"—lime-hill—a very white limestone, with 10 per cent. of sand, but otherwise very pure, and from there, on, the valley was strewn with symmetrical flint nodules. A short distance before reaching the main deposit, a bank of dark coloured material was passed, which the guide stated to be poor tail, and on analysis it was found to contain only 0.28 per cent. of sodium nitrate. The main deposit lay on the sloping face of what appeared to be the highest hill of the district, but to which the guide could give no name but "Gebel"—hill—or "Gebel el tail," and appeared to have a height of 10 or 12 metres; how deep the deposit was, I am unable to say. This deposit did not seem extensive, and lay approximately in the centre of a bay or segment of a circle formed by the limestone rocks, but the guide said there was more "tail" to the south and to the north. The rocks rose perpendicularly for some 10 metres above the "tail" and contained many flint nodules, in some places so numerous as to give the rock the appearance of conglomerate. The strata in Egypt dip gradually from south to north, and this precludes the idea of this being a stratum of nitrate bearing clay cropping out at intervals from north to south. That the nitrate came from the remains of old villages and was absorbed by the clay does not seem possible, looking to the appearance and situation of the deposit. It seems more probable that caves or hollows in the limestone cliffs acted as receptacles for clay and organic matter from the water. After the retirement of the water, nitrification of the organic matter set in, aided by the warmth of the climate and the presence of calcium carbonate, so that the nitrate was formed where it is now found.

## COMPOSITION OF NITRATE-BEARING CLAYS.

*Received from Mr. Floyer.*

	1.	2.	3.	4.	5.	6.
Silica, $\text{SiO}_2$ .....	25.41	25.18	15.83	31.12	37.05	27.68
Silicic acid.....	14.34	27.53	16.37	22.53	21.67	22.81
Carbon dioxide.....	11.77	9.20	8.13	7.92	6.37	5.92
Phosphoric acid, $\text{H}_3\text{PO}_4$ .....	0.57	0.28	1.72	0.29	0.13	0.27
Sulphuric acid, $\text{H}_2\text{SO}_4$ .....	3.82	12.65	9.87	7.13	12.30	6.87
Chlorine.....	4.90	9.20	12.92	6.31	1.18	6.31
*Nitric acid, $\text{N}_2\text{O}_5$ .....	9.40	1.63	9.94	8.82	3.89	11.77
Alumina and iron oxide.....	15.40	2.090	11.25	18.79	18.65	18.26
Lime.....	18.90	9.90	13.31	13.33	11.84	11.51
Magnesia.....	0.67	1.68	1.13	1.12	2.56	0.96
Potash.....	6.40	0.15	3.45	6.18	0.50	0.21
Soda, as hydrochloride.....	19.71	7.00	15.77	12.55	12.49	13.84
Less oxygen equivalent to Cl.....	1.05	2.90	2.69	1.35	0.84	1.35
*Equivalent to sodium nitrate.....	14.89	2.53	15.65	13.89	6.13	18.53
Total soluble matter.....	27.26	36.14	50.58	32.50	29.60	37.04

Samples were taken from the deposit: the loose upper surface was first removed and pieces of the clay were taken from different places and afterwards analysed with the following results:—

## COMPOSITION OF NITRATE CLAYS.

*From Gebel el Taql, Luxor.*

	1.	2.	3.	4.	5.	6.	7.	8.	9.

The first eight samples in the above table were all taken from the main deposit, number nine was from the bank of dark-coloured material, said to be poor tail, already referred to. The first eight samples were taken from different places at different heights, but all from the same deposit; number one was from the bottom, and number eight from the top, while the intermediate numbers were taken from places between one and eight.

As is at once seen, the percentages of nitrate in these samples from the same place vary very much; and this is readily understood. Wherever the rock was cracked crystals of salt were to be seen, indeed all exposed surfaces gave visible indications of salt, but where freshly broken no crystals and no appearance of salt was found though the clay had a distinctly saline taste. One large block had a crystalline coating with crystals half an inch long. On analysis this efflorescence was found to consist

of 65 per cent. of nitrate and 35 per cent. of chloride of sodium. Taking these facts into consideration it is evident that great care must be used, in taking samples, to have the surfaces removed and the rock cut into so that specimens may be obtained which have been affected as little as possible in this way. Since this discovery of nitrate was reported Mr. Floyer and Professor Sickenberger, of the Cairo Medical School, have been sent to Upper Egypt to enquire into the whole subject, and endeavour to form an opinion as to the quantity of material available. The annual consumption of this material in Upper Egypt has been estimated at 500,000 tons, but this is, in my opinion, too high an estimate: half of that quantity will more nearly represent it.

Whether Egyptian nitrate of soda will ever appear as a commercial product in European markets cannot be decided until the results of Floyer and Sickenberger's investigations

are known, but unless richer varieties are found than that got at Luxor the extraction and purification of nitrate for commerce is not very probable.

Means of conveying the tail from the hills to the river are wanting. Egypt is a narrow strip of arable land along the banks of the river, and so the river is the principal "road" of the country, and others are almost unnecessary. Out into the desert there are of course no roads. The railway does not yet extend up there, and when it does it will not pass near the tail deposits, but through the cultivated land. Nothing is left but the means of conveyance at present in use. The construction of a railway or tramway is hardly feasible, seeing that the tail is got in detached deposits, sometimes at considerable distances from each other. At present the tail is transported by camels and donkeys. One journey per diem is all that can be expected from each animal, and taking the load of a camel at 500 lbs., and his cost per diem at 1s., the cost of bringing 10 tons of clay to the river bank amounts to 2*l.* 5s. If the clay contains 10 per cent. of nitrate, 2*l.* 5s. will be the cost of conveying 1 ton of nitrate to the river, for of course the extraction must be done at the river, there being no water in the desert, and is a very large item to be added to the cost of extraction. There seems room, however, for profit, even at that percentage. Should, however, the average percentage be only five, the cost for carriage per ton of nitrate would then be 4*l.* 10s., and would probably render the extraction of nitrate profitably, hopeless.

### AN ABNORMAL MILK.

By R. R. GREIG SMITH, B.Sc., F.C.S.

IN the spring of last year, attention was drawn to the peculiar property of the milk yielded by a cow in the possession of Mr. Scott, Belford, Northumberland. With it a churn was unnecessary, for, by simply stirring the soured cream with a stick, butter was produced. At the invitation of Mr. Scott, the writer called upon him, and was shown the cow, which was what is known as an Irish-bred beast, and about 10 years old. It had calved prematurely on the 16th April 1893, and consequently was not in its usual condition, neither was there a plentiful supply of fodder, for the spring had been very dry and the meadows were parched, yet, from the 1st to the 31st of May it had yielded 1,257 lbs. of milk, and from the 1st to the 16th of June, 567 lbs., in all 1,824 lbs. during 47 days, or a daily average of 39 lbs., equal to nearly four gallons. The soured cream was semi-solid, and led one to expect that butter made from it would contain a large amount of casein. Mrs. Scott's method of butter making consisted in vigorously stirring the soured cream, contained in an earthenware dairy jar, with a clean wooden stick for about a minute and a half, and, when the butter had broken, adding a little cold water and again stirring for half a minute, by which time the butter was ready for washing and working. When made up it had a very pleasant taste, and was similar in every respect to butter made with a churn in the ordinary way. Samples of the milk, cream, and butter were sent to the laboratory of the Durham College of Science and examined.

The cream, from which butter was repeatedly made in the laboratory, using a spatula and a porcelain basin, contained 57.40 per cent. of fat, an amount considerably above the average of that contained in ordinary cream, whether obtained by the slow methods or by the separator, but similar to that found in clotted cream. The cream rose quickly and formed a very compact yellow layer with its lower surface so well defined, that one would almost have

thought it had formed a cake. The analysis of the milk gave the following numbers:

Fat.....	7.50	..
Solids not fat.....	8.70	..
Sugar by difference.....	..	1.70
Protein N x 6.38.....	..	3.50
Ash.....	..	0.67
Specific gravity.....	1.027	..

The only striking figures in the analysis are those giving the percentage of fat, which is considerably above the average, though not uncommon with the milk of individual cows. The relations between the constituents are slightly different from what we find in mixed milks, inasmuch as the fat calculated by Deep Richmond's formula (Analyst, XIV., 121) is 7.76, a difference of 0.26 per cent., and the ratio between the percentages of ash, proteins, and sugar, which Vieth gives as being in the very constant proportion of 2.9:13.5 to this case as 2:10.8, 12.5.

The ash had an alkalinity equal to 2.05 per cent.  $\text{Na}_2\text{O}$ , and the following figures show its composition:—

Iron and calcium oxides.....	0.84
Lime.....	25.54
Magn. salt.....	2.96
Potash.....	15.08
Salts.....	8.12
Phosphoric anhydride.....	33.16
Sulphuric anhydride.....	3.24
Chlorine.....	13.20
Loss.....	0.77
Oxygen = chlorine.....	10.00
	100.00

The published analyses of milk ash agree in having the constituents very similar to those found, with the exception of potash, lime, and phosphoric anhydride; Kirschner in his *Milchwirtschaft* quotes two analyses which have—

Potash.....	25.42	23.54
Lime.....	21.45	22.57
Phosphoric anhydride.....	21.11	27.68

These would indicate that, in this abnormal milk, there may be a deficiency in one or all of the potassium compounds, viz.:—monopotassic phosphate, dipotassic phosphate, potassic citrate, and an excess of one of the lime salts, probably dialcic phosphate, which might be there to the exclusion of much of the trialcic form.

The butter, made in this curious way, was quite normal, and though higher than the average English butters, did not show the amount of casein that one would have expected from the process of manufacture.

Analysis of the butter:—

Fat.....	83.32
Water.....	15.28
Curd, &c.....	1.30
Salt.....	0.10
	100.00

The volatile acids determined by the Reichert-Meisler-Wollny method had a number 28.4.

A milk somewhat similar was produced by a milking shorthorn cow, the property of Mr. Hedley, Overthwarts, Edlingham, who kindly supplied samples of milk, cream, and butter. The cream was made into butter, in the laboratory, as easily as in the Belford sample; the milk had the following composition:—

Fat.....	4.35	..
Solids not fat.....	9.36	..
Sugar by difference.....	..	5.13
Protein N x 6.38.....	..	3.51
Ash.....	..	0.72
Specific gravity.....	1.0324	..

This milk has an analysis entirely different from the Belford one, though they resemble each other in having the fat lower than the calculated amounts for mixed milks, the fat calculated being 1.66, showing a difference of 0.31 per cent. The Vieth ratio is as 2:9.75:14.25.

In examining the Belford milk microscopically, a few large globules were observed which varied up to 0.001 inch in diameter, but the majority were fairly uniform, and close to an average of 0.0004 inch. According to Kirchner, variations are found up to 0.00039 inch—practically the average diameter in the abnormal milk—the mean being 0.00016 inch. McConnell in his *Agricultural Note Book* gives 0.00019 inch as the average of the Jersey and 0.00014 inch as that of the Ayrshire cow. It will be seen then, that the fat globules in this abnormal milk are very large, practically double the diameter, that is eight times the size, of those in the milk of our Jersey breed, which is admitted to have the largest. The mean diameter of the globules in the Edlingham milk was less than the Belford sample, having an average of 0.0003 inch. The surface tension of the suspended fat globules, in both milks, was very low, pressure on the cover glass being sufficient to make them lose their apparently circular shape and run together with great readiness.

In all probability, the size of the fat globules explains the abnormality, which appears to be much more common than is generally supposed, for there are at present in Belford other three cows, unrelated, so far as is known, to that of Mr. Scott, which possess this property. When the abnormal case was made known in Edlingham, the milks of several individual cows were, when tried, found to be similar. Another case occurs at Riding Mill, and it is likely of frequent occurrence in Britain, though apparently unheard of till lately.

only recently seemed to prove positively the presence or the absence of adulterants, and thus were excellent means of establishing the purity of lard, are at the present time of no value whatever.

We know that, besides some adulterants which have never attained any importance from a commercial point of view, cotton-seed oil, cotton-oil, stearine, lard-stearine, oleo-stearine, are chiefly used in compounding lards. All these substances are to-day differently treated and more carefully refined; and, being therefore in a greater state of purity, they do not give reactions formerly thought to be very characteristic.

We may add that Dr. A. Goske (*Chem. Zeit.* 1892, 1560) referred to lard compounded with oleo-stearine, lard-oil, and lard. The mixtures which he thinks might pass as pure lard, showing the correct iodine number and being free from vegetable oils, are the following:—

	I.	II.
	Per Cent.	Per Cent.
Oleo-stearine .....	25	35
Lard .....	15	25
Lard oil .....	20	40

The first mixture would show, according to Goske, 59.75 for iodine number, and the second one 57.27. On account of the high price of lard-oil we thought it more than improbable that such mixtures would be produced commercially. To confirm our opinion we requested some of the leading firms to give us quotations for oleo-stearine, lard, and lard-oil. According to the average prices on February 20th, 1893, the raw materials of 1 lb. of mixture No. I. and II. would cost—

I. 13.1375 cents.

II. 13.125 „

whereas the price for pure lard at the same day was—

13.125 cents.

For practical reasons, therefore, such mixtures will not be found in the market, and the chemist called upon to determine the purity of lard may safely neglect the search for adulterants of this kind. Moreover, the microscopical examination and the crystallisation-point would establish the presence of oleo-stearine.

Again Ad. Jolles and Ed. Wild (*Chem. Zeit.* 1893, 879) detected sunflower-oil in a sample of oleo-margarine. As they found out that cotton-seed oil is about twice as expensive as sunflower-oil, they think that fits for eating purposes could be advantageously adulterated with the latter oil. Sunflower-oil is a clear liquid with slightly yellowish colour, agreeable smell, and sweet taste. If the difference in price is actually as great as Jolles and Wild state, we do not doubt that adulterations of lard with sunflower-oil instead of cotton-seed oil will be observed by the analyst. We have hitherto been unable to procure a sample of sunflower-oil, in the New York market, and could not get any quotations. We intend, however, to buy a larger quantity of the oil, and propose to compound lard with the same. The various mixtures will be subjected to all the tests for lard, &c., and we hope to be able to publish our results at an early date.

On reviewing the different known properties and reactions of lard and its adulterants, we see, as already stated by many authorities, that the specific gravity, the melting point, the saponification equivalent, the determination of volatile, free, and fixed acids, and the determination of the refractive index, are quite useless for the determination of the purity of lard, as mixtures can be prepared which would give approximately the same figures for all these constants as pure lard itself.

Even for a final confirmation of the result, obtained by more decisive reactions, the above-named tests—very rare cases, where more scientific research is intended, excepted—are of no concern for commercial analytical purposes, and, as far as our experience goes, the analyst may safely dispense with them altogether.

Meeting held at University College, Nottingham,  
on Wednesday, May 23rd.

MR. J. M. C. PATON IN THE CHAIR.

### ON COMMERCIAL ANALYSIS OF LARD.

BY H. SCHWEITZER AND E. LINGWITZ.

WITHIN the last few years the art of refining animal and vegetable oils and fats—and in connection with it, the art of compounding lard, i.e., adulterating lard—has made great progress. Some physical and chemical reactions which

Other reactions—as those with nitrate of silver, after Beechi, after Beechi-Holmer; with chloride of gold, after Labiche and Hirschsohn, which were pronounced to be of the utmost importance in the analysis of lard—have since lost their decisive value.

Meike and Wimmer (Zeits. f. ang. Chem. 1891, 518) found different samples of cotton-seed oil and adulterated lard which behaved like pure lard when subjected to those tests, and thus confirmed the observation previously made by E. Dieterich (Chem. Zeit. Rep. 1891, 117).

Warren's chloride of sulphur test (Chem. News, 1888, 113), which Wiley (Bull. U.S. Dep. of Agric., Divis. of Chem.) thought might prove of great value qualitatively and quantitatively, is, according to recent investigations, useless for analytical purposes, as Warren's observations are not quite correct (Chem. Zeit. 1893, 635—636; Muspratt, 4th edition by Stolmann and Kerl, Vol. III, p. 316).

Of all the better-known tests we have thus left the iodine number, the colour reaction with nitric and sulphuric acids, the test with nitrate of silver after Beechi-Milliau, the rise of temperature with sulphuric acid, the microscopical examination, and the crystallisation point.

Of more modern date is the reaction with phospho-molybdic acid and with saturated solution of picric acid in ether (Pharm. Zeit. 1891, 798; Zeits. f. ang. Chem. 1892, 99).

Recently, F. Ganter (Zeits. f. anal. Chem. 32, 305) described a new method for the colour-test with sulphuric acid, and in the Analyst (Analyst, 1893, 23, 221; Chem. Zeit. Rep. 1893, 251) a new way of reacting with nitrate of silver has been recommended.

All these tests have been again and again examined by us, and we have finally arrived at the conclusion that for the determination of the purity of lard the following tests, when taken in a group, are reliable and decisive:—

- (1.) Test with phospho-molybdic acid.
- (2.) Milliau's nitrate of silver test.
- (3.) Iodine number.
- (4.) Rise of temperature with sulphuric acid.
- (5.) Crystallisation point.
- (6.) Microscopical appearance.

**Test with Phospho-molybdic Acid and with Nitrate of Silver, after Milliau.**—Both reactions are used for the detection of cotton-seed oil and cotton-oil stearine. The first one is carried out as follows:—25 drops of the melted lard are dissolved in 5 cc. of chloroform in a test-tube, then 2 cc. of phospho-molybdic acid solution (10 per cent. Merck) are added. The test-tube is thoroughly shaken, and after letting stand for a short time the liquid settles in two layers. The lower layer is colourless and the upper layer assumes a bright green colour when cotton-oil or any other vegetable oil is present. On addition of ammonia to the acid solution the green colour turns blue.

If the lard is absolutely pure the upper layer remains yellow, the original colour of the reagent (phospho-molybdic acid) not being changed. The addition of ammonia makes the liquid colourless.

All the vegetable oils which we have had occasion to subject to this test gave a decided reaction. A sample of cotton-oil, refined by ourselves by means of chemicals *without heating*, which did not give Beechi and Labiche and Hirschsohn's test showed the above reaction perfectly.

According to Welmans, the discoverer of the test, mineral oils do not show the reaction, and among the fats of animal origin only cod-liver oil acts like the vegetable oils. With some practice it is easy to detect the presence of about 10 per cent. of cotton-seed oil in a compounded lard, but an addition of less cotton-seed oil can hardly be traced by this reaction. On such cases there is only one reaction, which, as far as our experience goes, never fails, and this is the Milliau test with nitrate of silver, as described at length in the Journal of the Am. Chem. Soc. (Journ. Am. Chem. Soc. XV., 164; J. Soc. Chem. Ind. 716, 1893). By strictly adhering to the explicit directions of Milliau, the presence of cotton-seed oil down to 1 per cent. is always shown by the mirror-like precipitate of metallic silver, by which the fatty acids of the mixture are blackened.

No other test can be so confidently relied upon and give a such decided a reaction. In doubtful cases the chemist should at all events resort to its execution.

**Iodine Number.**—The iodine number is valuable for the detection of both cotton-seed oil and oleo-stearine. If determined alone it has no meaning whatever, on account of the fact that mixtures can be produced showing the same iodine number as pure lard, and also because the iodine number of adulterated pure samples of lard varies within very wide limits. Wiley (Bulletin, 13, 18) found pure lard with iodine numbers from 57.34—85.03, Anthor and Zinck (Zeits. anal. Chem. 31, p. 534) from 49.2—52.90, and Nentfeld (Archiv. f. Hygiene, 17, p. 152) from 46—61, the latter fixing the maximum figure for the iodine number of pure lard at 61, which is decidedly wrong. But for a final confirmation of the results obtained by the above-named tests, the iodine number is a very satisfactory determination. Although different chemists have of late proposed changes of the original Hubl method for the determination of the amount of iodine absorbed by the fatty acids of the oleine series, we have, after many experiments, decided not to adopt any of those changes. We still carry out the test as described in Wiley's publication and in R. Benedict's book, "Die Analyse der Fette und Wacharten."

We weigh 0.3 gr. of the lard by means of our weighing pipette (Journ. of the Am. Chem. Soc. 15, 190) in a glass-stoppered reagent bottle of about 500 cc. capacity, dissolve it in 10 cc. of chloroform, and add 25 cc. of iodine solution. We manipulate as described in the above publications. Hubl stated (Dingl. Polyt. J. 253, 281) that the reaction is completed after 1½—2 hours, but that it is immaterial whether the final titration is made after 5 or 48 hours.

Frequently we were requested to carry out the examination of fats and oils in very short time, and we were thus forced to find a method permitting the determination of the iodine number in less than five hours. Although Benedikt states that iodine, which acts very slowly on fat at ordinary temperature, acts very irregularly at higher temperature and shows more complicated reactions, we tried to apply heat to the liquid in which the absorption of iodine took place.

We carried out very many experiments, changing the time and the temperature of the reaction. In the following lines we give only those figures from our records which seem to us to be necessary to justify the changes which we adopted for this determination.

Cotton-seed oil, oleo-stearine, absolutely pure lard, and compounded lard were subjected to examination. With every one of these different experiments a blank test with 10 cc. of chloroform and 25 cc. of iodine solution was titrated after having been exposed for the same length of time to the same temperature. The titrations of these blank tests gave always the figures obtained in standardising the original iodine solution directly. From this it appears that, under the conditions described below, heat does not influence the action between chloroform and iodine solution. The following results were obtained:—

Fat.	After 14 Hours at ordinary Temp.	50° C.			
		5 Min.	10 Min.	15 Min.	20 Min.
Cotton-seed oil.....	108.4	107.2	107.6	107.7	108.8
Oleo-stearine.....	28.0	27.8	26.4	27.0	28.4
Pure lard.....	67.3	67.2	67.1	66.5	67.7
Compounded lard (Roche's Brand)	50.9	58.0	50.0	50.7	50.6

This series of experiments prove that 20 minutes at 50° C. give figures for the iodine number, which are a trifle too high. We therefore repeated the determinations at 40° C. with the same regular result, but found that 20 minutes gave somewhat too low figures. Finally, we resorted to heating at 45° C. and obtained the most constant and satis-

Meeting held Saturday, June 9th, 1894.

PROFESSOR A. SMITHIES IN THE CHAIR.

## CONTRIBUTIONS TO THE ANALYSIS OF FATS. IV.—COLOUR REACTIONS.

BY DR. J. LASKOWITZ.

BEFORE the "quantitative reactions" had opened out a new field of research in the commercial analysis of fats and introduced scientific accuracy into this branch of technical analysis, the qualitative tests or colour reactions were chiefly relied upon, in conjunction with some physical constants and some organoleptic methods, to give such information as the chemist was required to furnish. It must be added that these colour reactions were resorted to only for want of better methods, as is still the case in other domains of technical analysis into which the light of chemistry has not fallen yet or not been allowed to fall.

Writers of older text-books were in the habit of giving tables and systematic schemes by means of which the individual fats, and especially the oils, were said to be classified and identified. Unfortunately, tables of this kind have been perpetuated in even more recent treatises, and the bewilderment of the analyst who tries to find his way through this almost inextricable maze of colour reactions is more easily imagined than described. Nor must it be forgotten that those colour reactions were not always obtained with typical samples, representing what they professed to be, little or no regard having been taken of their source, their age, their mode of purification, and all that host of circumstances that have a vital influence on the colour the reagents produce. With the progress of technical knowledge the purification of oils has simultaneously gone apace, and a number of impurities, the very substances that gave origin to the colours supposed to be characteristic, have ceased to occur in commercial samples.

No wonder therefore that most of that class of tests have been abandoned, and that even some writers have gone so far as to banish altogether colour reactions—with very few exceptions—from the examination of fats and oils.

A given colour reaction can only be of value if it be produced by a well-defined substance, naturally occurring in the oil or fat, and characteristic of it to such an extent that it may be easily identified by that reaction. Of course these characteristic substances, occurring only in minute quantities, must not be easily removable by the processes of refining usually applied in practice.

As a type of a most valuable reaction of this kind may be considered Baudouin's test for *sesamé oil*, which has recently obtained its scientific explanation and confirmation by the isolation of the colour-producing principle in that oil. The colour reaction for cholesterol, although highly characteristic, requires more circumspection, as other substances also give the same or a very similar coloration (this Journal, 1892, 144).

I do not purpose reviewing here all the colour reactions that have been recommended for the identification of individual oils—such as Beechi's test for cotton-seed oil—as I hope to treat this subject shortly in another place. It is rather my intention to deal here with—and to dispose of—some reactions that are still looked upon as allowing a classification of oils and fats.

The following four reagents, sulphuric acid, chlorine gas, phosphoric acid, and phosphomolybdic acid, will be considered here, other group-reagents, as caustic alkalis, nitric acid, &c., being absolutely valueless for purposes of classification.

### A.—Sulphuric Acid.

Small quantities of impurities, such as resinoid and albuminoid substances being apt to produce colorations with sulphuric acid, the sulphuric acid colour test is of but limited value.

At best it is possible, with a good deal of practice, to discriminate between drying oils, semi-drying, and non-drying oils, if the acid be applied to the oil direct. The

first-named oils may be recognised by their forming dark clots when, say, two drops of acid are stirred into 20 drops of oil. A discrimination between semi-drying and non-drying oils, however, is more difficult, and in fact scarcely possible in every case.

The better drying an oil is the darker it will be coloured by the acid, so that it may be possible, judging from the depth of the colour, to distinguish between oils standing at the extreme ends of these classes, such as cotton-seed oil and olive oil, whereas it is impossible to differentiate by this test alone, e.g., rape oil from cotton-seed oil. The colour reactions obtained with a solution of the oil in carbon bisulphide cannot be said to yield more reliable results, the dilution tending to obliterate the otherwise sharp distinction between the eminently drying and the other oils.

In the case of the liver oils, the blue and purple colorations, due to the presence of cholesterol and colouring principles—lipochromes—are very characteristic; they are best observed if the oil be dissolved in carbon bisulphide previous to being treated with acid. But it should be pointed out that upon rancidity setting in, the chromatic principles undergo a change preventing the appearance of the blue colour, purple and red colorations being produced instead. Thus, rancid cod-liver oils, such as "cod oil" and "coast cod oil," not always show the fine blue colour a pure medicinal cod-liver oil will give. On the other hand, blubber oils will also give occasionally the blue colour, e.g., seal oil, so that it would not be safe to assume in such cases a—perhaps accidental—admixture with liver oil.

The sulphuric acid colour test may therefore only be used for purposes of preliminary information, and even then its indications should be interpreted with the greatest caution. It will be found far better to substitute for it the iodine absorption method, which, although entailing more work, furnishes an infallible means for classifying oils and fats.

### B.—Chlorine Gas.

Chlorine gas has been proposed by Fauré (1839) as a general reagent for the distinction of vegetable oils from animal oils, the latter oils—with the exception of the foot oils from terrestrial animals—being said to become black on treatment with this reagent, whereas the vegetable oils are hardly changed. Seal oil was later on added to the exceptions, but still chlorine gas has been generally retained as a reagent characteristic of the fish, liver, and blubber oils (the liquid waxes, sperm oil, and bottle-nose or Arctic sperm oil, being included in the last group).

Being in possession of a large number of oils and fats of undoubted genuineness (many of them had been prepared in the laboratory, especially the oils and fats from terrestrial animals, whereas the others were obtained from absolutely reliable sources as genuine), I have treated most of them with chlorine gas under exactly the same conditions. The following table contains the results:—

### OILS AND FATS TREATED WITH CHLORINE GAS.

#### A.—Vegetable Oils.

No.	Class of Oil.	Kind of Oil.	Colour after Treatment.
1	Drying oils.	Linseed, No. 1	Green
2		" No. 2	Slightly darkened
3		" No. 3	Slightly darker than No. 2.
4		Poppy seed	Unchanged
5	Semi-drying oils.	Cotton "	Slightly darkened
6		Cotton seed heated to 200° C.	Turned dark
7		Sesame, No. 1	Unchanged
8		" No. 2	"
9		Brazil nut	Slightly darkened
10		Rape oil, "cola"	Unchanged
11		" "	"
12		" "	Darkened

## A.—Vegetable Oils—cont.

No.	Class of Oil.	Kind of Oil.	Colour after Treatment.
13	Semi-drying oils.	Mustard seed	Darkened quickly, becoming dark brown.
14		Cotton	Turned dark, then greenish.
15		Castor, No. 1	Turned slightly brown
16		" No. 2	Unchanged
17		Peach	"
18	Non-drying oils.	Almond, bitter	Darkened very slightly
19		" sweet	Darkened less than No. 18.
20		Arachis	Unchanged
21		Olive, Tuscan	"
22		" Galipol.	"
23	Vegetable fat	Laural	Darkened

## B.—Animal Oils.

No.	Class of Oil.	Kind of Oil.	Colour after Treatment.
24	Fish oils	Japan fish	Turned light red, then dark reddish brown.
25		Cod liver, medicinal	Turned light brown.
26	Liver oils	" " rancid	Black.
27		Cod	"
28		Cod, East Coast	"
29		" rancid	Very deep brown.
30		" Norwegian	Almost black.
31	Blubber oils	Seal	Light brown.
32		Seal, Newfoundland "straw,"	Darkened, becoming very deep brown.
33		Right whale, pale	Turned brown.
34		" " dark	Nearly black.
35	Blubber oils, liquid waxes	Sperm No. 1	Very slightly brown.
36		" " 2	Light brown.
37		Bottle-nose (Arctic sperm), No. 1.	Very slightly brown.

38	Blubber oils, liquid waxes.	Bottle-nose (Arctic sperm), No. 2.	Light brown.
39		Bottle-nose (Arctic sperm), No. 3.	"
40		Horses foot	Almost black.
41	Terrestrial animal oils	Neats "	Unchanged.
42		Sheeps "	"
43		Tallow oil	Darkened slightly.
44	Animal fat	Lard "	Darkened very slightly.
45		Horse fat	Became lighter.

From an inspection of this table the conclusion becomes evident that the chlorine cannot be admitted as a reagent for marine animal oils, the black colour being conditioned by the state of purity, No. 9—13, the treatment, No. 6, and especially the state of rancidity, and not by the origin of the oil. In fact, the pure cod-liver oil (25), and seal oil (31), changed their original colour so slightly when compared with No. 6, 9, 13, that they might be placed—judged by the chlorine test alone—amongst vegetable oils. On the other hand, horses foot oil, No. 40 (rendered some years ago by myself), became almost black.

The chlorine test must therefore be struck out of the list of special reagents for marine animal oils.

## C.—Phosphoric Acid.

In the table given by Grace Calvert (1854) syrupy phosphoric acid appears as a useful reagent for marine animal oils. Schaedler recommends it most strongly for this purpose, substantiating its claim by the assertion that even 0.1 per cent. of a marine animal oil may be detected by means of the red coloration phosphoric acid produces. Holde (this Journal, 1890, 419) has already stated that the phosphoric acid test is uncertain, as on the one hand resin oils also produce the red colour with this acid, and on the other hand distinct colorations only appear when large quantities of blubber oils are present in other oils. The following table proves that no reliance must be placed on this reaction, as the acid seems only to indicate impurities in oils, that can be eliminated by refining (No. 26), or products of oxidation (No. 7) or rancidity (No. 16).

## OILS TREATED WITH SYRUPY PHOSPHORIC ACID.

1 Volume of Oil with 5 Volumes of Acid.

31		Lard oil	" " "	Dirty yellow.

## C.—Phospho-Molybdic Acid.

Welmans (this Journal, 1892, 548) has proposed this reagent for the detection of seed-oils in lard, and generally for the discrimination of vegetable oils from oils and fats of animal origin, with the exception of cod-liver oil. Guided by the consideration that the fixed oils as products of the vegetable organism may contain minute traces of alkaloids or glycosides, he applied to a number of vegetable oils the reagents used for the detection of alkaloids, with the result that phospho-molybdic acid was found suitable.

The reaction is carried out as follows:—1 gram. (or 25 drops) of an oil or fat is dissolved in 5 cc. of chloroform in a test-tube and agitated with 2 cc. of a freshly-prepared solution of phospho-molybdic acid, or of sodium phospho-molybdate and a few drops of nitric acid. After standing for a short time, the chloroformic layer becomes colourless, whereas the upper layer shows, in the case of a vegetable oil and cod-liver oil, a green colour. On adding ammonia or a fixed alkali a beautiful blue colour appears, the intensity

of which corresponds to that of the green tint noticed before. Animal fats, such as tallow, goose fat, butter fat, and lard do not give this reaction, according to Welmans, nor is a green colour said to be obtained with vegetable oils refined by means of acids, as rape oil, or only after very long standing (compare, however, rape oil, in the following table). This reaction has been recommended by several chemists—Engler and Rupp, Wimmer, Mansteld, Goske—with the only limitation by Wallenstein (this Journal, 1893, 55), that also tallow ("premier jus") gives a green resp. blue coloration.

The importance of a reaction of this kind naturally attracted my attention, and I made an extensive trial of it with the result tabulated below. The extreme sensitiveness of the phospho-molybdic acid to minute traces of reducing substances such as impurities in commercial ammonia (organic bases) required a preliminary examination of the ammonia and the chloroform used. Both left the phospho-molybdic acid yellow, and the latter became colourless on supersaturation with ammonia.

## OILS AND FATS TREATED WITH PHOSPHO-MOLYBDIC ACID.

62		Lard, freshly rendered, filtered.	(a.) (b.) (c.) Yellow .....	" "
63		Lard, six years old, slightly rancid.	(a.) Yellow, (b.) Yellow.....	(a.) Very faint blue, (b.) Faint blue.

A glance at the tables proves clearly that, even excepting the liver oils, a distinction between vegetable and animal oils and fats cannot be made by means of the phospho-molybdic acid. Several kinds of olive oil as also almond oil, arachis oil, and peach oil, showed far less distinct reactions than tallow oleine and even lard oil. The reduction of the phospho-molybdic acid is evidently caused by minute quantities of impurities in the oils and fats themselves or by some secondary products appearing with even slight rancidity setting in. This is most notably proved by the reaction obtained in the case of No. 63.

Of all the samples tested, only lard had remained colourless, and there seemed to be ground for the opinion that cotton-seed oil or any other seed oil employed for adulterating lard might be easily detected by phospho-molybdic acid. I prepared therefore a number of mixtures of pure, freshly-rendered lard, yielding no coloration in Welmann's test and of cotton-seed oil giving a distinct blue reaction. The results are given in the subjoined table.

## MIXTURES OF LARD AND COTTON-SEED OIL TESTED WITH PHOSPHO-MOLYBDIC ACID.

No. 1.	Lard.	Cotton-seed Oil.	Colour of the Acid Layer.	Colour when made Alkaline with $\text{NH}_3$ .
	Per Cent.	Per Cent.		
1	100	..	Yellow	Colourless.
2	95	5	"	"
3	90	10	"	Almost colourless.
4	85	15	"	Very faint blue, like No. 63 of preceding table.
5	80	20	"	Faint blue.
6	75	25	"	"
7	70	30	"	"
8	65	35	Slightly greenish	"
9	60	40	"	Bluish.
10	50	50	Greenish	"
11	45	55	"	"
12	40	60	"	"
13	35	65	"	"
14	30	70	Slight green	"
15	25	75	"	"
16	20	80	"	"
17	15	85	Green	Blue.
18	10	90	"	"
19	5	95	"	"
20	0	100	"	"

There was a gradual increase in depth of tint, which, of course, could not be expressed in the table as distinctly as would be necessary to mark the slight increments.

This table clearly demonstrates the necessity of using Welmann's test with great caution. In practical analysis, an adulteration with 10 per cent. of cotton-seed oil would escape detection if freshly-rendered lard had been used. Indeed, pure lard mixed with 15 per cent. of cotton-seed oil gave a reaction just like sample No. 63 in the preceding table. If in the examination of that sample of lard preponderant importance had been given to the results of Welmann's test, an adulteration with from 15 to 20 per cent. of cotton-seed oil would have been pronounced upon. As all other physical and chemical constants would have pointed to a normal lard, the analyst would have naturally proceeded to look for the compensating beef stearine, and he would perhaps—under the strong bias—succeeded in finding it, and thus might have added another page to the already too voluminous chapter of adulterations, winding up with a panegyric on the ingenuity of the adulterator, who is credited with being several years ahead of the analytical chemist.

The fact that rancid lard has a reducing action on phospho-molybdic acid is a welcome corroboration of Bevan's (Analyst, 1894, 88) recently published statement that lard which had been exposed to air gave a strong reaction with silver nitrate. Both reactions show that products of an aldehydic nature are formed when the fat turns rancid.

Welmann's reaction can therefore be only admitted as a preliminary test, the indications of which may in some cases give valuable hints as to the directions in which the examination of a given sample has to be carried out, or may serve as a useful corroboration of results obtained by other methods. This becomes all the more evident if we examine the following table, containing some unsaponifiable substances often met with in the examination of fats and oils.

## BEHAVIOUR OF UNSAPONIFIABLE SUBSTANCES WITH PHOSPHO-MOLYBDIC ACID.

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*The Prevention of Scale in Boilers.* J. Walter. Chem. Ind. 16, 487.

If the water is fed into the boiler, together with small quantities of a solution of sodium carbonate, the deposit of scale is not prevented, but is localised more upon those parts which are nearest to the opening of the feed-water pipe in the boiler. The probable cause of this is the difference between the temperature of the water in the boiler and that of the feed-water. If therefore the temperature of the feed-water were raised to the temperature of the boiler before coming in contact with the latter, all incrusting matters would be precipitated beforehand and no scale could form upon the boiler plates. To effect this result a 6-in. tube is placed on low supports along the centre of the boiler at a distance of about 6 in. from the bottom. The front end of this tube is open, the back end closed with a blank flange. From the back end rises a vertical pipe reaching above the level of the water in the boiler and loosely encasing the feed-water pipe. The water fed into the boiler does not therefore mix immediately with the water in the boiler, but passes first through the narrow vertical tube and subsequently through the wider horizontal tube. During this passage its temperature rises to that of the boiler, and the incrusting matter is precipitated within the horizontal tube, no subsequent formation of scale upon the boiler plates taking place. Any of this precipitate washed out of the tube, will be found to form only a layer of fine sludge on the bottom of the boiler or a granular coating on the sides, which is easily removed by a brush. The greater part of the precipitated incrusting matter will be found in the horizontal pipe, which after being cleaned is reinserted. This arrangement was found to form a reliable means of preventing the formation of hard scale.—C. O. W.

## PATENTS.

*Improvements in and relating to Apparatus for Heating or Evaporating Liquids by Means of Steam.* D. B. Morrison, Hartlepool. Eng. Pat. 9548, May 12, 1893.

This invention relates to heaters composed of tubular coils inserted in evaporating vessels, and consists in arranging the coils in such a way as to facilitate their withdrawal from the vessel for cleaning or other purposes without necessitating the breaking of any pipe joints. For this purpose the coils are connected to the pipes both for the admission of the steam and for the removal of the condensed water, by means of hollow taper plugs on which they can be moved as on hinges, and can be swung clear from the inside to the outside of the vessel whenever required. The figures accompanying the specification illustrate a variety of arrangements based on the same principle.—B.

*Apparatus for Extracting Substances by Volatile Solvents.* J. Meikle, Glasgow. Eng. Pat. 10,701, May 31, 1893.

A closed vessel, divided into upper and lower compartments by a horizontal perforated partition, is suitably jacketed at its ends and sides, and the two compartments are provided with heaters and stirrers. The substance to be treated is charged into the upper compartment, and the solvent is sprayed over it by means of a perforated ring pipe, while the substance may be stirred and heated as desired. The solvent passes through the perforated diaphragm, and falls to the bottom of the vessel, where it may be vaporised by the heater and caused to pass by a central vertical pipe to the upper chamber, where it condenses on meeting with the upper cover, through which latter a current of cold water is passing. The liquid, thus condensed, gravitates through the substance and collects below, where it is vaporised again; a continual circulation is thus kept up. The extracted substance, with the solvent, is finally drained off from below and the vessel is cleared for a fresh charge of substance.—E. G. C.

*Improvements in Apparatus for Cooling, Heating, Drying, or similar Purposes.* J. Fischer, Vienna. Eng. Pat. 10,870, June 5, 1893.

This invention applies to apparatus in which the heating or cooling unit is the flat hollow plate, through which the heating or cooling medium circulates, and the improvements refer to the method of constructing the plates, and of connecting the various units together in a way to secure due circulation from one to the other and the regular withdrawal of the condensed liquor. In some cases the induction of counter-currents in the liquids or gases requiring to be heated or cooled is also provided for.—B.

*Improvements in Evaporating Brine and other Liquors, and Apparatus therefor.* F. W. Scott and F. W. Scott, jun., London, and E. G. Scott, Liverpool. Eng. Pat. 12,774, June 29, 1893.

In the apparatus hitherto used for the evaporation of brine or other liquids *in vacuo* the heating system has been generally situated within the evaporating vessel, whereby crystals or other deposits frequently covered the heating surfaces and so impaired their efficiency. The object of this invention is to overcome that difficulty by heating the liquid in a separate vessel, before allowing it to enter the evaporating vessel, in which the crystals are subsequently thrown down under the influence of the vacuum. The accompanying figure illustrates the principle.

Here *b* is the heating vessel traversed by the tubes *c*, fed with the liquid through the inlet tube *d*. It is surrounded by the tube *e*, closed at its upper end by the valve *j*, weighted to any desired degree by the spring *k*. The heating steam enters the vessel *b* by the tube *g*, and the heated liquid escapes under pressure by the tube *f* to the evaporating vessel *a*, wherein the crystals are deposited under the action of the vacuum, and are removed through

\* Any of these specifications may be obtained by post by remitting sd.—the price now fixed for all specifications, postage included—to Sir Henry Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

the valve *m*, which is constructed as described in a previous patent, Eng. Pat. 6478 of 1892 (this Journal, 1893, 347). Any remaining liquid is drawn off through the pipe *l*, and

the water of condensation from the vessel *b* finds its way through the tube *h* into the hot-water jacket surrounding the vacuum vessel, and can be withdrawn at *i*. The system can also be applied to multiple effect apparatus.—B.

*Improvements in the Construction of Blast Furnaces, Shafts, or Chimneys, or like Structures, and in Bricks or Blocks to be employed therein.* W. P. Ingham, Middlesbrough-on-Tees. Eng. Pat. 12,910, July 1, 1893.

IN the construction of blast furnaces and other structures built of bricks or blocks it has hitherto been usual to form the blocks in plan of a tapered shape, the sides of each block being formed in continuation of radial lines drawn from the centre or axis of the structure, but this method of construction does not form a structure that will resist much internal pressure.

The patent relates to the use of bricks of such shape that the joints between them are not radii of the circular cross section of a structure of the class of a chimney or blast furnace, but are tangential to a circle of moderate radius concentric with the circle constituting the cross section. Drawings are given of bricks which fulfil this condition. Greater stability of structure is thus attained.

—B. P.

*Improvements in Apparatus for Crushing Dry or Wet Materials, such as Cement, Lime, Powder, Anthracite, Kainite, Quartz, Phosphate Minerals, and the like.* C. Moré, La Roche, France; J. A. Hempel, Dronne, France. Eng. Pat. 13,771, January 22, 1894.

THE crushing mill consists of a heavy annulus weighing several tons provided with a recess or groove on its inner surface for the reception of the material to be crushed. The ring is supported by two rollers running in the track formed by the inner groove, and one of these rollers is rotated by any suitable means to cause the annulus to revolve. The material is fed into the hopper of the machine by an Archimedean screw arrangement, or any equivalent device, from whence it is delivered into the annular groove and is distributed evenly by means of spherical rollers. The material passes over the rollers, where it is crushed, and afterwards meets an adjustable angled scraper, which delivers it into a sieve or other receptacle. E. G. C.

*Apparatus for Distilling and Sterilising Water.* J. Nagel, Chemnitz, Saxony. Eng. Pat. 25,888, February 6, 1894.

THIS apparatus (see next page), which is designed for the simultaneous distillation and sterilisation of water, is constructed as follows:—

The water to be treated enters the closed vessel *F* by the pipe *Y*, rising by the pipe *Z* into the space *d* under the condensing vessel *G*, thence by the pipe *f* and through the regulating valve *g* into the body of the said vessel *G*, where, after filling the space surrounding the vertical tubes *N*, it finds an outlet near the upper end through the bent tube *H*. On descending the latter tube (the cock *r* being closed) the water reaches the system of heating tubes *R* and *E* over the firegrate, and the evaporating vessel *D*, which it fills to a height indicated by the gauge glass *K*. The vessel *D* is surmounted by the steam-tube *F*, closed at its upper end by the weighted and balanced valve *m*, which passes through the perforated plate *e*, and is in connection with the regulating valve *g* through a lever and the rod *h*. On steam being raised to the desired pressure in the vessel *D* it escapes through the valve *m* into the dome-shaped space above, and, passing through the tubes *N*, is condensed. The resulting water drops into the conical space *c*, thence passing through the tube *Q* and the cooled coil *S* finally issues, as distilled water, by the pipe *X*. The small bent tube *V* acts as a safety-valve against undue steam pressure, whilst the siphon-pipe *L*, which can be provided with the thermometer shown, enables a portion of the heated water to flow off direct from the vessel *D* after having been sterilised by boiling. The automatic feeding of the apparatus is regulated by the action of the valve *m*, which, on rising through increased steam pressure, simultaneously opens the feed-valve *g*, thereby admitting fresh water, which in its turn has a cooling effect upon the contents of the vessel *D*, tending to reduce the steam pressure and to close the steam-valve. The tap *r* is provided for the purpose of emptying the apparatus.—B.

*Improvements in Apparatus for Separating, Classifying, and Purifying Minerals and other Materials.* A. F. Beyer and A. G. Beyer, Paris. Eng. Pat. 3478, February 20, 1894.

THE object of the invention is the simultaneous pulverisation and classification according to density, of minerals and other materials, and in particular, natural phosphates of lime, the classification being effected through the continuous agitation of the raw materials with air or other gas simultaneously introduced into the apparatus during pulverisation. A simple separating apparatus as constructed under this patent is composed of:—1st. A compressed air pulverising beater running at great speed. 2nd. A sloping delivery tube for the pulverised products, the axis of the mouth of the tube being set at an angle to a vertical plane passing through the axis of the beater. 3rd. A classifying chamber with centrifugal action placed at the far end of the delivery tube. 4th. An auxiliary fan placed upon the axis of the beater for introducing a current of air in the path of the

material leaving the sorting apparatus. Modifications are included both in the treatment and in the apparatus, as well as in the construction and arrangement of details.—B.

*Improvements in Apparatus for Creating a Vacuum in Vacuum Pans.* P. Pié, Lima, in the Republic of Peru. Eng. Pat. 4906, March 8, 1894.

A CENTRIFUGAL pump has branch pipes connected to the vacuum pan and to a cold-water supply, so that when the pump is set in motion, the steam from the vacuum pan is

drawn into the inlet pipe by the action of the pump, where it meets with the cold water. The vapours immediately condense by contact with the cold water and are discharged through the outlet pipe. The cold water is finely divided by a rose, and can be regulated by a cock so as to produce the required vacuum.—E. G. C.

## II.—FUEL, GAS, AND LIGHT.

*Liquid Fuel.* G. Stockfleth. See Arts. 42, 616—625.

In introducing the author—formerly engineering expert of the Nobel Petroleum Production Company.—Mr. Boverton Redwood animadverted upon the trifling progress made in the practice of liquid fuel burning in this country, since Dr. B. H. Paul's paper before the Society in 1868, although he himself, in 1886, had been able to describe its then already very extended use in Russia, this use being largely due to the efforts of Mr. Uspubart, the locomotive superintendent of the Grazi-Tsaritzin Railway.

After some remarks upon the oils suitable for liquid fuel and upon the distillation of petroleum, Mr. Stockfleth stated that in 1892 the production of Russian *astatki* (residue remaining in the petroleum stills at 300—320° C.) was about 3,350,000 tons, of which 3,000,000 tons were exported to Caspian ports, and 250,000 tons to Batoum, while 100,000 tons were consumed in Baku.

*Astatki* is even used for domestic cooking and heating by leading it from a tank, at the top of the house, to the various stoves, where it drips on to a small cast-iron plate placed in front of the stove door, which is provided with a small opening, creating a strong draught; when once the plate is warm and the dripping of the oil properly regulated, it burns without further attention.

For the larger uses (steam-raising, distilling, &c.) many "*fasunkas*" (atomisers or injectors) have been invented; but "it has been found that the most primitively constructed pulverisators answer as well as the more complicated kinds." That atomiser which at present is giving "entire satisfaction" under the still, neither wasting drops of oil nor giving smoke nor chimney-flame, is made by simply flattening under the hammer the ends of two  $\frac{1}{2}$  in. pipes, so that the apertures are about  $\frac{1}{4}$  in.  $\times$   $\frac{1}{8}$  in. or  $\frac{1}{16}$  in., and binding them together with a piece of wire; steam is then led through the one, its jet catching and completely spraying the slightly warmed *astatki*, which descends by gravitation in the other.

According to the author, the action of the steam is "solely mechanical and serves only for cutting up the oil in small particles, which, being surrounded by the necessary air for their combustion, catch fire before they reach the bottom of the flue." Compressed air has been tried for spraying *astatki*, "but the results have not materially differed from those obtained with steam." The author points out that any chemical action which the steam might have upon the oil would probably already have taken place in the stills, where steam is used to facilitate distillation; the question of the possible dissociation of the steam, at or near the moment of combustion of the *astatki*, was not discussed in the paper.

The amount of steam, consumed in atomising the *astatki*, is stated to be "usually estimated at from 5 to 7 per cent." in Russia; but (in the discussion of the paper) Mr. E. Charrington gave 2½ per cent., as the result of his experience with stationary boilers; Mr. Nelson Boyd stated that, in the recent voyage of the "*Baku Standard*" across the Atlantic, each ton of liquid fuel had consumed a ton of water as atomising-steam, a result which, Mr. E. Henwood and Mr. W. Warren explained, was probably due to the wasteful and imperfect apparatus employed on the ship; whilst Mr. Boverton Redwood, in alluding to the importance of this part of the subject, stated that some burners used much more than others, and that, in comparative critical trials, many of the modern burners would probably be found to yield more economical results than the somewhat primitive Russian apparatus described by the author.

The advantages of liquid fuel are:—ready adaptability to existing furnace arrangements; greater steam-raising power; complete and ready control over the fire, and absence of smoke and ash. Steam can, by this means, be very rapidly raised and the fire can be instantly lighted or extinguished; there is little waste and noise of steam by the safety-valve, and the boiler-pressure can more readily be regulated. The furnace doors need seldom be opened, heat being thereby saved and leaky boiler-tubes less frequently caused by cold air currents. Great saving (about

two-thirds) of the space at present devoted to storage would be effected, for only half the tonnage of stock need be stored, and this amount would occupy a less space than the same quantity of coal. Almost all the labour employed in storing, loading, and handling coal, as also that of feeding and stoking the fires, is directly saved.

As to ships, the valuable space, given up at present to coal bunkers, becomes available for cargo, the oil being stored in ballast tanks at the bottom of the ship; the stability of the ship is thereby augmented, and the oil, as consumed, is replaced in the tanks by water. One-quarter the number of stokers are required, and the size of the stoke-hole may be greatly reduced; the danger of fire in the coal-bunkers will no longer exist, and there is less risk of accidents from scalding when water, during stormy weather, puts the fires out. Liquid fuel is especially suitable for torpedo boats.

As yet there is no boiler specially designed for liquid fuel in the market but the author considers the recent water-tube type much more suited to the fierce fire of liquid fuel than are older types, with straight or curved surfaces of ordinary thick boiler-plate.

As to the cost of liquid fuel, the author did not consider it "at present very probable that this fuel will be adopted to any considerable extent in this coal-producing country, with its annual output of 185,000,000 tons," but that in other parts where oil is found on the spot and coal is expensive, very good markets could certainly be created.

In the discussion, Mr. Nelson Boyd did not think any kind of liquid fuel could be delivered, in the Thames under 2½d. per gallon; but calculating 2d. per gallon (16s. 8d. per ton) and allowing the efficiency of petroleum to be twice that of coal, this would compare with coal at 23s. per ton. Now, except in a time of coal famine, the best steam coals only cost (at Cardiff) 12s. to 13s., while a very good coal could be bought for considerably less. In steam-raising, Mr. Henwood had obtained an "evaporation" considerably over 3 to 1 as compared with coal, and he contended that English shale could yield petroleum at under 2d. per ton. Mr. Charrington found, in practice, *astatki* compared, as to efficiency, with coal in the ratio 2:1:1. *Astatki* was 25 per cent. dearer than green oil, creosote oil, and tar residuals; a ton of mixed green oil and creosote oil at 2d. per gallon was equal to 1 ton of coal at 16s. 6d. There were 25 oil-consuming locomotives on the Great Eastern Railway, and, during the coal strike, even petroleum had been found to pay; ordinarily, oils from various gasworks along the line were used; these oils cost ½d. per gallon delivered into tank trucks on the line. This use of liquid fuel was thus one existing under quite exceptional circumstances. Upon the questions of the present and future sources of the supply of liquid fuel, the author stated that it was improbable that any great supply could be expected from the American oil-fields; for only 20 per cent. of residuals, higher in density than kerosene, is yielded and part of this is used in preparing other petroleum products; the 65 per cent. of *astatki*, yielded by Russian petroleum, gives a considerable quantity available from these fields. As to whether other regions will ever yield such enormous quantities, as do these two, "all that can be said is, that several places in different parts of the world present quite as good indications of the presence of oil, as the others did before they were worked."

Among such promising countries are specially to be noted Java and Peru, which produce heavy petroleum, as also Burmah, Trinidad, and several of the West Indian islands, Canada, Mexico (both on the Pacific and the Gulf sides), Galicia, Sumatra, and Japan are also highly petroliferous countries.

During the discussion Mr. Henwood said, that although there was an immense amount of petroleum in Trinidad, the impost of 8s. per ton retarded its development. Venezuela also was highly petroliferous. Mr. Warren stated that the entire United States production for 1893 was 37,000,000 barrels, which would only produce 1,500,000 tons of *astatki* and light naphtha, and seeing that the Pennsylvania Railway used 5,000 tons of soft coal per diem, this company alone could consume the entire petroleum liquid fuel output of the States. The coal output of England for 1892 was

183,000,000 tons, and that of the United States 181,000,000 tons, or together nearly 400,000,000 tons, whilst the entire petroleum output of Russia and the States was together only 10,000,000 tons; it was therefore unlikely that the supply of oil would ever exceed the demand. Sir Westley Pervail mentioned the extensive petroleum deposits of New Zealand.

In some concluding remarks upon drilling for oil the author stated that, in the United States, a complete outfit costs 10,000 dollars, and drillers' wages average from three to four dollars per diem—if for work outside the States, 125 dollars per month and travelling expenses. In Russia the total cost of a well is about 3,000l. under contract. Before putting down such expensive wells, it is recommended to test a supposed petroliferous property by means of 4-in. holes carried down 500 ft., the necessary plant and casing for such work costing 350l. to 475l. Wells in Russia have a top diameter of 20–24 in. and a depth of about 800 ft., while in America the corresponding dimensions are 8 in. and 2,500 ft.

Mr. Byverton Redwood summed up the liquid-fuel question in the following sentences:—"Unfortunately, up to now, users and producers have waited for each other, and it seems that there ought to be a little more courage, on the part of those who have valuable sources of supply, in developing them. There is too much disposition to wait until they are assured of a demand for so many thousand tons per annum; while, on the other hand, those who might be inclined to use this material say they cannot be expected to make arrangements to use it until they are assured of a constant supply at a certain price. The result is almost entire stagnation."—E. R. B.

*Spontaneous Combustion of a Lamp Shade.* A. Dupré. Times, May 23, 1894.

See under Analyt. and Scient. Notes, page 670.

## PATENTS.

*Improvements in the Manufacture of Coke, Coal-gas, and the Obtaining of By-products, and in Apparatus employed therein.* P. Dvorkovitz, London. Eng. Pat. 5546, March 14, 1893.

According to this invention the oven, retort, or chamber is constructed so that heat can be applied to the interior of the mass of coal as well as to the walls of the chamber containing it. The external heat is applied by causing generator gas to circulate through suitable flues arranged round the chamber. To thoroughly heat the mass of coal, hydrogen—which may be in the form of water-gas, coal-gas, or highly superheated steam, either alone or mixed with air—is introduced into the chamber. These gases, which are introduced at a temperature above the initial heat of the chamber and its contents, mingle with the coal and rapidly effect the coking of it. The gas and by-products ("coal paraffin oil") produced in the chamber are exhausted through suitable outlets and treated in the ordinary manner. It is stated that a chamber containing five tons of coal, with a stream of gas equal to about 5,000 cub. ft. per hour at a temperature of 1,200° F., gives good results, and that the coke obtained is practically free from sulphur; also that, on account of the internal heating, that applied externally may be less than is now usual, and that the hydrogen introduced takes up nitrogen and forms ammonia. This invention may also be applied to the obtaining of by-products from shale and other carbonaceous matter, as well as from coal.—E. R. B.

*Improvement in or connected with Gas Hydraulic Mains.* J. H. R. Dinsmore, Liverpool. Eng. Pat. 5648, March 16, 1893.

The hydraulic main is divided into two compartments by a longitudinal partition plate extending from the cover plate nearly down to the bottom, so that the only communication between the two compartments is well below the level of the sealing liquor.

One compartment is open to atmospheric pressure; into the other pass the gas inlets, which dip into the sealing liquor, but only for a small depth. When there is no gas pressure on, these pipes are sealed, but when gas is passing into the main its pressure depresses the sealing liquor in the second compartment, a corresponding rise taking place in the first one, unseals the inlet pipes, and the gas passes along and out through the exit of the hydraulic main.—E. R. B.

*Retort and Apparatus connected therewith for the Purpose of Converting Coal-tar into Gas for Illumination and other Purposes.* John Smith, Upper Bangor, North Wales. Eng. Pat. 7605, April 11, 1893.

The inventor's intention is to produce permanent gas from coal-tar, the heat employed being but "little more than that necessary for vaporising the tar," while the solids left in the retort are such that they may be drawn off as pitch or converted into coke at will. An ordinary D or oval retort is employed, so set that the mouth is 3 ins. higher than the back, and is charged to a depth of 3 ins. with the coal-tar; the latter enters through a 1-in. cock, placed axially and near the top of the "ascension pipe." The vapours which accompany the gas are for the most part condensed in the hydraulic main and collected therefrom into a tank. This oil, while still warm, may most profitably be utilised as liquid fuel, but, if so desired, it may be allowed to deposit its anthracene, which it does, for the most part, upon cooling, and its naphthalene, upon further standing. The "naphtha vapours" carried over with the gas are removed in passing through the ordinary condensers.

From 1 ton of tar, 10,000–14,000 cub. ft. of gas and 6–7 cwt. of good hard coke, are produced.—E. R. B.

*Improvements in Gas Condensers.* S. Cutler, London. Eng. Pat. 11,734, June 14, 1893.

BENT, curved, or spiral tubes, rigidly connected to their end tube-plates, are employed; the expansion boxes, permitting of the varying contraction and expansion of the usually employed straight tubes, being no longer necessary.

The water enters the tubes from a common chamber, one of whose sides is the lower tube-plate (in the vertical form of condenser), and ascending them, is discharged into an upper chamber, the bottom of which is the upper tube-plate; the outlet from this chamber is such that an equal pressure is maintained in all the tubes. Sometimes the upper tube-plate carries a descending flange immersed in a water lute, the latter attached near the top of the walls of the condenser.

A further improvement is the employment of radiating plates attached, in either horizontal or inclined position, to the outside of the tubes; thereby greatly increasing the internal (cooling) surface of the condenser.—E. R. B.

*Improvements in and relating to Electric Furnaces.* H. H. Lake, London. From A. C. Girard and E. A. G. Street, Paris. Eng. Pat. 13,340, July 8, 1893.

WHEN the material to be treated is solid and a conductor of electricity, it is fed at a regular rate, as a uniform rod, through a longitudinal hole in a block of refractory material. Transverse or radial holes meet this longitudinal one and carry carbons, between which and the travelling rod, the arc is formed which is to supply the heat required. The temperature attained can be regulated by the rate of travel of the rod.

Where the material is pulverulent, it is caused to pass through the furnace in a hollow tube of carbon. This tube may either carry the material with it or be itself stationary.

Arrangements are also described for collecting the material where it is intended to be melted by the temperature arrived at; for causing the action to take place in any atmosphere desired; and for causing the whole of the

material to be acted on uniformly either by rotation of itself or by rotation of the arc—one method involving the use of a magnetic field in which the arc will, by the electric action, rotate automatically without relative movement of the parts of the apparatus.—E. T.

*Process of and Apparatus for Utilising Producer-Gas for Calcining Limestone.* A. J. Boulton, London. From A. E. Hatch, Chicago, U.S.A. Eng. Pat. 1291, January 30, 1894.

See under VII., page 636.

*Improvements in the Mantles or Hoods for Incandescent Gas Burners.* L. K. Böhm, New York, and T. C. Crawford, New Brighton, U.S.A. Eng. Pat. 4732, March 6, 1894.

The new composition material consists of about 90 per cent. of magnesium oxide, about 10 per cent. of silicic acid, and about 1 to 2 per cent. of an alkali. The silicic acid may be partly replaced by calcium or magnesium phosphate. The most suitable alkali is potassium hydrate or carbonate. The silicic acid may be used as dry powdered  $\text{SiO}_2$ , but the authors get the best results by employing gelatinous silica. The gelatinous silicic acid is obtained by precipitating a solution of water-glass with hydrochloric acid, filtering, and washing. One part by weight of the moist precipitate is well mixed with 4 parts by weight of a saturated aqueous solution of sugar, and 1 part of magnesium oxide and a small quantity of alkali gradually added with constant rubbing. In this way a plastic mass is obtained which may be moulded into the form required for the mantle or hood, or spun into threads and the mantle woven. The hoods are then burned in a baking oven. In this way a mantle or hood is produced such that, whilst consisting mainly of free magnesium oxide, it is an efficient glow-body, contains a skeleton of a double potassium and magnesium silicate giving great stability and hardness.—L. T. T.

*Appliance for Breaking down Crust in Gas Producers.* T. G. Hall, Chicago, U.S.A. Eng. Pat. 6551A, March 28, 1894.

This appliance is a kind of stamper, and consists of a rod capable of an up-and-down motion in the vertical axis of the producer, and carrying at its lower end a heavy head, while at its upper end it is attached to the following mechanism, viz.:—a flexible connection which can be wound round a drum, the shaft of which also carries a pulley and a ratchet wheel with dog; this latter can be released by the actuation of the arm of a lever placed across the path of the rising rod.

The stamper falls immediately after the upper end of its rod has thus struck the lever, unless caught by a pivoted latch lever. The latch of this last mechanism may be drawn back at any time by hand, or may be released automatically, after any arranged interval of time, by a further mechanism, worked also from the pulley shaft.—E. R. B.

the kerosene series mount by increments of 7 instead of by increments of 11, and they hold that the real atomic weight of carbon is 6, and not 12."

The material employed was Baku kerosene, of sp. gr. 0.825 at 15.5°; it was almost colourless, and had very little smell. Upon rapid distillation of two half-litre quantities it yielded, below 170° mil; from 170° to 250°, 68.8 cc.; from 250° to 300°, 20.5 cc.; the residue measuring 107 cc.

After "several months" of fractionation, full details of which operation, however, the authors do not give, 24 different liquids were obtained, besides 13 per cent. of dark-coloured residue, boiling above 290°, and of sp. gr. 0.880 at 15.5°; the two most volatile members being only present in very small quantity, while the remaining 22 were present in about equal quantities.

The authors give the following:—

TABLEAU STATEMENT OF THE CONSTITUENTS OF KEROSENE.

Fractions Nos. 1 and 2 were not obtainable in sufficient quantity for further work, and the remaining 17 fractions do not appear to have been investigated more fully.

—E. R. B.

*Examination of the Waste Liquors from the Refining of Petroleum.* R. Zdzioleki. Dingl. polyt. Journ. **290**, 258.

The waste liquor used for this examination was obtained on treatment of a mixture of crude Galician oils with caustic soda of 5 lb., subsequent to a previous treatment with sulphuric acid. After several weeks standing three separate layers had formed in the liquor. The first of these layers, constituting almost one-half of the total volume, consisted of yellow-coloured petroleum, which was siphoned off. The brown lower layer contained crystals of sulphite and sulphate of soda. These two layers were separated by a third consisting of a viscous emulsion of the oil with the brown solution. After running off the latter, direct steam was passed into this emulsion, which thereupon separated into an aqueous solution with a supernatant oily liquid. After removing the latter the two aqueous solutions were mixed and freed from mechanical impurities by filtration. On acidulating the mixed solutions, and heating, a dark brown oily liquid possessing an acid reaction separated out, the neutralised liquor at the same time becoming almost colourless. The dark oil thus obtained dissolves completely in water, although the solutions may not be quite clear. It saponifies with caustic alkalis, but these soaps also do not form clear solutions with water. This is probably due to the oil containing some unaltered hydrocarbons. The specific gravity of this oil is 0.9850 at 20° C. On heating it in a sealed tube for some hours with water at 160° C. an oil is obtained, the specific gravity of which was found to be 0.924 at 20° C., whilst the water contained a large quantity of sulphuric acid, and it also still contained some unaltered oil in solution. By saponification, and extraction of the soap solution with ether, these oils were separated into a saponifiable and an unsaponifiable fraction. The saponifiable fraction evidently consists of sulphonic acids. The unsaponifiable dark and viscid oil began to boil at 230° C., not without decomposition and evolution of sulphuretted hydrogen. Part of the distillate was still found to consist of saponifiable oils of the nature of petroleum acids. The specific gravity of the distillate was found to be 0.855 (20° C.), as against 0.868 of the undistilled oil. Part of this distillate consists of dodecyl alcohol,  $C_{12}H_{25}OH$ , besides which a hydrocarbon of the series  $C_nH_{2n}$  was observed. The above-mentioned saponifiable fraction consists chiefly of petroleum acids and sulphonic acids.—C. O. W.

*Campholene.* Guerbet. Comptes rend. **118**, 286.

The author is engaged in investigating this hydrocarbon and now points out its relation to the naphthenes of Baku petroleum.

He has obtained by heating campholene ( $C_9H_{16}$ ) in sealed tubes with hydriodic acid to 280° C., a hydrocarbon of sp. gr. 0.783 and boiling-point 132°–134° C., with the formula  $C_9H_{16}$ , which he considers to be identical with hexahydropsendocumene as extracted from Baku petroleum (see Markownikow and Oglobine, Jour. Russ. Chem. Soc. **15**, 331), while campholene itself he regards as tetrahydropsendocumene. The new hydrocarbon has all the characteristics of the benzene hexahydrides, for it does not fix bromine and is not attacked by either fuming sulphuric or nitric acids in the cold: bodies which are apparently however trinitropsendocumene and tribromopsendocumene have been obtained from it by methods described.

When campholene is repeatedly treated with fuming sulphuric acid there is obtainable, by rectification, from the supernatant hydrocarbon layer, hexahydropsendocumene identical with that described above, whilst from the acid layer is obtainable dicampholene ( $C_9H_{16}$ )<sub>2</sub>, an oily hydrocarbon boiling at 165°–168° C. with a pressure of 30 mm. of mercury and (with partial decomposition) at ordinary pressures at 266°–270° C. This dicampholene has an odour like terebenthene, and oxidises somewhat readily in the air, becoming discoloured and acquiring a resinous character. Campholene and the tetrahydrotoluene of rosin oil (Renard, Ann. Chim. Phys., 6th Series, **1**, 231, and Maquenne, *idem*, 6th Series, **28**, 279) are thus similarly affected by sulphuric acid.

It will be borne in mind that according to Markownikow (J. Russ. Chem. Soc. **22**, 275–279) the naphthenes proper are to be considered as identical with hexamethylene (hexahydrobenzene) and its homologues, and that non-napthene is probably hexahydropsendocumene.—E. R. B.

*Liquid Fuel.* G. Stockfleth. J. Soc. Arts. **42**, 616–625.

See under II., page 625.

PATENTS.

*Improvements in and relating to the Treatment of Vegetable Substances and the like for Preserving and Vulcanising the same, and for Obtaining Products of Distillation therefrom.* F. M. Grumbacher, New York. Eng. Pat. 10,979, June 5, 1893.

In wood-preserving and hardening processes where high temperatures and high air pressures are used, the fibre sometimes becomes partially carbonised. The patentee proposes to replace the air in the air-tight receptacles by carbonic acid at pressures varying from normal to 10 atmospheres. He finds that then carbonisation is effectually prevented, a higher temperature may be safely employed, and better results obtained.—L. T. T.

*Improvements in the Treatment of Waste from Gas Liquor to obtain Useful Products therefrom.* H. W. Crowther, West Bromwich, Stafford. Eng. Pat. 11,964, June 17, 1893.

See under VII., page 635.

IV.—COLOURING MATTERS AND DYES.

*On some Derivatives of the Oxazine and Euxhodine Series.* C. Lauth. Comptes rend. 1894, **118**, 473–476.

By substituting di-ethyl or di-methylmetamidophenol for dimethylaniline in the preparation of methylene blue by oxidation of amido dimethylaniline thiosulphonate in presence of dimethylaniline, the author sought to produce

a hydroxylated methylene blue, or, failing this, to ascertain the relative stability of the groups  $\text{S} \cdot \text{SO}_3\text{H}$  and  $\text{OH}$ . Hydrochloride of nitrosodimethylaniline, reduced with zinc and hydrochloric acid, was largely diluted with water, treated with sodium thiosulphate and bicarbonate, and soda crystals, and, after the addition of diethyl-amido-phenol dissolved in acetic acid, was oxidised with bichromate. The liquid was then strongly blue, and on boiling threw down a precipitate, which was filtered, washed, and purified by boiling with very dilute hydrochloric acid, precipitating with sodium chloride, again precipitating by sodium and zinc chlorides, this time from solution in very dilute boiling sodium carbonate, and finally recovering the pure solid by evaporation from alcoholic solution. This substance contains no sulphur, and cannot therefore be a thionine; it is an oxazine having the formulæ—

Its distinguishing characteristics are as follows:—It has a blue-violet colour, and dyes silk and wool, or cotton prepared with tannin, that shade. It dissolves in water or alcohol, and to a slight extent in sodium carbonate solution, with a red-violet colour; it is more soluble in ammonia, from which solution ether fails to extract an appreciable quantity. It dissolves in strong sulphuric acid, giving a very red-violet, in strong hydrochloric acid an olive green, and in dilute acids a pure blue solution. A simple mixture of amido dimethylaniline and diethyl-amido-phenol does not yield this body, but produces a blue substance in the cold, which is apparently an indamine, being soluble in alkalis, altered by acids, destroyed by boiling with water (yielding a red substance), and converted into safranine by boiling with aniline acetate in presence of bichromate. It has not yet been transformed into an oxazine, but its formation throws light on that of the oxazine. Oxidation of a mixture of mercaptan and diethyl-amido-phenol produces a thiosulphated indamine, which, on boiling with water in the presence of an oxidising agent reacts according to the equation—

In support of his views as to the constitution of the believed oxazine, the author instances the production of a tetramethylated curholine, according to the equation—

by the oxidation of metanido-dimethylaniline in the presence of paranido-dimethylaniline thiosulphonate. After half an hour's boiling, this solution being extracted with very dilute soda, precipitated by sodium and zinc chlorides, yields a violet-red eurhodine, becoming blue in solution with hydrochloric, and green with sulphuric acid, and returning to its original tint on dilution, which tint is unaltered by ammonia.

—W. G. M.

*The Blue Coloration produced by Leuco-auramine in Contact with Acids.* A. Rosenstiehl. Comptes rend. 118, 741—743.

In a recent paper (Bull. Soc. Chim. 11—12, 213) the author has expressed his views as to the cause of colour in derivatives of triphenylcarbinol (this Journal, 1893, 748, and 1894, 382). He supposes that the molecule contains

two radicals of opposite chemical functions, one of which is attached to the central carbon atom and the other in the para position in two of the three phenyl groups. Most cases can be explained on this hypothesis, an exception, however, being the blue colouring matter from leuco-auramine described by Gräbe (Ber. 20, 3261; this Journal, 1888, 30), and to which he gave the following formulæ:—

*Leuco-auramine.*

The author observes that tetramethylbiamido benzhydrol behaves in the same way towards acids that leuco-auramine does, and is of opinion that leuco-auramine does not exist in the blue form, but that the body produced by the action of acids on it is the chlorhydride of tetramethylbiamido-benzhydrol—

which has a blue colour, and when represented by this formula also accords with the hypothesis he has put forward.

—T. A. L.

*The Carboxylic Acids of Dimethylaniline.* C. Lauth. Bull. Soc. Ind. Mulhouse, 1894, 24—35.

THE author has investigated the influence of the carboxyl group in the *o*-, *m*-, and *p*-positions in dimethylaniline in certain reactions, and gives the preparation of the first of these compounds (dimethyl-anthranilic acid), as it does not appear to have been hitherto prepared. It is obtained by heating for three hours on the water-bath, 10 grms. of *o*-amido-benzoic acid, 7 cc. of caustic soda solution of 36 B., 24 grms. of methyl iodide, and 30 cc. of 95 per cent. alcohol. The crystals, which separate on evaporating the alcohol, are purified by recrystallisation from water. That the substance has the constitution  $\text{C}_6\text{H}_3\text{N}(\text{CH}_3)_2\text{CO}_2\text{H}$  is proved by treating it with alcoholic soda and reprecipitating with an acid, when it remains unaltered. An attempt was made to prepare the body by heating the hydrochloride of *o*-amido-benzoic acid with methylic alcohol, but  $\text{CO}_2$  was given off. Another method attempted was, heating salicylic acid with dimethylaniline, but in this case also  $\text{CO}_2$  was evolved, and in a similar manner the oxidation of dimethyl-*o*-toluidine with potassium permanganate did not yield the substance required. The mother-liquor, obtained in the method given above, when evaporated, gives crystals of a quaternary compound, which can also be obtained directly by the action of 3 molecular proportions of methyl iodide on equimolecular proportions of anthranilic acid and soda. *Dimethyl-*o*-amidobenzoic acid* crystallises in long colourless prismatic needles, melting at 175° C. after sublimation, but if crystallised from water or benzene it melts at 179° C. It dissolves in 250 parts of boiling and 500 parts of cold water, and is very soluble in alcohol, ether, and hot benzene. All these solutions have a blue fluorescence. It sublimes in beautiful needles, but undergoes partial decomposition into dimethylaniline and a violet-coloured substance, and gives dimethylaniline when heated with lime. It gives salts with acids and bases, behaving like an amido acid, but a nitroso compound has not been obtained. The colours obtained from it by combining it with diazo compounds are yellow, orange-red, and brown, but are of no particular importance. Attempts to obtain a closed chain compound of the indigo type by means of dehydrating agents, either with or without oxidising agents, were unsuccessful. By the action of oxidising agents such as bleaching powder, bichromate, or ferric chloride, greenish or violet precipitates are obtained. Lead peroxide in presence of acetic acid gives a greenish-blue substance insoluble in water and alcohol, and decolorised by alkalis. The decolorised liquor on fresh treatment with  $\text{PbO}_2$  in presence of acetic acid reproduces the greenish-blue substance. The author refers

to a similar reaction he described with the oxidation product of tetramethyl-benzidine, and he believes that a benzidine derivative is formed in this case also. With chloride of copper, or preferably chloranil, a beautiful violet-red colouring matter is obtained from the dimethyl-*o*-amido-benzoic acid. One part of the acid is heated with  $1\frac{1}{2}$  to 2 times its weight of chloranil to 100–110° C. The mass gives off water, and after the reaction is complete the melt is extracted with benzene and the residue dissolved in sodium carbonate and precipitated with sulphuric acid. It is further purified by extracting with alcohol, and after evaporation, the residue is dissolved afresh in sodium carbonate and precipitated with salt. The final purification consists in dissolving it in sodium carbonate, precipitating with sulphuric acid, drying, and washing with boiling ether. The compound thus obtained being 60 per cent. of the weight of the acid taken, is a greenish-bronze coloured substance, insoluble in water, soluble in alcohol, and having in general the properties of the triphenyl-methane colouring matters. Its alcoholic solution is decolorised by zinc and acetic acid, and the leuco-compound obtained regenerates the colouring matter on oxidation with  $\text{PbO}_2$ . It differs, however, from the triphenylmethane colouring matters hitherto known, as it is soluble in alkalis and reprecipitated by acids. According to the analysis, which gave numbers corresponding to  $\text{C}_{22}\text{H}_{20}\text{N}_2\text{O}_2$ , or to  $\text{C}_{20}\text{H}_{18}\text{N}_2\text{O}_2$ , it may be regarded as penta- or tetra-methyl rosaniline tricarboxylic acid or as a mixture of the tetra-, penta-, and hexa-methyl derivatives. As regards its dyeing properties, it has an affinity for metallic mordants, especially chromium oxide, on cotton, and also dyes wool and cotton mordanted with tannin like a basic dyestuff, and its alcoholic solution does not dye silk excepting in the presence of acetic acid. The shades obtained in spite of the four or five methyl groups are those of a partially alkylated rosaniline, the effect of the three carboxylic groups being to considerably reduce the product. Attempts to prepare the same substance by the action of carbon tetrachloride in presence of aluminium chloride were unsuccessful, and this was also the case with benzylidene chloride. By heating the substance with acetic anhydride in presence of sodium acetate it is decolorised, but the colour reappears on boiling with hydrochloric acid. The dimethylantranilic acid will also yield the leuco-compounds of colouring matters on condensation with tetramethyldiaminobenzhydrol (benzhydrol is diphenyl carbinol) and with benzaldehyde, which on oxidation give the colouring matters themselves, that from the former giving a violet and from the latter a blue. Meta-nitrobenzaldehyde gives a rather greenish blue. All these colouring matters dye wool, silk, and cotton mordanted with tannin, and by virtue of their carboxyl groups will also combine with metallic mordants. Condensation products have also been obtained with formaldehyde in presence of sulphuric acid, but no colouring matters have been obtained therefrom. As mentioned above, the mother-liquor from the preparation of the dimethyl-*o*-amidobenzoic acid deposited crystals on standing. These consisted of the sodium salt of the methyl iodide of the above acid, and have the formula  $\text{C}_{10}\text{H}_4\text{N}(\text{CH}_3)_3\text{I} \cdot \text{CO}_2\text{Na}$ . The substance is very easily soluble in water, dissolves in 2.8 parts of alcohol, and fuses below 100° C. On decomposing with hydrochloric acid it yields the corresponding acid, which separates in long crystals melting at 175° C., and is very soluble in water, alcohol, and acetone, but insoluble in benzene and ether. When decomposed with silver oxide it yields a compound which has all the properties of an ammonium base, and when the base is heated to about 200° C. it decomposes into carbonic acid, methyl alcohol, and dimethylaniline. It gives a characteristic orange-red colour with lead peroxide in presence of acetic acid, and when heated with chloranil it yields a violet which appears to be identical with the carboxylated tetramethyl violet described above. The author has also investigated the behaviour of *p*- and *m*-dimethylamido-benzoic acid towards oxidising agents, and finds that neither gives colouring matters, and although he obtained condensation products from the *p*-acid with benzhydrol (diphenyl carbinol) and benzaldehyde, he showed that the substances

produced were methyl violet and malachite green, that is to say, that the carboxyl group had been eliminated. In the case of the *m*-acid no colouring matters were obtained on oxidation, and the condensation product with benzhydrol only gave a very small quantity of hexamethyl violet, which probably was due to a decomposition of the hydrol itself. In addition to the three acids mentioned, the author has also investigated the dimethylamidosalicylic acid, corresponding to the 1,2,5-nitro-salicylic acid melting at 226–228° C., as this acid ought to give valuable mordant colouring matters. Attempts to methylate the amido acid directly, proved unsuccessful, and he only succeeded by Griess' method of preparing the periodide of the betan of salicylic acid, converting this into the dimethyl ether, and then saponifying the product. He obtained in very small yield, a crystallised acid melting at 226° C., which gave no coloration on oxidation, nor was it possible to condense it with benzaldehyde. Benzhydrol gave a very blue violet, which, however, would not dye on metallic mordants. The acids described in the paper give the following characteristic tests when their solutions are treated with lead peroxide in presence of acetic acid. *o*-Dimethylamidobenzoic acid gives a dark greenish-blue precipitate, the *m* acid gives a fugitive dark reddish-brown coloration, the *p*-acid a brown coloration changing to violet, and the dimethylamidosalicylic acid gives a reddish-orange coloration changing to brown. The following conclusions are deduced from the results:—

1. The colouring matters obtained from dimethylaniline containing a carboxyl group in the ortho position, have very different chemical and tinctorial properties from those obtained from dimethylaniline.

2. The position of the carboxyl group determines the course of the reaction: if it is in the ortho position, carboxylated colouring matters are obtained; if in the para position, the carboxyl group is eliminated, and the colouring matters produced are identical with those obtained from dimethylaniline; whilst if the carboxyl group is meta to the dimethylamido group, the property of forming colouring matters will have almost entirely disappeared.—F. A. L.

*The Titration of Aniline and other Organic Bases with Methyl Orange.* G. Lange. Chem. Ind. 16, 490.

See under XXIII., page 667.

## PATENTS.

*The Manufacture and Production and Application of New Colouring Matters or Dyes from Naphthalene.* J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 10,996, June 5, 1893.

When naphthalene is converted into its dinitro-compound, a mixture is obtained which consists of the 1.1' and 1.4' derivatives. Of these, only the 1.4' has hitherto been employed in the manufacture of naphthazarine (Eng. Pat. 7833 of 1887; this Journal 1888, 431), and for the preparation of 1.4' naphthylene diamine, whilst the 1.1' derivative has been a waste product. According to the present specification, the 1.1' dinitronaphthalene can be converted into valuable black colouring matters for cotton by the action of alkaline reducing agents. Three products are described, and designated A, B, and C. A is prepared by reducing 1.1' dinitronaphthalene in a boiling alkaline solution with grape sugar, when a violet precipitate having a metallic lustre separates out. It gives black to violet-black shades, which are best obtained by producing them on the fibre directly. B is formed by using a rather dilute solution of an alkaline sulphide, and is precipitated from this solution by the addition of an acid. It is insoluble in sodium carbonate solution, and is dyed on cotton, linen, jute, and the like by using a strong bath containing up to 25 per cent. of sodium carbonate, and adding grape sugar or a similar reagent. If a more concentrated solution of sodium sulphide be employed, there results the dye C, which differs from A and B in being soluble in sodium carbonate, and can be fixed

on cotton, linen, or jute by boiling in a strong bath of sodium carbonate as with B, but without the addition of grape sugar. The specification contains a table showing the behaviour of these dyes to different reagents.—T. A. L.

*Improvements relating to the Production of Colouring Matters.* A. Ashworth and J. Burger, Bury. Eng. Pat. 11,556, June 13, 1893.

THE action of sulphurous acid and its salts on nitroso- $\beta$ -naphthol produces an amidonaphthol sulphonic acid, but by the moderate action of bisulphites on the compound an intermediate product is obtained which is the subject matter of the present patent. One kilo. of nitroso- $\beta$ -naphthol, preferably as a paste, is mixed with 2 kilos. of sodium bisulphite solution of about 6% T., and heated to about 25° to 30° C. The melt is removed from the water-bath when the reaction commences, and the temperature rises spontaneously about 20°. The whole mass after some time solidifies to a paste of greyish-white crystals of the new compound. It is easily soluble in water and is decomposed by caustic soda regenerating nitroso- $\beta$ -naphthol. It can be used directly for printing and dyeing, giving green shades with iron and brown shades with chromium mordants. The new compound can also be condensed with hydroxy-carboxylic acids, such as gallic acid, or with tannin, giving condensation products which dye brown on chromium mordants and are said to be fast to light and soap. A further property of the new compound is that it will combine with diazo compounds, the following example being given. The diazo compound from 14.3 kilos. of  $\alpha$ - or  $\beta$ -naphthylamine is combined with 25.9 kilos. of the new compound dissolved in sodium carbonate. The mixture is allowed to stand and the colouring matter salted out, filter-pressed, and dried. The new azo compounds form brown or reddish-brown powders, are easily soluble in water, and dye brown to reddish-brown shades on chromium mordants.—T. A. L.

*The Manufacture or Production of Dyestuffs.* II. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 11,892, June 16, 1893.

THIS is an extension of Eng. Pat. 8898 of 1893 (this Journal, 1894, 511), and refers to a more general method for producing the colouring matters there described. The method employed in the patent referred to for the production of basic azine dyestuffs or their sulphonic acids from the symmetrical or mixed dialkyl 1:3-naphthylene diamines or their sulphonic acids, was by condensing them with the nitroso derivatives of secondary or tertiary aromatic amines or amidosulphonic acids. These latter, it has now been found, can be replaced by compounds which act in a similar manner, as, for instance, quinone dichloroimide or azo compounds from diazo derivatives combined with primary, secondary, or tertiary amines or their derivatives. The same or similar dyestuffs can also be obtained by oxidising the alkylated 1:3-naphthylene diamines together with alkylated  $p$ -diamines or their sulphonic acids. These results are modified according to the nature of the solvent or diluent employed. Thus, for instance, a different product is obtained in a condensation as described above if a neutral or basic solvent is used, to that formed if an acid be employed. In the latter case, the amine liberated from the azo compounds combines with the acid, forming a salt which is incapable of acting further on the resulting dyestuff. As an example, if azo-benzene and di- $p$ -tolyl-1:3-naphthylene diamine are heated in glacial acetic acid solution and the product is subsequently sulphonated, a dyestuff of yellower shade is obtained than that produced when phenol is used as a solvent. All the dyestuffs produced according to this invention which do not contain sulphonic acid groups and are insoluble or sparingly soluble, may be sulphonated in the usual manner. The colouring matters obtained are principally blues and violets, and dye cotton mordanted with tannin.—T. A. L.

*Production of Azo Colours.* T. R. Shillito, London. From J. R. Geigy, Basle, Switzerland. Eng. Pat. 11,902, June 16, 1893.

THIS is an extension of Eng. Pat. 15,692 of 1892 (this Journal, 1893, 755), and describes the preparation of colouring matters by combining the diazo compounds of  $\alpha$ - $p$ -amido-phenol disulphonic acid or of  $p$ -amido-phenol sulphonic acid with pyrogallie acid, the following quantities being employed:—30 kilos. of  $\alpha$ - $p$ -amido-phenol disulphonic acid are dissolved in 300 litres of water mixed with 50 kilos. of ice and diazotised by adding 15 kilos. of hydrochloric acid of 21° B. and 7 kilos. of sodium nitrite. The diazo compound is precipitated by adding 50 kilos. of salt and is mixed with 50 kilos. of ice. A solution of 15 kilos. of pyrogallie acid in 20 litres of water is then added, and immediately afterwards a solution of 18 kilos. of sodium carbonate in 60 litres of water. After 12 hours, 50 kilos. of 40 per cent. acetic acid are added, and the paste thus produced may be used directly for printing, or the colouring matter may be filtered off and dried.—T. A. L.

*Improvements in the Production of Colouring Matters Dyeing with Mordants.* W. E. Heys, Manchester. From Sandoz and Co., Bâle, Switzerland. Eng. Pat. 3886, February 23, 1894.

WHEN  $\beta$ -naphthoquinone 4-sulphonic acid reacts with an aromatic compound containing a free amido group, the sulphonic acid group is eliminated. For instance, with aniline and 1:2-naphthoquinone 4 potassium sulphonate the following reaction takes place—

and a bright vermilion precipitate of  $\beta$ -hydroxy- $\alpha$ -naphthoquinone is formed. The same reaction takes place with  $p$ -diamines, derivatives of indophenol being formed. Thus  $p$ -amido-dimethyl aniline yields  $\beta$ -hydroxy-indophenol as a blackish-violet precipitate insoluble in water. By using the thiosulphonic acids of the asymmetrically substituted  $p$ -diamines or  $p$ -diamine sulphonic acids, thiosulphonic acids of the  $\beta$ -hydroxy-indophenols are formed, which are easily converted into thiazine colouring matters according to the following equation:—

THIS conversion can be performed by boiling the aqueous solutions of the hydroxy- and sulpho hydroxy-indophenol thiosulphonic acids with zinc chloride. By printing these acids in presence of chromium mordants on cotton fibre and subsequently steaming under pressure, the thiazine colouring matter is developed and converted at once into its insoluble chromium lake, which is fast to washing, acids, and alkalis. The thiazine colouring matters themselves are obtained from the indophenol thiosulphonic acids by boiling their aqueous solutions with caustic alkalis or by adding them to concentrated monohydrated or fuming sulphuric acid. The first method is used preferably when sulphonic derivatives of the hydroxy-indophenol thiosulphonic acids are employed, whilst the second method is more applicable to the non-sulphonated derivatives since after the conversion into the thiazine the product can be sulphonated by adding sulphuric acid containing a higher percentage of anhydride. The conversion in both cases takes place at 50° C., and the sulphonation at 70°—80° C. until a sample dissolves in sodium acetate solution with a pure blue colour. As an example of the method employed for developing the colour on the fibre, 30 kilos. of hydroxy-indophenol sodium thiosulphonate (prepared by mixing aqueous solutions of 1:2-naphthoquinone 4-potassium sulphonate and  $p$ -amido-dimethylaniline sodium thio-sulphonate) are mixed at 70°

C. with 300 litres of water and 340 kilos. of tragacanth gum thickening. After cooling, 30 kilos. of 40 per cent. acetic acid and 50 kilos. of chromium acetate of 20° B. are added and the whole sieved, when it is used for printing on cotton previously oiled. The fabric so treated is then steamed for  $1\frac{1}{2}$  to 2 hours at a pressure of  $\frac{1}{2}$  to 1 atmosphere. This produces an indigo blue, which is brightened by chalk and soaping. The sulpho-hydroxy-indophenol thiosulphonic acid from sulpho-*p*-amido-ethyl-benzylaniline thiosulphonic acid dissolved in 50 times its weight of water and boiled with a quantity of caustic soda solution of 40 per cent. equal to  $\frac{1}{10}$  of the volume of the water, is easily converted into the corresponding thiazine sulphonie acid, which can be separated from the liquor made acid first with hydrochloric and finally with acetic acid, in the form of its acid salt, by adding common salt. The following example shows the method employed when sulphuric acid is used for the conversion:—30 kilos. of hydroxy-indophenol thiosulphonic acid from *p*-amido-diethylaniline thiosulphonic acid are added to 90 kilos. of sulphuric acid monohydrate and heated to 30° C. for 2 hours, and subsequently for 2 hours more to 50° C. The conversion into the thiazine is then complete, and in order to sulphonate the product, 90 kilos. of 70 per cent. anhydride are added in the cold. The melt is then heated to 80° C., until the sulphonation is complete and the sulphonie acid is separated by pouring the melt into ice-cold water, when the precipitate is filtered off, converted into the sodium salt by boiling with sodium acetate, salted out, filter-pressed, and dried. It dyes unmordanted wool bluish-violet from an acid bath and gives blue and greenish-blue shades on chromium mordants fast to acids, alkalis, and light.—T. A. L.

*Manufacture of a New Dioxynaphthalene-mono-sulpho Acid and of Colouring Matters therefrom.* H. Imray, London. From "The Basle Chemical Works Bindschedler," Basle, Switzerland. Eng. Pat. 4629, March 5, 1894.

The substance referred to is obtained by fusing 50 kilos. of the sodium salt of hydroxynaphthoic disulphonic acid,  $(1,2,4,2')C_{10}H_4(OH).CO_2H.(SO_3H)_2$ , with four times its weight of caustic soda at 230°–290° C. for a few hours. The melt is then dissolved in water, acidulated with a mineral acid, neutralised with sodium carbonate, and filtered. The liquor thus obtained contains the new (1,7,4) dihydroxy-naphthalene sulphonie acid, and has a bluish-violet fluorescence. It can be used directly for the production of colouring matters by combining it with tetrazo compounds. For instance, a colouring matter which dyes unmordanted cotton a greenish-blue is obtained by diazotising 24 kilos. of dianisidine dissolved in 52 kilos. of hydrochloric acid and 250 litres of water with 14 kilos. of sodium nitrite in 50 litres of water. This solution is then poured into a solution containing 20 kilos. of sodium carbonate and 27 kilos. of the sodium salt of the new acid. After stirring for some time the intermediate compound is formed, and a second quantity of the solution of the new acid equal to the first is then added. When the combination is complete, the liquor is raised to 100° C., and the colouring matter is filtered off and dried. Other tetrazo compounds can, of course, be used, and the shades produced are reds, browns, violets, and blues.—T. A. L.

*Manufacture of a New Dioxynaphthoic-mono-sulpho Acid and of Colouring Matters therefrom.* H. Imray, London. From "The Basle Chemical Works Bindschedler," Basle, Switzerland. Eng. Pat. 4630, March 5, 1894.

By carrying out the fusion described in the preceding specification at a lower temperature, viz., at 180°–200° C., a new dihydroxy-naphthoic monosulphonie acid is obtained, which, after dissolving the melt in water and neutralising with a mineral acid, separates as a white precipitate. This compound, like the preceding one, will combine with tetrazo bodies, such as tetrazo-diphenyl and its homologues, the ethers of tetrazo-hydroxy-diphenyl, and of tetrazo-dihydroxy-diphenyl, tetrazo-stilbene, and tetrazo-azobenzene and its homologues. The tetrazo compound from 21 kilos. of

tolidine, 500 litres of water, 55 kilos. of concentrated hydrochloric acid, and 14 kilos. of sodium nitrite, is added to a solution of 35 kilos. of dihydroxy-naphthoic sulphonie acid and 20 kilos. of soda ash. When the formation of the intermediate compound is complete, a solution of 25 kilos. of the sodium salt of *a*-naphthol-*p*-sulphonie acid is run in and the whole stirred for 24 to 48 hours. The liquor is then boiled and the dyestuff salted out, filtered off, and dried. It dyes unmordanted cotton a violet-blue.—T. A. L.

*Manufacture of New Amido-Bases and of New Colouring Matters therefrom.* R. Koreff, Pele Tyrolka, Prague, Bohemia. Eng. Pat. 5143, March 12, 1894.

THE bases are obtained by condensing *o*-toluidine, *a*-naphthylamine, *o*-tolidine, or *o*-dianisidine with formaldehyde in presence of sulphuric acid. By this means the amido groups are left intact, and the new base, for instance, from tolidine, has the constitution—

This substance is obtained by dissolving 42.4 kilos. of *o*-tolidine in 400 kilos. of sulphuric acid of 66° B., and adding 7.5 kilos. of 40 per cent. formaldehyde. The reaction is complete when the melt does not smell of formaldehyde and a sample dropped into water no longer gives a precipitate of the sparingly soluble tolidine sulphate. The melt is then poured into 2,500 litres of cold water and gives a clear yellow solution which, when tested with nitrite, shows that the amido groups are intact. Two isomeric bases are said to be formed in this reaction, one giving a sparingly soluble and the other an easily soluble sulphate. Both, however, are easily soluble in dilute sulphuric acid. On adding an alkali to the solution obtained above, the two bases can be fractionally precipitated. All the bases obtained in this way are easily diazotised, and can be combined with various components in the usual manner.

—T. A. L.

*Manufacture of Yellow and Orange Colouring Matters from  $\beta$ -resorcylic Acid.* F. Muhlert, Pele Tyrolka, Prague, Bohemia. Eng. Pat. 6004, March 22, 1894.

THE colouring matters are produced by combining diazotised *m*- or *p*-nitraniline with  $\beta$ -resorcylic acid—

in an acid solution. The dyestuffs are for use with chromed wool or cotton, and are said to give shades fast to light and washing. A solution of 15.4 kilos. of  $\beta$ -resorcylic acid and 13.6 kilos. of sodium acetate in 100 litres of water is poured into the diazo solution from 13.8 kilos. of *m*-nitraniline. The combination takes place slowly and the colouring matter precipitates in yellow flakes. It dyes a pure yellow on chromed wool and cotton and also on wool which has been mordanted with alum and tartar. The colour from *p*-nitraniline gives a more orange shade.

—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

### PATENTS.

*Improvements in the Extraction and Preparation of the Fibres of Rhea and other Grasses and Fibrous Vegetables.* H. C. Fellowes and W. R. Crozier, London, and H. Ferguson, Leytonstone. Eng. Pat. 6584, March 28, 1893.

This invention deals with the preparation of rhea, china-grass, and similar fibrous substances for the spinning and weaving processes, &c. The so-called "ribbons" of rhea are laid by hand lengthwise and evenly in a suitable open-work receptacle, which has the form of a shallow tray and

is provided with a number of parallel ridges. The fibrous material is held in place by means of an open-work cover. The material thus arranged is boiled for about three hours (the time varying, however, according to the condition of the fibres and the strength of the solution) in an alkaline solution, e.g., caustic soda, the proportion being from 90 to 168 lb. of NaHO to 5,000 gallons of water. The patenters regard it as an important feature of their invention that by this boiling process the material is prepared for the separation of the extraneous coatings from the fibres. This separation is effected by the immersion of the boiled material in a tank of warm water (of about 160° F.) for 2–6 hours. Then the fibres are rinsed in cold water, and finally treated for a short time with a cold mixture of vegetable oils, alkalis, and water in order to further improve the appearance of the material.—H. S.

*Improvements in Scouring, Degreasing, and Cleansing Wool, and in Apparatus therefor.* F. N. Turney, Nottingham. Eng. Pat. 8179, April 22, 1893.

THE greasy wool is placed in thin layers in perforated boxes which are introduced into an airtight cleansing apparatus which is provided with three chambers for the receiving, degreasing, and drying of the material. The degreasing chamber is provided with a number of shallow tanks arranged in different heights, and having sloping bottoms. These tanks contain a volatile scouring liquid, in which the boxes with the wool are dipped a number of times, clean solvent being supplied to the upper or last tank and passed from this to the next lower one in a continuous cycle, so that as the wool becomes cleaner it is washed in cleaner solvent. The wool thus readily parts with gritty matters, impurities, and fatty matters. The volatile solvent, when dirty, is distilled off, condensed (together with the vapours of the drying chamber), and re-used. Then the wool is dried in the drying chamber, and finally washed with warm water, or soap and water, in order to further purify the material and to improve its colour.—H. S.

## VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

*Dyeing with Glucosides and Rhamnosides.* E. Schunck and L. Marekewski, J. Soc. Dyers and Colourists, 1894, 95.

It is known that the tinctorial power of plant extracts is considerably increased by boiling with acids, this being due to a decomposition of the glucoside or rhamnoside present. When glucosides are directly employed in dyeing, a simultaneous hydrolysis of the glucoside has been assumed. The experiments of the authors confirm this assumption and prove conclusively that the mordant contained in a hank of cotton yarn is capable in most cases of bringing about a decomposition of the glucoside. The experiments were carried out with 1 per cent. solutions of ruberythric acid, ditisein, rutin, and quercitrin. In one series, cotton hanks mordanted with iron were dyed in the liquors at the boil; the other series were similarly boiled, but without insertion of the mordanted cloth. The spent liquors were then tested for sugar by two distinct methods. The liquors from the hanks dyed in rutin, quercitrin, and ditisein showed the presence of free sugar; that from the ruberythric acid showed no sugar, and the hank was only tinged, not dyed. The liquors containing no hanks did not in any case show a formation of sugar, proving that boiling with water alone had effected no decomposition.—W. E. K.

*The Fading of Colours.* A. Dufton. J. Soc. Dyers and Colourists, 1894, 90.

DÉPIERRE and Clouet have shown that the rate of fading of colours under the influence of light is not simply a function of the wave length of the incident light, but depends on the

colour of the material exposed. Thus they have shown from experiments made with various coloured glasses that red and blue colours are most powerfully affected by light which has passed through yellow glass, whilst other shades fade most rapidly under blue glass. Theoretically it would be expected that it is the absorbed radiation which brings about the fading of a colour, since it is only the absorbed rays which can supply the energy requisite for the decomposition of the colour molecules, and that consequently each colour would be most rapidly affected by those rays for which it shows the strongest absorption, and the author's experiments confirm this view. Thus, a pattern dyed with picric acid is protected as efficiently by a gelatin plate dyed with picric acid as it is by a black opaque screen. On the other hand, wool dyed Victoria blue or cotton dyed diamine sky-blue and exposed under a screen dyed a very full shade of orange G (which absorbs the whole of the more refrangible rays), fades almost as quickly as if uncovered, the screen still transmitting these rays which the blues are capable of absorbing.

In general, patterns exposed under screens dyed with the same colour are not so perfectly protected as is the case with a yellow like picric acid, as most colours are capable of absorbing light of all wave lengths (*i.e.*, they become black when sufficiently concentrated) and hence patterns dyed with such colours can only be perfectly protected by a black screen.

The author explains from these considerations the reason why a colour is relatively faster when dyed a dark than a light shade, the superficial or topmost layers of colour filtering off from the lower portions those rays to which the colour is most sensitive, and consequently the destruction of the colour goes on slowly layer by layer. Similarly in a mixed shade a fast colour protects a fugitive colour if the former absorbs those rays to which the latter are sensitive. The author explains the protective action of copper salts on certain colours as being due to the formation of a copper-lake and not to any filtering off of the actinic rays by the copper salt. He does not suppose the fading of colours in presence of light to be due to the formation of ozone or peroxide of hydrogen, but to the action of atmospheric oxygen under the influence of the absorbed rays.—W. E. K.

*A Process for Dyeing Wool with Fast Colours.* C. D. Abel, London. From Farbwerke vorm. Meister, Lucius, and Brünig, Germany. Eng. Pat. 9371, May 10, 1893.

Wool dyed with azo-colours derived from  $\alpha$ -naphthol, are subsequently treated with chromic acid, by which treatment the shade is modified and its fastness very greatly increased.—W. E. K.

*Improvements in Vats for Dyeing Indigo Blues and the Like.* J. Grime, Bushy, N.B. Eng. Pat. 12,076, June 20, 1893.

THE arrangements and processes generally used in dyeing indigo are followed, but in addition each vat is provided with a smaller subsidiary vat into which, from time to time, the sediments or bottoms from the larger vat are pumped, and, after settling, the clear liquor is run back again into the main vat. It is claimed that in this way a practically clear working vat is obtained, which renders the process of dyeing very simple and regular.—W. E. K.

*Improved Process for Dyeing Textile Materials.* H. B. Lake, London. From E. Michaelis and Co., Cottbus, Germany. Eng. Pat. 15,983, August 5, 1893.

TEXTILE materials dyed indigo in the hyposulphite vat are, in lieu of the usual airing, passed into water containing acetic or other acid, or a salt having an acid reaction, in the presence of which the oxygen dissolved in the water oxidises the indigo-white to indigo-blue.—W. E. K.

*Improvements in the Method of Bleaching Cotton Cloths and other Materials, and in Apparatus employed therein.* G. A. J. Schott, Bradford. Eng. Pat. 15,531, August 16, 1893.

THE operations, which resemble generally those ordinarily followed in the bleaching of cotton goods, are carried out consecutively in a kier (the construction of which is described) without the removal of the goods therefrom.

—W. E. K.

## VII.—ACIDS, ALKALIS, AND SALTS.

*The Fusibility of Mixtures of Isomorphous Salts.* H. Le Chatelier. Comptes rend. 1894, **118**, 350—352.

THE author refers the present incomplete knowledge of the laws governing solution, in part to the influence of Proust's ideas, which has deterred chemists from studying phenomena that are not governed by the laws of definite proportion, and in part to the abnormal molecular constitution presented by the solvents (water, alcohol, and acetic acid) usually employed in laboratories. He proposes to approach the subject from the purely experimental side, and, leaving aqueous solution for the present, to study the mutual solvent action of salts, or the fusibility of mixtures of such bodies. Acting on the assumption that there is no real distinction between the solvent and the body dissolved, and that conglomeration and crystallisation are identical phenomena, he has fused mixtures of truly isomorphous salts, in which the ratio of the molecules of one component to the whole number in the mass is accurately known, and has noted the temperature at which crystallisation is first observed. These results are embodied in the following table, in which the ratio representing the number of molecules of the italicised constituent of any mixture to the whole number of molecules present is given in one line, and the crystallisation temperature of that mixture is stated immediately beneath it.

$K_2CO_3 + Na_2CO_3$ .....	0	0.20	0.38	0.55	0.65	0.79	1.0	..
	860°	770°	715°	690	700	740°	820°	..

	640	610°	590°	580	630°	680°	740°	..

These combinations were chosen from bodies shown by Wyrouboff to be isomorphous, or believed to be so from chemical analogy. In graduating the pyrometer, the melting-point of gold was taken as 1,045°. The fusion was made in a platinum crucible, and the mass was stirred while cooling with the end of the thermo-electric couple.

—W. G. M.

*Action of Water on Bicalcium Phosphate.* A. Joly and E. Sorel. Comptes rend. **118**, 738—741.

THE authors have studied the action of boiling water on secondary calcium phosphate, determining the conditions under which the reversion to the more basic salt takes place, and preface their results by a short account of some similar decompositions. The primary or secondary phosphates other than the salts of the alkalis are, it is known, converted into more basic salts by the action of water. In the case of primary or secondary silver phosphate cold water causes a conversion into the tertiary salt. With the phosphates of the alkaline earths the primary are converted by cold water into secondary salts, but require to be heated to 100° C. or higher, in order to effect the conversion into the tertiary salts. The reaction can be still further complicated by a change of the dibasic salt into another of the same composition, but in a different state of

hydration. This is the case with crystallised bicalcium phosphate  $Ca_2H_2(PO_4)_2 \cdot H_2O$  which, when heated to 100° C. in presence of water can give either an amorphous trialcium salt or a crystallised anhydrous bicalcium salt, the extent of the change depending upon the amount of water present. The reaction can be followed step by step, and the alteration in the product determined by analysis and by microscopical examination in polarised light. When crystallised bicalcium phosphate is thrown into 100 times its weight of water the crystals rapidly devitrify, and the mother-liquor, which is acid to litmus paper and neutral to methyl orange, contains a primary phosphate. After boiling some minutes the ratio of lime to phosphoric acid in the amorphous product formed was 2.86, and at the end of 1½ hours, when the deposit was partly crystalline, the ratio fell to 2.5. On changing the water three times, the ratio became successively 2.57, 2.87, and 3.0. The final product is amorphous and dried at the ordinary temperature over sulphuric acid, has the composition  $Ca_3(PO_4)_2 \cdot \frac{1}{2}H_2O$ . By continuing to boil the amorphous product first formed without changing the water, a second reaction takes place between the liquor and the precipitate, and it is observed that small crystals are produced. This change takes place very slowly if the amount of salt present be less than 1 per cent., but more quickly if the weight is between 1 and 50 per cent. The boiling was maintained for three hours in all cases, and

with weights of salt 0.5, 0.65, and 0.8 per cent., the ratios  $\text{CaO}:\text{P}_2\text{O}_5$  were respectively 2.73, 2.74, and 2.79. Microscopical examination showed that these were all mixtures of an amorphous with a crystalline substance. With the following weights of salt, 1, 1.25, 1.5, 2.0, 2.5, 3.0, 4.0, 8.5, and 50 per cent. of the weight of the water, the ratios were 2.3, 2.22, 2.22, 2.18, 2.19, 2.13, 2.1, 2.09, and 2.09. Of these, with 1 per cent. the product was a mixture, whereas with 1.25 and 1.5 per cent. the crystallisation was complete, and the product appeared to be  $\text{Ca}_3(\text{PO}_4)_2 + 4\text{Ca}_2\text{H}_2(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$ . In the more concentrated solutions the crystals consist of this substance mixed with anhydrous bicalcium salt. The authors arrive at the conclusion that the conversion of the hydrated bicalcium salt into the anhydrous bicalcium salt when heated in boiling water is due to a reaction which takes place in two stages, amorphous tricalcium phosphate being an intermediate product. The complete transformation is not always possible, and is only complete in an acid medium. The authors have never obtained a salt having exactly this composition except by precipitating a boiling solution of mono- and di-sodium phosphate with calcium chloride. Moreover, in order to obtain hydrated bicalcium phosphate it is necessary to work in an acid menstruum. The formation of this salt by the interaction of calcium chloride and disodium phosphate takes place in two stages. The first product is gelatinous tricalcium phosphate, a liquid, acid to litmus and methyl orange, which changes into crystallised bicalcium phosphate, a reaction which takes place the more quickly the more concentrated the solutions, but is never really complete unless the acidity of the menstruum be increased by the addition of phosphoric acid.—T. A. L.

*Basic Sulphate of Alumina.* W. C. Ferguson. J. Amer. Chem. Soc. 16, [3], 153—156.

MANY samples of commercial sulphate of alumina contain from a trace to 2.5 per cent. of alumina in excess of that required to form the normal sulphate. In the commercial analysis of such products it is usual to calculate the alumina necessary for the formation of the normal sulphate and return it as "combined," any alumina in excess of this being termed "free." The former is alone considered useful for sizing with resinate of alumina. This conventional view of the composition and function of sulphate of alumina containing excess of alumina appears to be irrational, as salts containing excess of base are to be expected from an oxide as feebly basic as is alumina, and, moreover, the "free" alumina may react with resinate of soda and yield resinate of alumina in the same way as the normal sulphate. Experiment confirms this view, inasmuch as even aluminate of soda in which the alumina is acting as a weak acid gives a precipitate of resinate of alumina on the addition of resinate of soda. A comparison was also made between a neutral sulphate of alumina containing 17 per cent. of alumina and a basic sulphate containing the same total percentage, including 2 per cent. of "free" alumina. When these samples were treated with an equal quantity of resinate of soda insufficient to precipitate all the alumina, and the precipitates filtered, washed with the same amount of water, and ignited, it was found that 4.40 grms. were obtained from the neutral sulphate and 6.98 grms. from the basic sulphate—a considerable advantage on the side of the latter. The author summarises the matter as follows:—Excess of alumina in commercial sulphate of alumina is not "free," but present as a basic sulphate. Such basic sulphate forms resinate of alumina more readily than does the neutral sulphate, and is on that account more economical. The method of stating analyses of sulphate of alumina should be changed so as to give its proper value to the alumina in excess of that required to form neutral sulphate.—B. B.

*Improvements in the Manufacture of Chlorine.* A. Brand, London. Eng. Pat. 11,040, June 6, 1893.

HYDROCHLORIC acid gas, obtained by dehydrating the aqueous acid by sulphuric acid, is passed through a series of interchangeable "decomposers" charged with a mixture of nitric and hydrochloric acids. The chlorine and nitrosyl chloride evolved are led through towers to be brought into contact with sulphuric acid, which becomes "nitrous vitriol," and the gas is then passed through water to withdraw hydrochloric acid. The chlorine thus obtained may be applied in the manufacture of bleaching powder or otherwise. The nitrous vitriol that accumulates is denitrated by any of the known methods. The water of the wash-tower eventually becomes aqueous hydrochloric acid, which is applied as described. The sulphuric acid used as a dehydrator is concentrated for re-use. In working the series of decomposers, when the nitric acid in the first vessel of the series is exhausted, the next vessel is made first, and so on, in order.—F. S.

*Improvements in the Treatment of the Waste from Gas-Liquor to obtain Useful Products therefrom.* H. W. Crowther, West Bromwich, Stafford. Eng. Pat. 11,964, June 17, 1893.

THE gas-liquor remaining after distillation from it of ammonia is treated with lime-kiln or other gases containing carbonic acid, the precipitated calcium carbonate is allowed to subside, and the cleared separated liquid is agitated with nearly sufficient precipitated cuprous oxide, mixed with water to a creamy consistence, to form a cuprous salt with the sulphocyanide present. The mixture is then slightly acidulated, preferably with hydrochloric acid. After agitation, subsidence, and removal of the supernatant liquor, the cuprous sulphocyanide is collected on a filter, washed, and used to obtain any desired sulphocyanide of an alkali or alkaline earth by treating it with such in the state of carbonate, oxide, or hydroxide, the latter preferably in the case of an alkali being used. The cuprous oxide reproduced is available for another operation.—E. S.

*Improvements in Evaporating Brine and other Liquors and Apparatus therefor.* F. W. Scott and F. W. Scott, jun., London, and E. G. Scott, Liverpool. Eng. Pat. 12,574, June 29, 1893.

*Improvements in the Production of Cyanides.* J. Addie and J. Cunningham, Glasgow, and W. Macfarlane, Glengarnock. Eng. Pat. 12,572, June 27, 1893.

COKE, or other carbonaceous fuel, and an alkali, as pearl-ash, are charged into a blast-furnace, lined with dolomite, or other basic or neutral lining, and the hot blast is admitted. At a certain height in the furnace a horizontal pipe admits passage for the potassic or other cyanide blown forward into a collecting box, communicating with a series of vertical condensing pipes, opening into boxes at the bottom, in which boxes the cyanide accumulates, and is collected in a dry state. It is stated that a high temperature is attained in the furnace.—E. S.

*Improvements in and connected with Tanks for Electrical Decomposition of Chloride of Sodium or Potassium in Solution.* J. C. Richardson, London. Eng. Pat. 12,857, June 30, 1893.

See under XI., page 645.

*In Apparatus for Obtaining Carbonic Acid.* A. Müller, Nürtingen, Schwablen, Germany. Eng. Pat. 13,927, July 18, 1894.

The apparatus is constructed to effect the continuous production of carbonic acid from alkaline liquids, first, by subjecting them to a preliminary heating by the expelled carbonic acid, and then by subjecting them to the direct heat of gases of combustion. The upper portion of the apparatus consists of a rectangular casing connected to the lower section by means of an outer flange, and the entire apparatus, shown in longitudinal section, is made of wrought iron, except the pipe connections and overflow pipes, which are of cast iron.

The saturated liquor from an absorbing apparatus is pumped through pipes not shown in this figure, into the cooling compartment A, so as to reach to the upper edges of the over-flow pipes *d*, whence it flows to the bottom of the tubular boiler E, from which it overflows on to the corrugated plate D, and has outlet by a pipe shown in dotted lines, to be re-introduced into the absorbing apparatus after having first circulated through a cooler. When the apparatus is fully charged with liquid, gases of combustion or of roasting are passed in through the pipe B into the space C, from which they pass through the upper series of tubes *a*, as indicated by the arrows "2" into the space C', passing out into the space C through the lower series of tubes *a*, and having exit by the discharge-pipe H to a purifying apparatus. This passage of hot gases beneath the corrugated plate D raises the liquid upon it to boiling point, and the carbonic acid which begins to be expelled at 80° C., passes through the thin vertical tubes *b* and heats the surrounding liquid, which also evolves the gas, the exit for which is through opposite pipes in the dome G.—E. S.

*Improved Method and Apparatus for Making Vinegar and Maturing Spirits.* R. H. Leaker, Bristol. Eng. Pat. 15,475, August 15, 1893.

See under XVII., page 655.

*Improvements in the Manufacture of Cement from Chance or Le Blanc Alkali Waste or the like.* B. K. Rigby, Ditton. F. A. R. Neill, St. Helens, and A. C. Carr, Rainhill. Eng. Pat. 19,705, October 19, 1893.

See under IX., page 638.

*Process of and Apparatus for Utilising Producer-Gas for Calcining Limestone.* A. J. Boulton, London. From A. F. Hatch, Chicago, U.S.A. Eng. Pat. 1991, January 30, 1894.

PRODUCER-GAS, if it can be caused to generate a sufficiently intense heat to effect "sticking" at the lower end of the column of limestone in the kiln, is a desirable form of fuel for calcining limestone.

To render producer-gas, which is inherently low in calorific power, suitable for this purpose it is introduced, according to this invention, simultaneously from opposite sides of the kiln, and at the same time air, under pressure, is admitted at points immediately above the gas-inlets. The air and gas, striking against the limestone, become thoroughly mixed and in burning produce the required high temperature.

The kiln A may be of any ordinary construction. At the desired height, where "sticking" is to be effected, are

openings B through the wall. These are divided by diaphragms *q* into gas-inlets *r* and air-inlets *p*. The diaphragms *q* stop short of the inner side of the wall, and so form mixing and combustion chambers *o*, in which the gas and air unite. It is claimed that the method of utilising producer-gas not only permits the proper "sticking" at the lower end of the limestone column to be effected, but also prevents "wall-climbing" by the products of combustion.

—R. B. P.

*A Bleaching Preparation or Mixture, applicable also for other purposes.* H. Wächter, Bielefeld, Germany. Eng. Pat. 4791, March 7, 1894.

THE bleaching preparation is obtained by boiling together stated proportions of soda, lime, zinc, tin, "or similar metals," chlorine solution, and an oil or fat, with water. "By the addition of zinc, tin, or similar metals, chlorine in solution, oil or other fats, the mixture becomes a soap-like mass and the water is eliminated, hydrogen being generated: by repeated stirring, the mixture is turned into a pulverulent mass, and may then be used for all materials without injuring them." This mixture boiled with much water is proposed as a substitute for petroleum for the preservation of boring and shaping machines. It is also stated that the mixture may be applied in purifying petroleum intended for use as a lighting or heating agent, and in purifying fibres in the manufacture of paper pulp.—E. S.

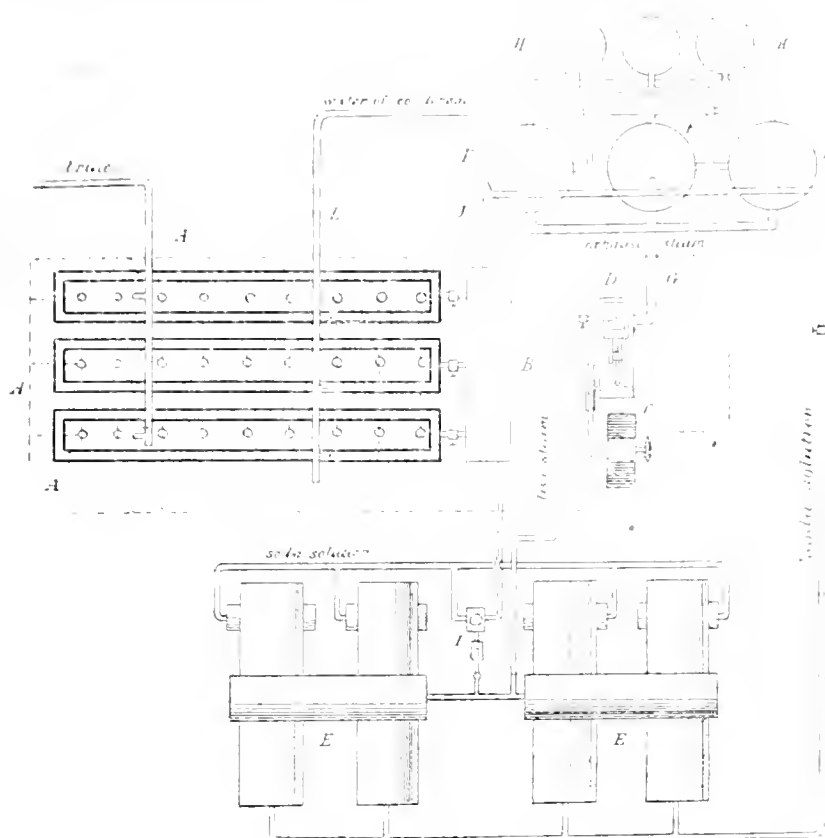

*Improvements in Producing Nitric Acid and Metals from Nitrates.* J. D. Darling and H. E. Forrest, Philadelphia, U.S.A. Eng. Pat. 5808, March 20, 1894.

See under XI., page 647.

*Improved Method and Apparatus for Manufacturing Caustic Soda.* T. Craney, Bay City, U.S.A. Eng. Pat. 6426, March 30, 1894.

CAUSTIC SODA is prepared from salt brine by electrolysis, the decomposition in the cells not being carried to its full limit, but only to the extent of producing a 1 to 2 per

cent. solution of caustic soda, which is drawn off, and its place supplied by water of condensation from the evaporators; while the salt brine on the anode side is made good to its full degree of strength.

In the above drawing, A is the series of electrolytic cells, B the receiver for the dilute caustic soda solution from the cathode cells, C the electric generators, D the steam engines, E the boilers, which are fed with weak soda solution, to be run, when about doubled in strength, into F, the evaporators or vacuum pans, from which the concentrated solution is discharged into H, the fusing kettles. G is the connections for conducting the exhaust steam from the engine to the evaporators; and L is a return pipe by which water of condensation is supplied to the cathode compartments of the cells. A feed pump, I, and a pipe, J, for carrying the surplus of the evaporating pans, are also shown. It is stated that the greatest economy is derived from a continuous operation of all the parts of the plant. No reference is made to the production of chlorine.—E. S.

#### PATENT.

*Improved Methods of treating the Vitreous Surfaces of Articles made of or from China, Earthenware, Glass, or the like Materials for hermetically joining same.*  
H. Doulton, Lambeth, and J. Slater, Burslem. Eng. Pat. 20,947, November 4, 1893.

THE vitreous surfaces of the article to which metallic connection has to be made, are coated with the preparation described in Eng. Pat. 12,939 of 1892 (this Journal, 1893, 763) consisting of one drachm of bichloride of platinum (which has been well washed to eliminate the free acid) one ounce of balsam of sulphur, and three ounces of spirit of turpentine, and fired in an enamelled kiln. "Metallising" can also be effected by the use of gold or silver oxide or platinum sponge. The coated parts can then be joined by soldering in the ordinary way. The process is found useful for joining sheets of glass, between which documents, &c. have been placed for preservation, so that both sides are visible; and also for constructing and sealing glass vessels.—B. B.

### VIII.—GLASS, POTTERY, AND ENAMELS.

*The Utilisation of Blast-Furnace Slag.* A. D. Elbers. Eng. and Mining J. 1894, 392.

See under X., page 643.

### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*The Chemical and Physical Examination of Portland Cement.* T. B. Stillman. J. Amer. Chem. Soc. 16 [3], 161—173. (This Journal, 1894, 275.)

THE paper contains illustrations of various well-known testing machines and recapitulates the usual canons of

careful cement-testing. Particular stress is laid upon the increase in tensile strength caused by the use of considerable pressure in filling the moulds, as in German practice. Thus, cement gauged in America had a tensile strength of 700 lb. per square inch at 30 days, and the same cement tested at Berlin by Bohme gave 875 lb. per square inch at 28 days. The author advocates the use of mechanical gauging to eliminate the factor of personal skill. He quotes a valuable opinion of H. le Chatelier, given in a paper presented at the last meeting of the American Institute of Mining Engineers, August 1893, which runs as follows:—"The method of tension is at present most widely used, but the preference for it is not well founded. Here, as in rupture by bending, only the *surface* of the briquette acts in a really useful way, and its inevitable irregularities and alterations so greatly affect the precision of the results that they can be in no case trusted nearer than about 20 per cent. This preponderant influence of the superficial parts was first shown by the fact that the resistance of briquettes of different sizes increases, not with the section, but, on the contrary, with the perimeter. Finally, M. Durand-Claye has shown that the interior of a briquette may be removed without notably diminishing its resistance to rupture by tension, and has given a complete theoretical explanation of the phenomenon which seemed at first sight paradoxical."

The author considers that the determination of the value of Portland cement requires the following tests:—(1) chemical analysis; (2) determination of fineness; (3) determination of tensile strength (preferably on mechanically-gauged briquettes); (4) determination of crushing strength; (5) determination of variation of volume by a test of the class of Fajja's hot test.—B. B.

*Determination of the Refractoriness of Fireclays.* H. O. Hoffman and C. D. Demond. Eng. and Min. J. 1894, 367—369.

Two methods are available for determining the refractoriness of a fireclay: (1) by deduction from the results of its analysis; (2) by direct experiment with it at high temperatures. Seger has shown that whilst the fusing point of pure alumina lies above that of his cone No. 36, and that of silica is identical with the fusing point of cone No. 35, mixtures of the two oxides are less refractory than either alone, the maximum refractoriness being found for  $Al_2O_3 \cdot 2SiO_2$  and the minimum for  $Al_2O_3 \cdot 17SiO_2$ , a decrease of fusibility occurring as the proportion of silica is further increased. For an ordinary fireclay therefore (apart from its content of oxides other than silica and alumina) the refractoriness increases with the percentage of alumina. The precise influence of foreign oxides is disputed, Bischof holding that such substances increase in fluxing effect in proportion to their molecular weights, while Seger's dictum is that ferric oxide is especially vigorous in this respect. It is agreed, however, that should the sum of these oxides exceed 6 per cent. of the ignited clay, such clay cannot be considered refractory. Regard must be paid not only to the chemical composition of a fireclay, but also to its mechanical structure, a coarse-grained clay being less fusible than a fine-grained, and a compact than a loose one, *ceteris paribus*. The authors have endeavoured to find a means of determining the refractoriness of clay without the use of extremely high temperatures, and have adopted a furnace fed by gas and air, both heated before combustion, and so constructed that the behaviour of the test-pieces could be observed. The test-pieces were pyramidal, about  $\frac{3}{4}$  in. at the base and having a height of  $2\frac{1}{2}$  in., and were made from materials ground to pass a 100-mesh sieve, mixed with water or dextrin. These were well dried, heated over a Bunsen burner, and subjected to the temperature of the furnace. In order to gauge the refractoriness of the clay, lime (added in the form of calcium carbonate) was used as a flux, being employed in regulated amount alone or in admixture with silica. Two such mixtures that proved useful are three parts of silica to one of calcium carbonate, and five of silica to one of calcium carbonate. The quantity of flux requisite to cause fusion of the test-cones serves as a measure of the refractoriness of the clay. The results are

recorded in a series of reproductions from photographs of the test-pieces, for which the original should be consulted.

—B. B.

## PATENTS.

*Improvements in the Manufacture of Cement.* G. Guj, Paris, France. Eng. Pat. 7211, April 7, 1893.

CARBONACEOUS schists, shales, or slaty substances are used as a substitute for the clay generally employed in the manufacture of cement. Such materials are mixed with limestone in proportions governed by the usual ratio of acid to basic oxides, thoroughly powdered and incorporated, damped, moulded into briquettes, and burnt in a ring kiln. The carbonaceous matter present in the schist is advantageous in that it acts as a substitute for a portion of the fuel necessary to burn the cement to the requisite degree.

*Improved Decorative Material or Surface in Imitation of Marble.* G. A. Goegg and J. C. Früh, Geneva, Switzerland. Eng. Pat. 12,468, June 26, 1893. (Under International Convention.)

DOLOMITE is calcined at such a temperature that it is rendered capable of setting with water. It is veined with pigments in a mould, the bottom of which constitutes the face of the finished slab, and on this face a backing of similar material not coloured or decorated, and mixed, if desired, with "sand, broken tiles, and the like," is cast, a composite slab having a marbled face being thus produced.

—B. B.

*Improvements in the Manufacture of Cement from Chance or Le Blanc Alkali Waste or the like.* B. K. Rigby, Ditton, F. A. R. Neill, St. Helen's, and A. C. Carr, Rainhill. Eng. Pat. 19,705, October 19, 1893.

THE waste is run into tanks, washed by decantation to remove soluble salts, and mixed with sufficient lime, "in the form of oxide, carbonate, or hydrate," to reduce the total percentage of objectionable impurities to 3 per cent. or  $3\frac{1}{2}$  per cent. of the whole, reckoned on the dry material. The deleterious constituents of Chance waste are calcium sulphate, sodium sulphate, ferrous sulphide, and free sulphur; those in ammonia-soda waste (which is particularly specified) are calcium sulphate, calcium chloride, and sodium chloride. The mixture of washed waste and lime is used for making cement in the customary manner. The washing tanks used for purifying the waste are patented.

—B. B.

*Improvements in Apparatus for Crushing Dry or Wet Materials, such as Cements, Lime, Plaster, Alabaster, Kaolin, Quartz, Phosphates, Materials, and the like.* C. Morel, Dromène, France, and A. Heimpel, Drome, France. Eng. Pat. 1377, January 22, 1894.

See under I., page 623.

*Improvements in and relating to the Production of Asphaltic Composition in the form of a Powder or of a Mastic.* C. H. Slicer, Baltimore, U.S.A. Eng. Pat. 2582, February 6, 1894.

THE merit of natural asphalt rock, such as that known as Neufchatel, depends on the fine state of division of the calcium carbonate or other mineral matter and the perfection of the coating of the constituent particles with the bituminous matter. The bituminous matter itself is found, upon extraction from the mineral matter, to be semi-fluid and plastic. The patentee imitates the natural material by taking 1 part by weight of pure asphaltum (rendering it plastic if necessary by the addition of heavy petroleum oil in the usual way), adding to it 50 per cent. of its weight of benzoline or gasoline, and mixing the product with 9 parts by weight of powdered limestone. The state of division

of the limestone is such that about 50 per cent. of it will pass through a 100-mesh sieve, the remainder passing in about equal proportions through a 60-, 40-, and 30-mesh sieve. An alternative plan consists in grinding the limestone so that the whole will pass a 60-mesh sieve. The solvent used for the asphalt is removed by exposing the mass to a temperature of  $200^{\circ}$  to  $250^{\circ}$  F., whereby the solvent is recovered and the asphalt fused, consolidating the mineral matter, each particle of which is coated with asphalt. The solvent may also be removed by evaporation by an air-blast at the ordinary temperature and the asphalt fused *in situ* when the product is being laid down as a paving material. Asphalts containing matter insoluble in benzoline need to be used in greater proportion than is specified above. The process may be used for improving the quality of natural asphalt rocks poor in bituminous matter. Another application of the method is the preparation of a mastic in the following manner. A natural asphalt rock in powder containing a known amount of asphalt is treated with pure asphalt mixed with benzoline, the solvent driven off at a temperature of  $200^{\circ}$  to  $212^{\circ}$  F., and a mastic thus formed. The proportions requisite vary with the richness of the asphalt rock in asphalt, the fineness of the mineral matter, and the quality of the asphalt added.—B. B.

*Improvements in the Manufacture of Artificial Stone and Marble.* P. Baumert and A. Pieck, Berlin, Germany. Eng. Pat. 4223, February 28, 1894.

The artificial stone or marble is made from a mixture of cheap aggregate such as sand or powdered slag and a binding material, e.g., magnesite and enough solution of sulphate of magnesia of "12° to 20°" to moisten and set the mixture. The face of the artificial stone is made in a corresponding manner, save that the aggregate is of better quality, consisting of ground marble or similar stone. The two layers are consolidated by pressure, and the whole allowed to harden.—B. B.

*Improvements in or Connected with Cements or Cement Work.* C. A. Ropes, Liverpool, and J. C. Sellars, Birkenhead. Eng. Pat. 5595, March 17, 1894.

FOUR-AND-A-HALF parts of barytes (barium sulphate or carbonate), 3 of silicate of soda, and  $4\frac{1}{2}$  of Portland or Roman cement, are used to constitute a cement which can be used for making joints or covering surfaces that are more or less exposed to contact with water. The mode of application may be varied according to the purpose in hand and the time during which it is desirable that the mixture shall remain unset. In the case of the setting being required to take place after three or four hours the barytes and silicate of soda may be applied and the Portland or Roman cement blown or dusted on. The composition may be applied to metal surfaces and is said to preserve them from rusting. Alum alone or with silicate of soda may also be applied to ordinary cement to increase the resistance of the cement to the action of water.—H. B.

## X.—METALLURGY.

*Observations on the Constitution of the Rock Matrix of Platinum.* S. Mennier. Comptes rend. 1894, 118, 368—369.

The author draws attention to the agreement of a note by Inostranzeff (Comptes rend. January 29, 1894) with an earlier publication of his own, in regard to the resemblance between the irregular and often filiform occurrence of native platinum in its matrix and that of metallic minerals in meteorites. This resemblance he attributes to identity in the conditions of formation. The platiniferous rock cannot

have been produced entirely by fusion, as the magnesium silicate rock would fuse before the platinum was even softened; whilst, if sufficiently heated, the silicates would ultimately enclose spheroidal grains of platinum, and would exhibit an entirely different fracture from that of the present rock. He holds that the metal has been deposited in fissures in the original peridotite by the interaction of hydrogen and platinum chloride vapour at a temperature far below fusing point. His own experiments point to this conclusion, and further account for the occurrence of limonite, magnetite, or chromite, by supposing them to be formed through the action of water upon iron and chromium (similarly deposited) at the time that the peridotite became changed into serpentine. These theories, while combating the idea that meteorites are necessarily formed by igneous fusion, are directly concerned with the origin of the fundamental rocks of the earth.—W. G. M.

*The Metallurgy of Lead.* J. B. Hannay. Mining Journal, 64, 428—425 and 452—453.

(A paper read before the Institute of Mining and Metallurgy.)

I. *Reactions of Lead and Sulphur.*—The author decides against the existence of subsulphides of lead, showing that they are mixtures of Pb and PbS, which can be fractionated by successive fusion and partial solidification.

II. *Specific Gravity of Lead Sulphide.*—This was found to be 7.766 for both the native and artificial varieties. It was found necessary to make the determinations in benzene, as water oxidises finely-ground galena even in the cold.

The specific gravities of fused mixtures of PbS and Pb, in proportions equivalent to Pb<sub>2</sub>S<sub>3</sub>, Pb<sub>3</sub>S<sub>2</sub>, Pb<sub>4</sub>S, Pb<sub>5</sub>S, and Pb<sub>6</sub>S, gave numbers very close to the means of the specific gravities of the constituents.

III. The method of analysis was to add in small quantities at a time, the galena, finely powdered, to a mixture of nitric acid and potassium chlorate at 50° C. After evaporating to dryness, pure sodium carbonate and a little water were added, and the mixture was boiled for a few minutes. After cooling, pure sodium bicarbonate was added and the whole allowed to digest for a quarter of an hour. It is claimed that by this treatment all the lead remains in the insoluble part, whilst the sulphur as sodium sulphate is left in solution.

IV. This division of the paper contains a series of investigations to test the truth of the reactions commonly said to underlie the theory of lead smelting.

(a.) The reaction represented by—

is first investigated. The experimental method ultimately adopted was, to add cautiously one substance in the solid state to the other, fused in an atmosphere of nitrogen, and to correct and investigate the solid and gaseous products.

It was found that the equation given did not represent the whole of the reaction, as lead sulphide appears to form a volatile series of compounds with SO<sub>2</sub>, CO<sub>2</sub>, CO, and H<sub>2</sub>O. These products are colourless gases at and above the temperature at which hard glass tubing softens, but are decomposed on cooling into PbS, and the gas combined with it. The SO<sub>2</sub> compound appears to be PbS.SO<sub>2</sub>.

Lead sulphide by itself was shown to be perfectly non-volatile at a white heat in an atmosphere of nitrogen.

Liquid SO<sub>2</sub> under pressure does not form the compound with PbS, but the reaction which appears to take place, is—  
 $4\text{PbS} + \text{SO}_2 = 2\text{PbS.PbO} + \text{S}_2$

The reaction between PbS and PbSO<sub>4</sub> varies according to the temperature and the proportions used. The extremes of the reaction appear to be—

When the heat is pushed high enough, the silica of the porcelain-crucible used begins to react, and the results are very complicated.

(b.) The author next examines the reactions between litharge and galena, and finds that the equation usually given, viz.:  $\text{PbS} + 2\text{PbO} = \text{Pb}_2\text{S} + \text{SO}_2$  does not represent the reaction. The mutual action of these substances also varies with the quantities and temperatures used. In this case the extreme reactions are—

The matter on cooling separates into two layers, the upper one being the  $(\text{Pb}_2\text{SO}_4 + 6\text{PbO}) + 4\text{PbS}$  and the lower  $(6\text{PbS} - \text{Pb}_2\text{S})$ . The other extreme of the action is—

The smelters' grey or black slags consist of the mixture on the right-hand side of equation (20) without the lead.

The compound  $\text{PbO.PbS}$  is rapidly oxidised by air to a mixture of  $\text{PbO}$  and  $\text{PbSO}_4$ ,  $\text{SO}_2$  being given off.

(c.) The action of carbon on sulphate and silicate is examined. The silicate is not reduced by carbon at any temperature, but the sulphate reacts thus—

(d.) The action of heat on lead sulphite is shown to vary with temperature, and may be caused to produce either volatile  $\text{PbS.SO}_2$  or a mixture of  $\text{PbS}$ ,  $\text{PbO}$  and  $\text{PbSO}_4$ .

V. The operations of smelting lead ores are shown by the results of these investigations to be the alternate formation of mixtures of lead and lead sulphide followed by the liquation of the more fusible lead. The explanation is found for the practice of adding lime at a certain stage, viz., to effect the decomposition of the silicate of lead; and the existence of the volatile lead compounds with  $\text{SO}_2$ , &c., is shown to account for the formation of the obnoxious lead fume.

VI. A new method of smelting lead ores is proposed, by blowing air through melted galena in a basic-lined converter. The volatile compound  $\text{PbS.SO}_2$  will be formed, and can be condensed in the form of either  $\text{PbSO}_4$  or  $\text{PbS}$ , and mixed with a subsequent charge. It is claimed that the process is capable of great variation according to the product required.—J. M.

#### Alloys of Iron and Nickel. F. Osmovl. Comptes rend. 113, 532—534.

THE author has examined a series of nickel-iron alloys (prepared by R. A. Hadfield) of the following compositions:—

Mark.	Carbon.	Si licon.	Manganese.	Nickel.
A	0.19	0.31	0.79	0.27
C	0.13	0.23	0.72	0.94
E	0.19	0.20	0.65	3.82
G	0.17	0.28	0.68	7.65
J	0.23	0.24	0.93	15.48
K	0.19	0.27	0.98	19.64
L	0.16	0.39	1.00	24.51
M	0.14	0.28	0.86	29.07
N	0.15	0.31	1.08	49.65

The three "points of transformation" noted by Teheroff as  $a_1$ ,  $a_2$ , and  $a_3$ , respectively, were found at the following temperatures:—

	$a_1$	$a_2$	$a_3$
Steel containing 0.16 per cent. of carbon, but not nickel.	600° C.	700°—750° C.	820° C.
A	635—640	695—715	765—775
C	645—625	685—645	745—755
E	550—565	635—645	
G		595—545	
J		120°—130°	
K		65°—85°	

With L the transformation was not complete at the ordinary temperature. No point of any kind was noticeable with M; with N a feebly marked point was observed at 340°—380°, apparently due to the nickel, and not to the iron.

As regards magnetic qualities, all the alloys from A to L were strongly magnetic, the property being somewhat less marked with the alloys II to L. M was almost non-magnetic, especially at 70°; whilst N showed a slight degree of magnetism, probably because the nickel was in excess. J, K, and L were markedly magnetipolar; L became non-magnetic on heating, so long as it did not cool below 50°; between 50° and 0° it became magnetic, but lost the property on again heating to redness.

The hardness of samples J, K, and L was greatly increased (as tested by a file) during cooling, as the molecular rearrangement progressed. The magnetic polarity and degree of hardness appeared to change simultaneously, both being due to incomplete transformation.—C. R. A. W.

#### Nickel: its History, Uses, and Distribution.

A. G. Charlton. J. Soc. Arts. 42, 496—511.

THE author describes the history of nickel from the earliest period, and in doing so points out that the Bactrian King Euthydenos, 250 B.C., employed coins containing 22 to 23 per cent. of nickel and 77 to 78 per cent. of copper, which closely approximates to the proportion 25 to 75, which experience has taught is the most desirable admixture of these metals for coinage. In these old coins no arsenic is shown by analysis, which debars arsenical ores as being the source of nickel, and points to the use of sulphides, since the silicates could scarcely have been treated at that time.

The commercial use of nickel received its chief impetus only as recently as 1888, when the Canadian Copper Company erected their first furnace, the advantages of the nickel-steel alloy being at about that time investigated in this country by Riley. The results of the latter are to be found in the Journal of the Iron and Steel Institute of May 1889 (this Journal, 1889, 547 and 896).

One by one the objections raised against nickel-steel have now been removed, the effect of cold weather on the plates having been proved to be of no consequence. The toughness of nickel-steel renders it particularly useful for armour-plates, and is illustrated by the fact that blocks cut from some plates at Bethlehem, many of them weighing several tons, cannot by any method yet devised be profitably broken up into sizes suitable for returning to the furnace. Surface hardened plates with the extremely hard exterior, and the tough untreated steel behind, shatter forged steel Holzer projectiles, made of highly carbonised steel containing 0.8 to 0.94 of carbon and 0.94 to 2 per cent. of chromium, which have hitherto proved irresistible. Nickel steel is practically incorrodible and can be advantageously made in the basic open hearth furnace.

Whilst a thousand tons of nickel flooded the market in the early part of the century, over ten million pounds, that is about

five times the quantity, was produced in 1891, the excess probably having been used in nickel steel. There is considerable hesitation in adopting a new material in such cases as for boiler plates, bridge building, and marine engineering, where the metal is subjected to extremes of temperature, but extensive experiments are being carried out, and last year it was decided to place sections of nickel-steel propeller shafting in two of the United States warships. Using this stronger steel will warrant boring out the shaft, materially lessening the weight, whilst preserving its efficiency, and, moreover, such cored shafting can be hollow forged when the hole is large enough to admit a mandril. If nickel-steel can be applied to the construction of boilers, it will enable their thickness to be reduced one-third. The results of some comparative trials are given in the New York Mining Journal of February 25, 1893, from which the following deductions are drawn:—(1.) Nickel steel has an elastic limit of nearly 31 per cent. more than ordinary steel. (2.) The tensile strength of nickel steel is greater by about 20 per cent. (3.) The ductility of steel is not reduced by the presence of nickel.

Another important channel of consumption is the manufacture of a nickel-copper alloy (Ni 20 per cent., Cu 80 per cent.), for casing bullets to be used with small-bore rifles. This alloy has a higher degree of tenacity than the best brass, combined with a higher coefficient of elongation.

The author then deals with the geological distribution of nickel ores. In describing the Canadian deposits he points out that, according to Browne, the ore frequently loses the character of a copper ore which it possesses at the surface, becoming more and more nickeliferous and less cupriferous as the depth increases. The evidence of this, however, would hardly appear to be sufficiently extended to justify founding any general conclusions of similar enrichments in other cases. The following analyses of the average output in the respective mines show the ratios between the nickel and copper contents of the ore:—

	Copper Cliff.	Evans.	Stobie.
Cu.....	1.31	1.43	1.92
Ni.....	5.57	3.74	2.31

The higher the nickel contents of the pyrrhotite in these ores the lower is the ratio of copper to nickel. This is scarcely chance, but results probably from the relation existing between the small contents of copper and iron held in the silicates of the respective eruptive magmas. In speaking of Garnierite he points out that the deeper brown it is the richer the ore is reported to be. This also points to the fact that the association with iron appears to favourably affect the nickel contents of the ore.

Finally the author deals with the genesis of nickel deposits and concludes that it may in most instances be traced to the ultrabasic rocks and their derivatives, serpentines, and magnesian silicates. It is believed that the nickeliferous rocks came from greater depths within the earth than circulating water is likely to have penetrated; much deeper probably than any vein fissure could have extended to. The eruption of these rocks may probably have brought them within reach of surface agencies, and the subsequent leaching by mineral waters may account for the principal deposits at the disposal of the miner existing in their present form and condition.—A. W.

#### *The Results of Heat Treatment on Manganese Steel, and their Bearing upon Carbon Steel.* R. A. Hadfield. Iron and Steel Institute, Spring Meeting, 1894.

THE author disputes the validity of the  $\beta$ -iron theory in explaining the points of recalescence and the disappearance of magnetism in iron and steel. He believes that it will be eventually found that the disappearance of magnetism in manganese steel is considerably due to a particular kind of carbide of manganese, or carbides of manganese and iron, the properties of which vary according to the thermal treatment.

Considering the large amount of iron present in these steels it might be imagined that this non-magnetisability was not permanent, and the present experiments show that this is to some extent correct. The  $\beta$ - or hard form of iron explanation is hardly possible, for it is found that the same material in each case, possessing practically the same composition, can be made to become magnetic or non-magnetic at will. The author believes that the explanation must be looked for in some other direction than allotropic modifications of iron, whether in respect to manganese steel or quenched carbon steel. The true one will probably be found by examining the various carbides of iron and manganese. Both carbon steel, if rapidly cooled, and manganese steel, when quenched in water or normally, show no recalescence or other critical points, which the author believes is strong proof of the formation of carbides, probably of a much more complex nature than hitherto imagined.

The inconsistency in the  $\beta$ -iron theory pointed out by Wigham, that the permanent magnetism of hard steel, which is supposed to consist of  $\beta$ -iron was not compatible with the non-magnetisability of manganese steel, which also is supposed to contain  $\beta$ -iron, has not been satisfactorily explained. Hardness seems to be quite independent of magnetic characteristics, as very hard carbon steels are magnetic whilst hard manganese steel is non-magnetic, although the latter can now be made to become considerably magnetic. If the presence or absence of these properties can be shown to be independent of the physical property known as hardness, it can hardly be possible to claim that non-magnetic steel is proof of the existence of a non-magnetic  $\alpha$ - or  $\gamma$ -iron. Further, if  $\beta$ -iron can be made magnetic or non-magnetic at will, and of practically the same hardness in each condition, it will be inconsistent to say that the non-magnetic state of iron heated above 740° C. is due to the existence of atoms of  $\beta$ - or hard iron retained in that form even when cooled down. Roberts-Austen recently stated that the author failed to distinguish between the hardness or softness of the atoms and the hardness or softness of the mass. Miller, when speaking of  $\beta$ -iron, says, "We are faced with the following exceedingly difficult proposition:  $\beta$ -iron is as soft as glass and brittle,  $\alpha$ -iron soft and tough. This being so, carbon is no directly hardening constituent." The author believes that advance must now come from the fuller study of micro-structure and analytical methods. He agrees with Osmond that carbon at high temperatures possesses "a particular chemical activity"; not, however, in producing  $\beta$ -iron, but in forming carbides, whose properties as yet are imperfectly understood.

The author then describes his own experiments. A piece of non-magnetic manganese steel was cemented in the ordinary manner and afterwards magnetised, when it retained a considerable coercive force. After being kept several months this coercive power was lost, showing it to have been only feeble. The effect of forging and water-quenching on this magnetic material was to render it equally as non-magnetic as in its original state. A bar of manganese steel was cemented and became magnetic. Half the bar was heated, forged, and water-quenched and became non-magnetic, the other half being left in the cemented condition, thus producing a combination of magnetic and non-magnetic qualities on the same bar. The author thinks that the change is a question of continuous heating (probably changing or decomposing the particular form of carbon or carbide) rather than an increase or decrease of carbon, such as is produced by cementation or annealing. To test this, a sample was placed for 50 hours in an annealing furnace, and was then found susceptible to magnetic influence. Apparently the heat treatment must be continuous through a considerable time and accompanied by very slow cooling. This is evidenced by the fact that merely heating manganese steel to a very high temperature for a brief period two or three times will not change its non-magnetic character.

The author then tried the effect of decarbonising manganese steel. The term is often a mis-nomer, since so-called decarbonisation of cast iron to produce malleable castings does not reduce the amount of carbon, the change of state of metal being due to a change of the carbon. Manganese seems to retard this change, and it would seem that

carbide of manganese under these conditions is not readily decomposed or dissociated. A thin bar of manganese steel was decarbonised from 1.08 to 0.06 per cent. of carbon, and was then found to possess considerable magnetic susceptibilities. Unlike the cemented samples, however, when heated, forged, and water-quenched, the decarbonised metal in no case again became non-magnetic. The magnetism was persistent, although apparently no change in the chemical composition had occurred, except as regards carbon. The suggestion thus presents itself that the magnetic qualities of manganese steel are considerably influenced by carbide of manganese. This is supported by the fact that the susceptibility of "Low" manganese steel is twice or three times that of *spiegel*, although the amount of manganese is practically the same in both cases. The conditions in which carbon exists in steel are becoming of more and more technical importance, and methods of analysis have yet to be devised to properly estimate them. A sample of cast iron containing 3.07 per cent. of graphite was, after quenching, found to contain only 1.74 per cent. of graphite and 0.83 per cent. of combined carbon, the remainder, 0.62 per cent. being unaccounted for, and consequently present in some other form not easily detected by ordinary analytical methods. No carbon could be lost by merely heating, since a fortnight's previous annealing of the same sample still left the total carbon at 3.07 per cent. The removal of carbon therefore is not necessary to produce a soft and tough casting; all that is required is the transference from the hardening to temper or graphitic temper carbon. Taking these changes of malleable cast iron and manganese steel into consideration, "does it not seem unnecessary, in order to explain the hardness produced in steel by water-quenching, to call into play a hypothetical explanation that iron is changed from the  $\alpha$ , or soft state, which all admit, into the supposititious, or  $\beta$  hard form."

A bibliography of the literature on the question is appended.—A. W.

*The Physical Influence of Elements on Iron.* J. O. Arnold. Iron and Steel Institute, Spring Meeting, 1894.

The object of this research was to gain, if possible, decisive answers to the two questions: (1) Is the influence of elements on iron governed by the periodic law as enunciated by Roberts-Austen? (2) Is there an intensely hard allotropic modification of the metal iron as stated by Osmond? The author attacks strongly the  $\beta$ -iron theory, and gives results of a large number of experiments, from which he argues that it cannot be accepted. The theory is attacked by the preparation of a series of alloys of practically pure iron with appreciable quantities (1 to 2 per cent.) of the various elements, the preparation of which was beset with numerous difficulties. A consideration of the results shows that the alloys, without exception, are harder than pure iron. Copper, the atomic volume of which is practically identical with that of iron, and which, according to the periodic law, should have little or no effect, was found to considerably harden the iron, much more so even than nickel, which is alleged to rank next to carbon in hardening power. Phosphorus also, which should theoretically have a softening influence, also appears to have a hardening effect. There is likewise a great difference in the effects upon iron of the two closely related elements, arsenic and phosphorus. Three hardened bars, supposed to contain elements more or less powerful in their  $\beta$ -iron-producing properties, all bent double without any sign of fracture. Further, when the three elements supposed to be most efficient in producing  $\alpha$ - or soft iron were tried, the bars began to break. The author allows to  $\beta$ -iron theorists that the sulphur alloy is the softest of the series, but he combats nearly every other conclusion. "The inconsiderable nature of the abrasion hardness produced in the whole of the other alloys may be exemplified by the fact that after the most drastic hardening they all filed with ease, and could be turned and drilled without difficulty (except perhaps the phosphorus alloy) with ordinary shop tools."

The author speaks of the three points of arrestation during the heating and cooling of irons by the terms Ar 1, which is the lowest temperature (650° C.), Ar 2, the intermediate temperature (750° C.), and Ar 3 the highest

(850° C.). Ar 2 was originally regarded by Osmond as probably the retarded termination of the point Ar 3. The author believes that Ar 3 marks the formation of a sub-carbide of iron, whilst the point Ar 1 is due to the combination of the elements to form the normal carbide,  $\text{Fe}_3\text{C}$ . He finds that the absorption of Ar 3 into Ar 1 is coincident with the practical disappearance of the sub-carbide. He admits that the hypothesis in respect to Ar 3 is negatived by the alleged fact that electrolytic iron also develops this point in its most marked degree, but he maintains that the evidence in support of the latter fact is very feeble. He cannot state absolutely that chemically pure iron only shows the point Ar 2, because such a metal has yet to be prepared, but there is evidence of considerable weight against the appearance of Ar 3.

A general review of the recalcrescence results in reference to irons containing about 0.1 per cent. of carbon and 1.5 per cent. of the alloying element shows:—(1) the position of Ar 1 on heating is distinctly raised by the presence of silicon, chromium, arsenic, phosphorus, sulphur, aluminium, tungsten, and manganese, and less decisively by nickel. On cooling, the point is lowered by tungsten, manganese, and nickel, and raised by silicon, arsenic, phosphorus, chromium, and slightly by aluminium and sulphur; (2) Ar 2 is the only truly reversible point, and is singularly constant in its position; (3) Ar 3 is entirely eliminated by silicon, aluminium, phosphorus, and arsenic. Tungsten much diminishes its intensity, but does not greatly affect its position. Manganese, chromium, nickel, and copper lower it to or below Ar 2, whilst the action of sulphur is dubious.

Finally, the two original items of inquiry are replied to as follows:—(1) "The experimental evidence has proved beyond doubt that the ultimate physical influence of elements on iron is not in any way governed by the periodic law." (2) "That no element except carbon has (*per se*) the power of conferring upon quenched iron the property of abrasion hardness to any extent worthy of consideration."

A written contribution to the discussion by Osmond defends the position of the latter. He says that point Ar 2 marks the appearance of magnetism and is due to an allotropic change in the iron itself. All that is changed since 1890 is that points Ar 2 and Ar 3 are seen to be definitely separated, and that instead of a single allotropic modification of iron, there are at least two; in other words iron is in the  $\alpha$  state below Ar 2, is in the  $\beta$  state between Ar 2 and Ar 3, and in the  $\gamma$  state above Ar 3. He maintains that Arnold, while combating the atomic volume theory, supports it by his own experiments, and says that it is proved (1) That hydrogen, carbon, manganese, nickel, and copper lower Ar 3; (2) That carbon, manganese, and nickel lower the double point Ar 3, 2, when they are present in sufficient quantity; and (3) That tungsten, aluminium, silica, arsenic, and phosphorus tend, as the quantity in which they are present increases, to obliterate Ar 3, without modifying its position. All these facts are in accordance with the law of atomic volume, and some of them are even borrowed from Arnold's results. The law of Roberts-Austen is a limited one. "It assumes that the foreign body preserves in solution its natural and individual state, and does not form chemical compounds with the solvent. The starting point at which these compounds cease to intervene is very variable. In alloying iron with such high proportions of these bodies as 1.50 per cent. Mr. Arnold often exceeds these limits, as is abundantly proved by his own investigations on the structure of his alloys, especially in the case of phosphorus, of arsenic, and of sulphur. He therefore seeks under these conditions a verification where one was impossible."—A. W.

*The Walrand-Legnèsel Process as applied to Steel Castings.* G. J. Snelus. Iron and Steel Institute, Spring Meeting, 1894.

The process has for its object the production of steel castings suited to a general foundry, and consists in adding at the end of the ordinary blow a definite quantity of melted ferro-silicon, then making the after-blow, turning down when the extra silicon is burnt out and adding the final ferro-manganese, aluminium, &c., as circumstances require.

The object of adding the ferro-silicon is to increase the temperature, and thus to keep the metal fluid, by the oxidation of the silicon during the after-blow. The use of more siliceous pigs to commence with, and also the addition of ferro-silicon to the metal during the ordinary blowing have both been tried for increasing the temperature, but neither have proved satisfactory, because, in the first place the heat produced by the burning of the silicon is largely carried out of the converter, and in the second, an excess of silicon used in these ways is difficult to be got rid of before all the carbon is burnt. The use of spiegeleisen, with an after-blow of two minutes to burn out the manganese, and thus increase the temperature, was tried by the author ten years ago, and the metal was certainly found to be more fluid and freer from gas cavities, but the difference was not so great as to warrant continuing the process. The advantages of silicon over manganese for this purpose are, that it generates more heat unit for unit, and the flame indication when to terminate the after-blow is better marked.

The advantages of adding the ferro-silicon for the after-blow are; (1) Ordinary Bessemer pig-iron with two or three per cent. of silicon can be used, thus ensuring a steel comparatively free from silicon; (2) The combustion of the added silicon produces such a large amount of heat at the right time, and so rapidly, that the metal becomes very fluid; (3) As the silicon burns to a solid it leaves the metal comparatively free from gas, and the steel is sound and free from gas cavities; (4) In consequence of the metal being so fluid and already free from oxide of iron, the ferro-manganese, or other substances added, such as aluminium, are more effective and remain in the final steel; and (5) that in consequence of the great fluidity of the metal much more time and facility is given for casting operations.

The author gives the results of analyses and mechanical tests of metal produced by this process and shows the cost. He also works out by heat units the result that the temperature of the bath is increased by about 240° C. in two minutes by the burning of the silicon alone in the after-blow.—A. W.

#### *The Capacity and Form of Blast Furnaces.* W. Hawdon. Iron and Steel Institute, Spring Meeting, 1894.

AFTER dealing with the functions of the various parts of the blast furnace, the author proceeds to point out the advantage of an upper bosh, which can sustain the weight of a large portion of the materials above it, thus leaving that immediately below more loose and open, by which means the escape of the gases is rendered more easy and the working of the furnace freer. It is said that such a furnace has the benefit of the free working of a low furnace, combined with the efficiency of a high one. The author then proceeds to give figures obtained by him with a furnace constructed on these lines, by which it is shown that the output is increased, the fuel consumed materially decreased, although the weight of ironstone is slightly increased, and the grade of iron produced is much higher, showing the very regular working obtained. The improvement is not claimed as entirely due to the upper bosh, but to the combined effect of a somewhat large well, the low bosh, and the narrowing of the part above the bosh.—A. W.

#### *The Utilisation of Blast Furnace Slag.* A. D. Elbers. Eng. and Mining J. 1894, 392—393.

THE author traverses the dictum that blast furnace slag is useless for manurial purposes, on the ground that only the acid slags are unattacked by weathering, and that slags which are fairly basic decompose readily in the soil yielding silica and lime as plant food, and—it is said—serving to fix ammonia and nitric acid reaching the soil by means of rain. Another use for slag, which is of permanent importance, is the manufacture of slag wool for which a growing demand exists. The presence of sulphur in blast furnace slag is a hindrance to this and other applications, e.g., the preparation of slag cement, and the elimination of

the sulphur is therefore a point to be aimed at. The refining of blast furnace slag by converting it into slag wool and thus removing a good deal of ferruginous matter, has been attempted for the production of a ceramic raw material, but the process is at present in the experimental stage. The composition of refined slag corresponds approximately with the formula  $12Ca(Mg)O \cdot 4Al_2O_3 \cdot 7SiO_2$ . Its melting point is nearly as high as that of orthoclase, but is lowered by the addition of quartz. The comparatively low content of alumina of refined slag, causes the ceramic mixtures made by its aid to be more nearly transparent than those of the usual constituents. In consequence of their properties the value of refined slag in the ceramic industry arises from the fact that vitrification can be effected at a moderate temperature, and with a low proportion of vitrifying ingredients, e.g., felspar, and that the product is noticeably translucent. The author states that porcelain clays are often less plastic than is desirable, and it is consequently difficult to add to them sufficient vitrifying material to yield a good ware without making the previous work of moulding and modelling unduly difficult, so that a substance like refined slag, capable of acting as a vitrifying constituent without being used in excessive amount, and thus detracting from the plasticity of the raw pottery, is of especial value. Another suggested use for refined slag is in the manufacture of glass, as a substitute for a portion of the silica and lime.—B. B.

### PATENTS.

*Improvements in the Production of Chlorine and Refined Lead, and in the Recovery of the Silver the Lead contains.* F. M. Lyte, London. Eng. Pat. 7264, April 8, 1893.

LEAD chloride is formed from yellow lead oxide (preferably) or from lead oxychloride, by grinding with an excess of aqueous hydrochloric acid, in a pan having a granite bottom and stoneware sides; or enamelled metal pans may be used, an example of which is shown, in which stone mullers are carried round by cross-arms and stay-ropes of a frame revolving on a centre, and resting at their outer ends on rollers on a circular rail supported by adjusting screws to regulate the grinding action. Silver chloride may be dissolved out of the product by strong hydrochloric acid or solution of a suitable alkaline earthy chloride; and on filtering the warmed solution through spongy lead, silver is deposited. Or the argentiferous lead chloride may be fused over lead, the chlorides being used in successive charges until the lead is sufficiently enriched for recovery of the silver by cupellation.

Crude lead may be oxidised in a basic-lined Bessemer converter, in which a high temperature is attained, and the silver becomes concentrated in the small proportion of lead that escapes oxidation. The last traces of silver may then be recovered from the litharge and fume in the manner first described.

Lead chloride may be purified by solution in hot water and crystallisation, the same water or mother-liquor being repeatedly used. The chloride is then washed, dried, fused, and electrolytically decomposed in the fused state, to obtain lead and chlorine, in the apparatus represented above.

The iron pan A set over the furnace M, contains lead, L, into which the earthenware or plumbago bell B dips, the lead being melted to receive it, and then allowed to set, while the bell is charged with lead chloride by removing the cover B', and afterwards with successive additions through the inlet F. E E are carbon anodes, each hollowed to receive a fusible metal core, preferably of lead, connected to the conducting wires. H is the cathode terminal dipping into the lead L. As the molten lead increases by decomposition of the chloride, it runs off by the pipe D. The

apparatus shown is intended for connection in series, the chlorine entering from another cell by the pipe G and having outlet by the pipe G'. It is a feature of the invention, that the air in the cell should be displaced by a non-oxidising gas, as chlorine or nitrogen, in order to avoid any formation of lead oxide in the process.—E. S.

*An Improved Process, and Furnaces used therewith, for Copper Smelting and Refining.* A. O. Vicenna. Vallenar, Chili. S. America. Eng. Pat. 7667, April 14, 1893.

In this process, by means of an improved compound furnace, sulphurous copper ores may be reduced to copper bars in one heat by a single and continuous operation. The first part of the furnace consists of a cupola furnace supplied with the usual blast or tyvere pipes. Into this furnace the softer and more easily reduced ore is placed together with coke or other fuel. It is rapidly smelted and then discharged into an auxiliary reverberatory hearth. Here the dust ores and siliceous ores are added and the iron is slagged. But little additional heat is here required, and this is supplied by auxiliary furnaces. The slag is removed in the usual way, and the molten copper sulphide, settling at the bottom, passes on into secondary hearths. Here the matte free from slag is exposed alternately to a desulphurising and oxidising current of air, heated by special pipes sunk into the sides of the hearth.

Before the matte gets cool and begins to redden, it may be reheated by opening dampers, and any remaining iron and impurities removed by the addition of a siliceous ore to form a slag. The bath in these secondary chambers may be thus alternatively reheated and treated with siliceous ores, or oxidised by the admission of air for desulphurisation until the copper, in a single heat, from its first smelting is reduced to fine bars. If desired, the ordinary poling with green timber may be carried out in the secondary hearths. The auxiliary hearths and grates may also be used with an ordinary reverberatory furnace in place of the cupola, though in this case the copper pyrites ore must be previously calcined. It is stated that poor ores, which previously could not be treated at a profit, may be smelted in this combined furnace to advantage.—A. W.

*An Improved Process for the Preparation of Iron or Steel Plates for Nickel or other Plating.* C. T. J. Oppermann, London. Eng. Pat. 7791, April 17, 1893.

By this process iron or steel plates are prepared for a polished plating of nickel or other metal, without rendering them too brittle to be afterwards worked and bent into any desired shape. Ordinary steel or iron plates (known as tin plates) are given an extra coating of soft metal, such as tin, an alloy of tin and aluminium, or an alloy of tin and lead, thus protecting them so that the succeeding rolling does not unduly harden the iron or steel. This extra coating is obtained by dipping in a bath of the soft metal in a molten state, after which the plates are rolled between polished rollers and polished by a revolving mop charged with crocus or tripoli powder.

The plates are then cleaned by means of a mixture of lime and water, rinsed with cold water, and suspended in the electro bath of nickel, &c. The electro-plated articles are dried in sawdust and polished by the revolving mop, which is this time charged with dry lime.—A. W.

*An Improved Method of Recovering Tin from Tin Plates, Tin Boxes, and other Tin Waste.* C. W. Kriens and J. R. Harper, both of London. Eng. Pat. 9257, May 9, 1893.

In this process the tin plates or boxes are placed in a solution of caustic soda of sp. gr. 1.200, containing about 15 per cent. of soda, which is contained in iron tanks. The tin is all removed in about 48 hours if cold; in from four to six hours if the solution is boiled. When saturated with tin, the solution is evaporated to dryness, and roasted or calcined, while charcoal is added in sufficient quantity to

carbonise the whole mass. From the residue the alkaline salts are washed out, reacidified with milk of lime, and used for a fresh operation. The tin is recovered as an insoluble oxide or carbonate. The sheet iron is not affected and can be further utilised.—A. W.

*Improvements in and relating to Pickling Iron and Steel Plates and other Articles previous to Tinning or Galvanising.* H. J. Kirkman, Swansea. Eng. Pat. 10,463, May 27, 1893.

In pickling iron or steel plates and other articles with sulphuric acid as preparative to galvanising, a stated proportion of sodium chloride or other equivalent chloride, or of hydrochloric acid, is added in order to hasten the pickling process. The pickling liquid may be used until there is no longer sufficient sulphuric acid present to decompose the chloride formed in the process.—E. S.

*An Improved Metallic Alloy.* D. W. Sugg, London. Eng. Pat. 10,608, May 30, 1893.

Fifty parts of copper, 40 parts of zinc, and aluminium in the proportion of two and a half per cent. of the whole are taken. This is one example, but others may be obtained by varying the amounts of copper and zinc to the same proportion of aluminium.

The mode of preparation of the alloy varies:—For a hard metal, the copper and aluminium are first mixed to form a copper alloy and the zinc added in small pieces during continuous agitation of the molten mass. This gives a reddish alloy that takes a high polish. For a ductile metal the zinc and aluminium are first mixed and the copper then added. This gives an alloy resembling brass. In both cases the metal is claimed to be non-oxidisable, proof against sea water, and, to a large extent, against acids.—A. W.

*Improvements in Steel Founding.* J. G. McRoberts, St. Louis, U.S.A. Eng. Pat. 2617, July 8, 1893. (Under international Convention.)

In steel founding about twice as much heat is required as in iron founding and in consequence shrinkage strains have to be provided for. This excessive heat also compels the employment of dry sand moulds, which are objectionable for many reasons. They are more expensive than green sand moulds. They do not yield as the steel contracts, thus giving rise to checking and cracking, especially with structures with projecting shoulders, U-shaped cross-sections, &c., and, hence, many useful forms cannot be made in cast steel.

In carrying out this process the advantages of dry sand and green sand moulds are combined. The molten metal is introduced into the moulds through a gate of substantially dry sand, but the mould itself is constructed of green sand, which becomes skin dried by the heat given off by the advancing metal before the metal actually comes into contact with the surface of the mould. Wherever cores are required, or where the molten current enters the mould and impinges as a stream upon it, dry sand is employed to prevent abrasion. Wherever resistance is offered to the shrinkage of the metal in cooling, likely to cause a rupture in the casting, the mould is of green sand, which is yielding. By this means the metal is introduced into the mould in such a manner as to prevent the formation of scars, the carrying along of foreign matter caused by the abrasion of the gate, and the casting itself is free to contract on cooling.

A further characteristic is introducing the metal into and through the mould, so that it shall not abrade any opposing part of the mould walls, by pouring it down through a gate of dry sand into a well from which it passes into the mould itself, either horizontally, or substantially horizontally, and upward. The green sand walls of the mould become skin-dried in advance of the progress of the metal, and being vented freely the moisture and gases generated in the mould are enabled to escape without interfering with the metal or the casting.

Instead of using sand any other suitable materials may be substituted, that is, refractory material, which will not abrade when molten metal is passed over it and which will not lead to the generation of steam, for making the gate, and any material of the yielding nature described for the mould itself. Steel castings made in these wet sand moulds are superior to those made in dry sand, and there is the further advantage that they may be allowed to remain in the mould for several hours, thus producing a much tougher casting than is possible with dry sand moulds, where the casting must be shaken out right away. Also checking and rupturing of the casting on shrinking are avoided, so that "reinforcements" on the casting are no longer necessary and the expense attendant on their removal is obviated.

—A. W.

*Improvements in Baths for Toughening, Strengthening, and Hardening Iron and Steel.* F. G. Bates, Philadelphia, U.S.A. Eng. Pat. 1244, January 19, 1894.

The patent refers to improved liquid baths for treating low grade steel or malleable iron for the purpose of increasing fineness of grain of the metal, improving its tensile strength, toughness, ductility, &c., or when desired rendering it harder. The bath consists of a brine of both alum, and common salt, to which brine is added oil, benzene, or other liquids, calculated to liberate hydrocarbon gas at high temperatures, and also certain salts as occasion may arise. Thus for strengthening and toughening the metal, salts of aluminium, potassium and sodium and lime are used. The hydrocarbons raise the percentage of carbon. Phosphate of lead and arsenic increase the hardness. Ammonium salts are employed to liberate ammonia gas.

The articles to be treated are heated to bright redness, placed in the bath, and allowed to remain until gas ceases to be evolved or until they are cold. Examples of the proportions in which the above salts are used are given.

—A. W.

*A New or Improved Solder for Soldering Aluminium, Aluminium Alloys, and other Metals.* O. Nicolai, Wiesbaden, Germany. Eng. Pat. 4980, March 9, 1894.

This process consists in the use of a solder for soldering aluminium of a compound of cadmium with one of the halogens, the chloride or iodide giving favourable results. The solder is conveyed on to the part to be soldered by a brush moistened with spirits of wine and the soldering pipe is then used.—A. W.

*Process for Soldering Aluminium.* E. Singer, F. Donat, and P. Kirchheim, all of Chemnitz, Saxony. Eng. Pat. 5530, March 16, 1894.

The process for soft soldering aluminium consists in dipping the parts to be soldered into a mixture of Russian tallow and Provence oil. After treating with this mixture they are joined together by means of the soldering iron with ordinary plumber's soft-solder or preferably with perfectly pure English tin. It is claimed that the parts thus soldered can be bent as well as hammered without separating, and without the solder flaking off.—A. W.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*The Use of Electrolysis in Technical Chemical Processes.* J. W. Langley. J. Amer. Chem. Soc. 16, 49—56.

THE electrical smelting of aluminium in the United States is carried on only by the Pittsburgh Reduction Co., and there under the Hall patents (This Journal, 1891, 432, and 1892, 124). The statistics regarding the installation differ in some respects from those quoted in this Journal (*loc.*

cit.): the current density is 7,000 ampères, and the yield of aluminium 1 lb. for 18.1 EHP hours. This is equivalent to a current of 1,926 ampères at 7 volts (the voltage required when the process is in full operation) acting for one hour; hence theoretically the deposit of aluminium should be 1.43 instead of 1 lb.; the reduction efficiency of the process is therefore 70 cent. The alumina dissolves to the extent of 25 per cent. in the fused cryolite, apparently without heat evolution or effervescence, forming a colourless solution, and during the electrolysis no appreciable loss of fluorine or fluoride occurs. That the alumina alone is decomposed, is explained by the low voltage required to electrolyse it, which may be calculated by dividing the number of heat units evolved in the formation of 1 gm. (not one molecule) by Thompson's number (22,900) representing the calorific equivalent of the volt: for NaF this is  $109,700 \div 22,900 = 4.8$ ; for  $Al_2F_6$  it is  $50,000 \div (6 \times 22,900) = 4.0$ ; and for  $Al_2O_3$  only  $388,929 \div (6 \times 22,900) = 2.8$ .

The *Moebius Process* for refining gold and silver is now carried out as follows by the Pennsylvania Lead Company of Pittsburgh: a current of 180 ampères and 1½ volt is passed through dilute nitric, free from sulphuric and hydrochloric acids, contained in a tank divided up into 70 compartments arranged in electrical series, each compartment measuring 18" x 24" x 17" deep and having three anodes and four cathodes 10" x 20" x 1½". The silver anodes contain 1 per cent. of impurities consisting of copper, lead, bismuth, and a little gold, and are suspended in bags; the cathodes are thin plates of fine silver.

In each compartment the average consumption of nitric acid (36 B.) is 2 lbs., and the average yield of silver (inclusive of stoppages) is 470 oz. per 24 hours. This is equivalent to nearly 1 ton per diem in the whole series or to 84 per cent. of the theoretical yield with uninterrupted current. The silver is practically 1,000 fine; but care must be taken to prevent the co-deposition of copper; there is no practical difficulty, however, in this respect.

Edson, in the *Electrical Engineer* describes the complete disinfection of the sewage from the village of Brewsters by running into the sewers sea water which had flowed in a gentle stream between 7 electrodes, viz., 4 carbon cathodes 12" x 12" x 1" and 3 platinum-coated copper anodes, through which a current of 700 ampères and 5 volts was passing. The sea-water thus treated equalled in strength a 1 per cent. solution of chloride of lime, the ratio of the cost per gallon of the two disinfectant liquids being 1:140 in favour of the electrolytic process.—W. G. M.

## PATENTS.

*Improvements in the Extraction of Chromium by Electrolysis, applicable also to the Production of Chromium Alloys.* E. Placet and J. Bonnet, Paris, France. Eng. Pat. 6751, March 30, 1893.

THESE improvements on Eng. Pat. 22,855, 1891 (this Journal, 1893, 18) relate to methods of obtaining chromium and alloys of chromium by electrolysis from the "watery" and fused electrolytes. For the first, they take 10 to 15 grains of bisulphate of potash, 100 grains of chrome alum, and 100 grains of water; heat the mixture until the salts are dissolved, and then electrolyse, when the chromium is said to deposit immediately. The strength of the bath is maintained by means of chrome alum alone, or by means of a concentrated solution of chrome alum and alkaline bisulphate, an overflow pipe being provided. Chlorate of potash and boric acid, benzoic acid, or other analogous salt, is sometimes added to assist the deposit of the metal. For the fused electrolyte, the bisulphate and chrome alum are heated together, and, instead of the potash salt, sulphate or bisulphate of soda or ammonia may be employed as a flux, or the phosphates, borates, chlorates, silicates, chlorides, fluorides, &c., alkalis or alkaline earths, or a mixture of the same; and in place of chrome alum, oxide of chromium or other salts of chromium, which will easily fuse on contact with alkaline earths. With the electrodes may be incorporated chromium compounds previously fluxed with

different fluxes and reducing agents, and, instead of carbon, different metals may be employed as electrodes to obtain alloys, and reducing gases and vapours may be admitted to the crucible by a blast-pipe or through hollow electrodes.

—J. C. R.

*Improvements in Secondary Batteries or Accumulators.* A. E. Peyrusson, Limoges, France. Eng. Pat. 11,122, April 1, 1893.

THE positive electrode is constructed of thin laminae soldered to a central core, from which—in the illustration, where the core is vertical—they radiate, being each, in addition, soldered to end discs threaded on the core. Insulating discs of larger diameter form the two ends, and serve to keep the electrode from the surrounding cylindrical negative electrode. Or thin discs threaded on the central core and soldered to it may take the place of the radial laminae.

The negative electrode is of thin vertically corrugated material, rolled several times round with the layers in contact to form a cylinder. The several layers are united by soldering to stout end-rings; and the whole is slit longitudinally at intervals to allow free circulation of the electrolyte.—E. T.

*Improvements in the Production of Chlorine and Refined Lead, and in the Recovery of the Silver the Lead contains.* F. M. Lyte, London. Eng. Pat. 7264, April 8, 1893.

See under X., page 644.

*Improvements in Electrical Accumulators or Secondary Batteries.* P. Sekoop, Zürich, Switzerland. Eng. Pat. 7,711, April 11, 1893.

THIS patent is for methods of causing the electrolyte to circulate through the cell. In one case the electrodes—which are all made to fit tightly at their sides to the containing vessel by suitable means—alternately reach to the bottom of the cell, and terminate some distance above the bottom. By a suitable pump the electrolyte is caused to enter at one end, and zigzags under and over the alternate plates to the other end.

A cell is also described, consisting of horizontally-placed perforated steel plates, which act as cathode, while insulated rods of copper or copper amalgam pass loosely through the perforations and form the anode. The electrolyte in this case enters at the bottom by a centrally-placed tube, and is withdrawn at the top of one side.—E. T.

*Improvements in and connected with Tanks for Electrical Decomposition of Chloride of Sodium or Potassium in Solution.* J. C. Richardson, London. Eng. Pat. 12,837, June 30, 1893.

THIS invention relates to electrical decomposing apparatus wherein there is no diaphragm between the electrodes to prevent re-combination of the products of decomposition, disturbance at the cathode by hydrogen being prevented chemically. But, as in the case of decomposing common salt solution to obtain chlorine gas and soda solution, the former product may set up some disturbance in escaping from the solution, or struggling to get to the surface from the lower portions of the anodes, it is proposed to arrange horizontally between the electrodes a screen of strips of slate or glass, or other uninfluenced material, which may overlap each other, like the slats of a Venetian blind, with spaces between them for the passage of the current. An arrangement of this description is shown, and another, in which the screen takes the shape of V-troughs placed below the anodes, which will prevent solution and downward pressure of gas towards the soda solution at the bottom, and also catch particles of the material of which the anodes are composed, should any become detached during the progress of the electrolysis.—J. C. R.

*Improvements in and Relating to Electric Furnaces.* H. H. Lake, London. From A. C. Girard and E. A. G. Street, Paris. Eng. Pat. 13,340, July 8, 1893.

See under H., page 626.

*An Improved Manufacture of Carbon for Electrical Purposes.* H. H. Lake, London. From A. C. Girard and E. A. G. Street, Paris, France. Eng. Pat. 13,339, July 8, 1893.

EXPERIMENTS made some time ago by Despretz and Berthelot with the object of studying facts relating to the sublimation and fusion of carbon demonstrated that, at high temperatures, carbon of different kinds passes into the graphitic state. The present invention relates to its industrial application for the manufacture of graphitic carbon on a commercial scale, and the application of such carbon to electrical purposes, notably for lighting, electrolysis, and batteries. Carbons manufactured in the ordinary manner are subjected to such a temperature as will soften, weld, fuse, or sublime the same, and they are thus transformed (either completely or in part) into graphitic carbon or graphite. The necessary heat is obtained by making the carbon part of an electric circuit with suitable moving connections as in treating rods or plates, or the requisite temperature may be arrived at by an arc playing over the surface of plates giving them a certain depth of graphite; or granular or powdered carbon may be similarly treated by passing between electrodes at a rate of flow allowing it to be brought up to the requisite temperature, and such graphitic carbon may be used in the manufacture of carbon by agglomeration or in telephones or microphones. Crude carbon may be treated, first distilling the volatile products contained therein. Eng. Pat. 13,340, 1893, is referred to as describing suitable apparatus in which to heat the carbon by an electric arc (see previous abstract).—J. C. R.

*Improvements in Electrodes and Cells for Secondary Batteries or Accumulators.* E. H. Wheeler, East Molesey. Eng. Pat. 22,912, November 29, 1893.

EACH electrode is composed of two perforated plates united at the edge to form one compound one, the perforations being conical with the bases inwards, so that the active material retained in the space between the plates, and in the perforations themselves, cannot fall out. The containing vessels are formed with grooves not reaching to the bottom. On the shoulders thus produced ledges formed on the plates rest, and thus support the latter away from the bottom of the cell.—E. T.

*Improvements in Galvanic Batteries.* A. J. Boulton, London. From C. Cudell, I. Cudell, and M. Cudell, Aix-la-Chapelle, Germany. Eng. Pat. 3749, February 21, 1894.

THE one electrode is in the shape of a cylindrical vessel of carbon or "brownstone," and is furnished with a glass or stoneware ring at its upper end. The other electrode is of perforated zinc and is attached to a cover. This cover has lugs, which, travelling in inclined grooves in the stoneware ring, enable the cell, with the help of rubber, to be sealed, while allowing gas to force its way out if the pressure rise sufficiently inside the cell.—E. T.

*Improvements in Electrodes for Arc Lamps.* E. O. Clark, New York, U.S.A. Eng. Pat. 4114, February 27, 1894.

THIS invention relates to electrodes for arc lamps provided with protective coverings to prolong the life of the electrodes and prevent useless dissipation of the electrodes or their coatings. The carbon electrodes are coated as usual with a film or covering of copper, and over this a coating of a metal differing in nature from copper, such as zinc and nickel, applied mechanically, chemically, or by electro-deposition, for which in practice excellent results are claimed, in the shape of longer life, not flaking away, dissipated, nor come to a sharp point in burning, but uniformly consumed.—J. C. R.

*Improvements in producing Nitric Acid and Metals from Nitrates.* J. D. Darling and H. C. Forrest, Philadelphia, U.S.A. Eng. Pat. 5808, March 20, 1894.

THE invention consists in electrolysis fused sodium nitrate or potassium nitrate to obtain nitric acid and metallic sodium or potassium. A double cell, preferably of aluminium, is employed, having a removable, insulated cover, to which is fixed centrally a cylinder with funnel mouth, long enough to dip into the fused salt and fitting into the top of the partition wall which divides the two cells. This wall has one or more openings to admit communication between the cells. As the nitrate is consumed, a fresh supply is introduced to the cylinder in such manner as not to admit air. The cover carries also two electrodes (one for each cell) of carbon or platinum, the vessel itself being connected to the negative pole of the source of electricity. Each electrode is surrounded (except at the bottom) by a cup, inverted, having many openings inclined upwardly towards the inside; and is carried by a clamp secured to the cover, and having a transverse and vertical passage leading through its upper part. The cups are insulated from the cover and clamps, to which they are secured.

To conduct the process, sodium nitrate, for instance, is fused in the vessel, the cover carrying the electrodes, &c., is adjusted, and the cover and vessel are connected to the opposite poles of a generator of electricity. The nitrogen peroxide and oxygen eliminated pass from the inverted cups to a series of Woulff's bottles, in which nitric acid is formed. The sodium first liberated reduces the neighbouring nitrate to nitrite and oxide, which latter dissolves in the sodium nitrite; then, both are decomposed, and the sodium set free floats on the surface of the fused salt, and may be withdrawn through an aperture closed by a plug in the side of the vessel.—E. S.

## PATENTS.

*Improvements in or Relating to the Treatment of Oils for Refining, Bleaching, and Boiling the Same.* W. N. Hartley, Dublin, and W. E. B. Blenkinsop, Wandsworth Common. Eng. Pat. 9315, May 9, 1893.

RAW linsed oil is claimed to be refined, bleached, and boiled to any desired degree of drying power, density, or viscosity at one operation. This oil should be previously cleared from

muilage and insoluble matters, either by storage in tanks, or by filtration or treatment in a centrifugal machine, or by any other convenient method; preferably mechanically at a temperature not exceeding 50° F., although slightly higher temperatures may be employed successfully. The oil is heated to 190–250° F., and air or oxygen blown through until all moisture is expelled, so that a sample remains clear and bright after cooling. A manganese salt of a fatty acid easily soluble in the oil is then added, either as a solid or in solution; preferably a strong solution of manganese linoleate is employed, the solvent being turpentine, a fatty acid, or oil, such as will form a liquid which will readily mix with the oil to be treated. About one volume of solution containing one-fourth its weight of manganese linoleate is added to 400 of oil, either during blowing, or during a temporary discontinuance of blowing, the current of air or oxygen being resumed immediately, so as to prevent the separation of insoluble matters, and about 15,000 cubic feet of air, or a corresponding quantity of oxygen, being blown through per hour per ton of oil. About an hour or less suffices to bleach the oil when at a temperature of 190° F.; the temperature may then be allowed to fall to 170° F., and more manganese linoleate solution added, say 1 to 1½ volumes per 100 of oil, the blowing being then continued until the desired viscosity is obtained. Or the oil, freed from moisture as described, may be cooled to 170° F., and treated with the full quantity of manganese linoleate at once, air being blown through until the required amount of bleaching and viscosity are attained; about 1½ hour's blowing generally suffices, it is said, to obtain a good pale boiled oil when operating with 5 tons of raw oil, the exact time being variable, according as the air current is greater or less than 15,000 cubic feet per ton per hour, according to the proportion of manganese salt used, and so on. If the oil originally used is not free from muilage, &c. it must be filtered after blowing to render it bright. The appliances used in carrying out the process are those described in the previous patent, No. 11,629 of 1890: one vessel being therein stated to refine, bleach, and boil oil at one operation, yielding a pale boiled oil of uniform quality and free from the disadvantages attending the presence of lead, always contained in oil boiled by means of lead compounds.—C. R. A. W.

*Apparatus for Extracting Substances by Volatile Solvents.* J. Meikle, Glasgow. Eng. Pat. 10,701, May 31, 1893.

See under L., page 622.

*Soap Cakes and Bars.* H. Rimmer, Sandside, Ulverston. Eng. Pat. 5225, March 13, 1894.

Soap tablets and bars are stamped in suitable dies so as to give a corrugated surface to one or more faces; the object of this is to enable the small remaining portions of similar used tablets to be completely used up by pressing them into the interstices of the corrugations so as to fill them up, and thus economise these remaining fragments. Instead of corrugations, variously formed projections or recesses may be stamped, or designs or letters may be employed with the same object.—C. R. A. W.

*Improvements in Apparatus for Extracting Fat and Glue.* F. J. Michalski, Brooklyn, New York, U.S.A. Eng. Pat. 5821, March 20, 1894.

THE process is designed for the continuous extraction of fat and glue from bones or other substances by heating them under pressure with a volatile solvent which is subsequently distilled off. The plant itself may be briefly described, in principle, as resembling a composite Soxhlet's extractor on a large scale.—A. G. B.

### XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

#### (A).—PAINTS, PIGMENTS.

*Spontaneous Combustion of a Lamp Shade.* A. Dupré. Times, May 21, 1894.

See under Analyt. and Scient. Notes, page 670.

#### PATENTS.

*Improvements in the Manufacture of Paint.* W. H. Hyatt, Stockwell, Surrey. Eng. Pat. 9194, May 8, 1893.

THE addition of one-half to one per cent. of borax or other borate to lead sulphate ground in oil, is claimed to enhance the value of the latter as a pigment, rivalling white lead both in drying and covering power.—F. H. L.

*An Improved Paint or Paint-like Composition.* W. C. Nangle, London. Eng. Pat. 11,727, June 14, 1893.

GAS-TAR, cow-dung, oak-bark, sulphur, rosia, mica, and "euphorbium" are all boiled up together, ground and thinned down. The resulting mixture is claimed to be "heat resisting, anti-corrosive, and anti-fouling," as a paint or composition.—F. H. L.

*Improvements in the Manufacture of Lead Pigments.* H. R. Gregory, Wandsworth. Eng. Pat. 13,558, July 12, 1893.

LEAD sulphate—the volatilised variety by preference—is boiled with about 10 per cent. of caustic soda until the liquid is no longer alkaline to test paper, and the resulting mixture washed and dried. As an oil pigment, it is claimed to have the body and opacity of Dutch white lead.—F. H. L.

*Improvements in Compositions or Paints for Preserving Ships' Bottoms and other Structures.* J. W. and S. J. Blake, Gosport. Eng. Pat. 1301, January 20, 1894.

THIS composition contains *inter alia* barytes, quassia, mercuric chloride, and arsenic; copper sulphate being added when it is to be used on wood.—F. H. L.

*An Improved Preparation of Colouring Matters for Dyeing, Painting, Drawing, and other Purposes.* E. Nienstaedt, L. Goldmark, and C. Herrmann, New York, U.S.A. Eng. Pat. 5078, March 10, 1894.

STICKS of wood, glass, or metal, about the size of ordinary matches, are dipped in a strong solution of any dye thickened with dextrin, &c., so as to become coated therewith. They are dried, and for use are simply immersed in the desired solvent. In the case of insoluble colours, the sticks are coated as before, and in use are rubbed down in the water in the usual manner.—F. H. L.

#### (B).—VARNISHES, &c.

##### PATENT.

*A New Material for Making Varnish, Cement, Waterproofing Material, and the like.* J. Renison, Glasgow. Eng. Pat. 9930, May 18, 1893.

THIS consists of the substance known as "Albane," which is produced by the spontaneous or artificial oxidation of gutta-percha, dissolved in a suitable solvent.—F. H. L.

## (C).—INDIA-RUBBER, &amp;c.

## PATENT.

*Improvements in Treating or Preparing Gutta-Percha and Rubber for Various Purposes.* R. Hutchinson, Cowlaire. Eng. Pat. 12,266, June 22, 1893.

This is a simplification of the process described in Eng. Pat. 17,739, 1892 (this Journal, 1893, 936), the inventor having found that by boiling together the gutta-percha or rubber with wool-grease and carbonated or caustic alkali, the former is able to remove the "lanichol" (lanolin) from the grease, and that therefore it is unnecessary to extract the lanolin in a separate operation as previously carried out.—F. H. L.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*Extraction of Tanning Materials.* Schroeder and A. Bartel. Dingler's Polyt. J. 1894, 291, 259—263.

The authors have already shown (Dingler's Polyt. J. 239, 1893) that by the use of an appropriate quantity of water

neatly all the tannin in a tan-stuff can be extracted by a few hours' digestion, and that a prolonged treatment extracts little more tannin, but deteriorates the quality of the extract by rendering soluble much of the not tannin which would otherwise remain unattacked. The method adopted was to extract the finely divided tan-stuff with 1 litre of boiling water for two hours in an extraction apparatus and to follow this by a second and third extraction with 1 litre of boiling water, each extending over 18 hours.

In the new series of experiments here recounted an amount of water relatively greater than that previously used, and three periods of two hours each, were employed. Each extraction was made with 1 litre of water, but the weight of tan-stuff extracted was diminished, in the case of quebracho from 20 to 10 grms., in the case of oakwood from 30 to 25 grms., and in the case of valonia from 10 to 7 grms.; 10 grms. respectively of myrabolans and sumach, and 20 grms. respectively of oak bark and pine bark were used as before.

The following table shows the results obtained; the rows numbered I. indicate the composition of the bark as determined by the extract made in the first two hours with the first litre of water; the rows IIa. show the composition of the extract made in the second two hours with the second litre of water, the rows IIIa. giving the same values for the third extraction; the rows IIb. and IIIb. show the composition of the bark as determined by the total extraction made by 2 litres in four hours and 3 litres in six hours respectively:—

IIIa. ....	..	0.37	0.02	0.01	..	..	..
IIIb. ....	13.00	8.95	2.01	0.31	75.73	11.27	22.5

A comparison of these results with those obtained in the previous experiments, shows that it is the duration of the extraction process which is responsible for the high proportion of not-tannins found in those experiments; thus, if the quantity of not-tannins in the first two hours' extraction be termed 100, the proportion of not-tannins found at the end of 6 hours' and of 98 hours' extraction becomes:—

	Six Hours.	Ninety-eight Hours.
Oak-bark.....	109	243
Pine-bark .....	112	228
Valonia .....	102	206
Myrabolans .....	101	136
Sumach .....	102	165
Quebracho .....	103	268
Oak-wood .....	105	420

It will also be noted that the quantity of water used has little influence on the proportion of not-tannins extracted.

Prolonged digestion does not appreciably increase the percentage of tannin extracted, so that it may be generally stated that the most profitable method of making extracts is to digest the tan-stuff with a sufficient quantity of water for a short period.

The extraction of a tanning material for analysis is, in the author's experience, best effected by allowing the weighed quantity of powdered material to soak in water in the extraction flask for half a day, and then to complete the leaching with one litre of boiling water in two hours. The size of the flask is a detail to be considered; it should be within the limits of 100—200 cc. capacity when 7—20 grms. of tan-stuff are to be extracted. Although the extraction of the tannin is not complete when the above directions are followed, yet what is more important is secured, namely, constancy of results. In practice it matters but little whether the percentages returned are too high or too low, provided they are constant among themselves.—A. G. B.

*Canaigre as a Substitute for Barks in Tanning.* United States Consular Reports, 1894, 44, 679.

Dry canaigre-root (this Journal, 1892, 622) contains from 20—40 per cent. of tannin according to age, the two-year-old roots containing more than the one-year-old. The fresh root contains about 66 per cent. of water. 112 lb. of the dry roots yield 45 lb. of extract containing 66 per cent. of tannin; the residue is said to be equal in value to wheat-

straw as cattle-food. The following analyses are by Schroeder:—

	I.	II.
Water.....	11.00	14.69
Tannin.....	34.91	27.72
Not tannins.....	18.14	9.40
Extract ash .....	1.97	2.13
Insoluble matter.....	33.98	46.06
	100.00	100.00

Canaigre-tanned leather is soft, bright, and orange-coloured, and is recommended for uppers, saddlery, and fancy leather. There is a good demand for canaigre, which may soon replace gambier.—A. G. B.

#### *The Origin of the Acid Fermentation in Tanning Liquors.*

F. H. Haeflein. Dingler's Polyt. J. 1894, 291, 186—190 and 209—214.

THESE investigations were made with an extract of pine-bark (20 grms. of bark per litre). It was found that the production of acid in such an extract is due to the growth of an organised ferment, which was cultivated and isolated. The fermentation follows the usual course, gradually waxing and waning. A detailed account of the experiments conducted for determining what constituent of the bark is converted into the acid, the nature of the gases evolved, and the influence of temperature and light, is given. The following conclusions are drawn:—

(1.) The formation of acid in a pine-bark liquor is due to a fermentation.

(2.) The ferment is a bacterium, which may be termed *bacillus corticalis*; it is not identical with the *bacillus lacti*, although it ferments milk-sugar and glucose, with the production of a soluble acid and of the same gases which it evolves from pine-bark liquor.

The microscopical appearance of the bacillus is shown in the figure (amplification not stated).

(3.) The constituents of the bark which are fermented are the saccharine substances (Fehling reducing compounds). The fermentation does not occur in pure tannin solution.

(4.) The products of the fermentation are a soluble acid and a mixture of much hydrogen and little carbon dioxide. In one experiment the evolved gas contained 94.6 per cent. of hydrogen and 5.4 per cent. of carbon dioxide; no estimation of the carbon dioxide remaining in solution is quoted.

(5.) The fermentation will not take place below 6° C.; the most favourable temperature is between 30° and 40° C.

(6.) Light hastens the fermentation.

A similar fermentation was observed in extracts of oak-bark, mimosa, and sumach, but not in extracts of quebracho and myrabolans.—A. G. B.

*Spray-tanning.* P. F. Reinsch. Dingler's Polyt. J. 1894, 292, 21—23.

Of the many attempts which have been made to improve the tanning process, having for their object a more rapid output and a more complete utilisation of the tanning material, none has proceeded on any plan other than that of immersing the hide in the tanning liquor.

"Spray-tanning" (*Bieselgerlung*) consists in causing the tanning liquor to flow down each side of the vertically suspended hide, stretched by its own weight; the liquor is received in a tank and pumped back into the reservoir from which it flows.

The plant necessary for the process consists of a number of frames, from which the hides are suspended by hooks, a reservoir supplying pipes which carry equidistant jets, so arranged that the liquor may flow on to each side of the hide, and a tank to receive the partly-spent liquor. To secure equable tanning the liquor must be constant in rate of flow and in strength; the first desideratum is secured by keeping a constant level in the reservoir, the second by adding strong liquor to maintain the specific gravity of that pumped back into the reservoir at the same figure.

The duration of the tanning is alleged to be reduced by this process, for heavy leather, to one-eighth or even one-tenth of the time expended in the usual layer process, and it is claimed that the product is equal in quality to that turned out by the old method.

It will be observed that in spray-tanning both hide and liquor are exposed to the air. Whilst this is of no moment when the process is used for mineral tannage, it is not permissible when tannin itself is used, for the tannin speedily suffers oxidation and is lost so far as the tanner is concerned. This difficulty is by no means insurmountable, inasmuch as the maintenance of an atmosphere of carbon dioxide around the hides is not difficult; all that is required is a box which shall be airtight at the bottom and sides, with a pipe for admission of the gas into the lower part; according to the author the gas will remain unmixed with air for weeks, even if the box be not covered.

A noteworthy economy effected by spray-tanning is that handling and plunging are not necessary; another is the complete utilisation of the tannin, which is most effectively extracted from each drop of liquor as it trickles over the hide. It is also in favour of the new process that it requires a smaller ground space and a less expensive installation than are required for pit-tanning. If a comparison of the two processes be made on the basis of the space necessary for laying away 600 hides, it will be found that the space for pit-tanning will be  $\frac{1000}{37}$  times that necessary for spray-tanning, or  $\frac{1000}{9}$  times if the latter process be conducted in two tiers. The cost of 28 pits is given as 4,480 marks, that of an equivalent spray apparatus as 2,000 to 3,000 marks.

Spray-tanning was specially devised for the author's ferric oxychloride and salt method of tanning; the following figures are claimed to be representative:—

Time occupied in tanning by

	Tanning in Pits.	Ferric Oxychloride in Pits.	Ferric Oxychloride in Sprays.
	Days.	Days.	Days.
Light leather .....	50	11	7
Heavy leather .....	140	28	24

#### COST OF TANNING MATERIAL FOR 1 KILO. OF RAW HIDE.

	Pfennige.
Bark .....	107
Chromium compounds .....	15
Ferric oxychloride and salt .....	5

#### LABOUR BILL FOR 100 KILOS. OF RAW HIDE.

	Marks.
Bark tannage .....	21—10
Chromotannage .....	20
Ferric oxychloride spray-tannage .....	8

Iron-tanned heavy leather is asserted to compare favourably with the best bark-tanned heavy leather. The grain is particularly durable, and the resistance to water is considerably greater than that of bark-tanned leather. For belts the iron-tanned leather is more valuable than bark-tanned, as it does not deteriorate so rapidly when exposed to dry or moist heat.—A. G. B.

#### PATENTS.

*Improvements in the Treatment of Loom pickers, Leather, and other similar Articles with Fatty Matters, and Apparatus for Effecting the same.* R. T. Gillibrand, Darwen, Lancaster. Eng. Pat. 11,248, June 8, 1893.

The various articles named in the title are enclosed in a vessel, which is then made vacuum; the oil or fat is allowed to flow in and pressure is applied.—A. G. B.

*Improvements in Tanning.* C. Heinzerling, Frankfurt-on-Main, Germany. Eng. Pat. 12,849, June 30, 1893.

The following chromium compounds are applicable in this process:—Chromic chromate,  $\text{Cr}_2(\text{CrO}_4)_3$ , prepared by dissolving chromic hydroxide (1 mol.) in chromic acid (3 mols.); "bichromate monosulphate of chromium,"  $\text{Cr}_2(\text{CrO}_4)_2\text{SO}_4$ , made by dissolving chromic hydroxide (1 mol.) in chromic acid (2 mols.) and sulphuric acid (1 mol.); "basic chromate sulphate of chromium,"  $\text{Cr}_2\text{CrO}_4\text{SO}_4$ , made like the preceding, but in the proportion of 1 mol. : 1 mol. : 1 mol.; "chromate disulphate of chromium,"  $\text{Cr}_2\text{CrO}_4(\text{SO}_4)_2$ , formed by dissolving chromic oxide (1 mol.) in sulphuric acid (2 mols.) and chromic acid (1 mol.); aluminium chromate, made by dissolving aluminium hydroxide in chromic acid; chromic thiosulphate, from the decomposition of chromium salts by thiosulphates; chromic sulphite, made either by decomposing chromium salts with neutral or acid sulphites, or by saturating a solution of sulphurous acid with chromic hydroxide; chromous chloride and chromous sulphate, made by reduction of the corresponding chromic salts with zinc dust or iron filings; chromium thiocyanate, formed by decomposing barium thiocyanate with chromic sulphate.

The following are also used:—Ferrous, aluminium, zinc and manganese thiosulphate, formed by decomposing barium thiosulphate with the sulphates of these metals; ferrous, zinc, manganese, and sodium hydrosulphite (hyposulphite), formed by the action of the metal on sulphurous acid or sodium bisulphite.

The hides, prepared as usual, are first laid in a dilute solution ( $\frac{1}{2}$  per cent.) of the above-mentioned compounds of chromic acid and chromic oxide, and then the solution is successively strengthened (up to 10–12 per cent. or even 15–20 per cent. for heavy leather). The duration of the process may vary from 8–14 days for uppers to 5–6 weeks for sole-leather. Uppers are washed after the tanning, but sole-leather should be dried without washing. Soft, pliable upper leather is advantageously tanned first in compounds of chromic acid and chromic oxide, and then in a solution of chromium thiosulphate or sulphite, for which the thiosulphate or hydrosulphites mentioned above may be substituted. When the last-named salts are used the metals contained in them are deposited as oxides in the fibre of the hide, and thus both a tanning and a colouring effect may be produced. Eleven claims cover the above points.—A. G. B.

*Improvements in Apparatus for Extracting Fat and Glue.* E. J. Machalski, Brooklyn, New York, U.S.A. Eng. Pat. 5821, March 20, 1894.

See under XII., page .

## XV.—MANURES, Etc.

*Influence of Potassium Salts on Nitrification.* J. Dumont and J. Crochetelle. Comptes rend. 117, 604–606.

In a previous communication (Comptes rend. 117, 670) the authors showed the favourable effect exercised by various potassic manures on nitrification in cleared lands rich in humus and lime. They have now continued their experiments on soils rich in humus and silicates, but poor in lime. Here, too, the addition of amounts of potassium carbonate up to 4.5 per cent. increased the rate and amount of nitrification, but, on the other hand, potassium sulphate had little or no influence. The following table gives the results found:—

NITRIC ACID FORMED IN 20 DAYS IN 1,000 GRMS. OF HEATH SOIL.

K <sub>2</sub> CO <sub>3</sub> added.	Milligrams of Nitric Acid.	K <sub>2</sub> SO <sub>4</sub> added.	Milligrams of Nitric Acid.
Per Cent.		Per Cent.	
0	24	0	25
0.1	47	0.5	54
0.2	65	1.0	19
1.0	94	1.5	24
1.5	156	2.0	19
2.0	188	2.5	20
2.5	238	3.0	27
3.0	313	3.5	25
3.5	282	4.0	20
4.0	384	4.5	20
4.5	438	5.0	18
5.0	467	..	..
6.0	375	..	..

If, when potassium sulphate is used, chalk is also added, the results are completely changed, nitrification being much increased. Thus, with 2.5 grms. of chalk added, 0.5 per cent. of potassium sulphate increased the nitrification (which, without any manure, was 25 mgrms.) to 75 mgrms., 2 per cent. to 129 mgrms., and 4 per cent. to 163 mgrms.

There can be little doubt that the effect of the potassium sulphate in the presence of calcium carbonate, either natural or added, is due to the formation of potassium carbonate by double decomposition, and not to the direct action of the sulphate.

The authors' results show that in the cultivation of soils rich in humus, nitrification is much assisted by potassium carbonate (in the form of non-lixiviated ashes, for instance) or of potassium sulphate, but that where the latter substance is used, chalk must be added if the soil is poor therein. The quantities of manurial material desirable are, of course, much smaller than the maximum proportions employed by the authors.—L. T. T.

*Influence of Iron on the Vegetation of Barley.* P. Petit. Comptes rend. 117, 1105–1107.

BARLEY was grown in sand (boiled with hydrochloric acid till all iron was dissolved out), part being watered with ferrous sulphate solution and part with ferric sulphate solution, potassium nitrate, calcium sulphate, and potassium phosphate being also supplied. The ferric sulphate was found to act as a poison; but the ferrous sulphate had no such effect, being absorbed to such an extent that the ashes of the stems and leaves contained 10 times as much iron as was present in plants grown similarly, but not treated at all with ferruginous substances; a slight increment in nitrogen was also produced. Apparently, therefore, the general opinion is incorrect that ferrous salts lose their noxious qualities in soils when they become peroxidised.

—C. R. A. W.

*The Utilisation of Blast-Furnace Slag.* A. D. Elbers. Eng. and Mining J. 1894, 392.

See under X., page 643.

## PATENTS.

*Improvements in Apparatus for Separating, Classifying, and Purifying Minerals and other Materials.* A. F. Beyer and A. G. Beyer. Paris. Eng. Pat. 3678, February 20, 1894.

See under I., page 623.

*A Liquid for Use as a Fertiliser and Insecticide, and for other Agricultural and Horticultural Purposes, applicable also as a Deodoriser and Disinfectant.* S. Elliott, Newbury, Berks. Eng. Pat. 8910, April 7, 1894.

THE soluble and solid constituents of the smoke from coal or wood are retained by water in the manner already described (this Journal, 1890, 273). The liquid so obtained is available for the purposes mentioned above. Instead of using the smoke from ordinary furnaces, a special fire may be employed to produce smoke and gases from properly selected materials.—N. H. J. M.

## XVI.—SUGAR, STARCH, GUM, Etc.

*The so-called "Turkish Honey."* A. Fajano. Chem. Zeit. 1893, 17, 1826.

"TURKISH honey" is an important article of commerce in Austria. It has a white colour, in a fresh state is dry, hard, and brittle, but deliquesces on standing. It has a pleasant taste, but leaves behind it a bitter and slightly burnt flavour, which is attributable to alum.

Its analysis gave the following result:—Water, 7.97 per cent.; invert sugar, 56.78; cane sugar, 31.02; ash, 0.31; insoluble in 80 per cent. alcohol, 3.92, which was composed of gummy matter, 68.09 per cent.; alum, 27.80; calcium sulphate, 4.08.

It is prepared by partially inverting cane sugar with acid at 80°–90° C., neutralising the product, and adding a decoction of the root of *Saponaria officinalis*. The mixture is heated for some time, with constant stirring, when a slight caramelisation takes place. Natural honey is then added and the product cooled. The addition of the decoction of *Saponaria* alters the consistency of the finished preparation.—J. G. W.

*Advantages of Heating Diffusion Juice with the Steam arising from another Diffusion.* M. Melichar. Zeit. Zuckind. Bohm. 1894, 18, 301–306.

The author calculates that as a direct source of heat 51.4 kilos. of steam are required per 100 kilos. of beet-roots, from the diffusion to the boiling process; whereas, when steam arising from the liquor is utilised, 45 kilos. of steam are needed. This saving of 6.4 kilos. of steam per 100 kilos. of roots is reduced to 5 kilos. in actual practice. The author therefore considers that the gain is not sufficient to warrant the use of the process, when the losses due to decomposition of the sugar and to the reduction in value of the products due to their increased darkness, are taken into account.—A. R. L.

*Note on the Solution of Indian Gums by Means of Hydrogen Peroxide.* H. Koechlin. Bull. Soc. Ind. Mulhouse, 1894, 36–37.

By heating together 250 grms. of crushed Indian gum, 1,000 cc. of water, and 50 cc. of hydrogen peroxide (12 vol.) for two hours to 80° C., a solution is obtained, which, however, turns wool yellow on steaming. This would appear to be due to a loss of oxygen, and can be corrected by adding bisulphite to the gum solution. Woollen fabrics are turned yellow on steaming in consequence of the oxidation of the sulphite compound, and this is more noticeable in Mather and Platt's large continuous steamer than in ordinary vats, owing to the quantity of air present in the apparatus. It can, however, be remedied by passing through sodium bisulphite. The author remarks that insoluble gums contain a product soluble in water, which is more oxygenated than the rest, and he proceeds to point out an analogy which exists between gums and several vegetable products containing simultaneously two or more substances having different amounts of oxygen. Of these he mentions madder, which contains alizarin and purpurin, logwood and Brazil-wood contain hematin and an insoluble resin, cinchona yields quinine and cinchonine, and nuxvomica and opium also contain different products. In cochineal, according to Schützenberger, there are two substances containing different quantities of oxygen, one gives a carmine on alumina and the other a ponceau on tin. The author also mentions as one of his analogies that blood contains white and red corpuscles. The note concludes with a recipe for a thickening from linseed prepared by boiling for one hour and then filtering 500 grms. of linseed, 1,000 cc. of water, 250 grms. of acetic acid, and 8–10 cc. of hydrogen peroxide (12 vols.). The quantity of hydrogen peroxide depends upon the linseed, and it is important to determine the exact quantity, as an excess causes a complete solution. The seed, after having been treated as described, is dried and the oil extracted in the usual manner.—T. A. L.

*Determination of the Crystallisable Sugar in the Beet.* H. Pellet. J. Amer. Chem. Soc. 16 [4], 266.

See under I., page 624.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Occurrence of Raffinose in Wheat Germ.* F. Schulze and S. Frankfurt. Ber. 27, 1894, 64–65.

The precipitate obtained by adding strontium hydroxide to the alcoholic extract of wheat germ, in the manner described (this Journal, 1894, 533), is decomposed with carbonic anhydride and the filtrate evaporated to a syrup, the latter being treated with successive small portions of boiling alcohol to remove the saccharose. The residual syrup is dissolved in water and absolute alcohol added to the concentrated aqueous solution, when raffinose is precipitated; it is purified by repeating the last-described operation several times. Richardson and Crumpton (Ber. 19, 1180) conjectured the presence of raffinose in wheat germ, but did not succeed in separating the sugar.—A. R. L.

*The Manufacture of Prepared Cereals.* J. Barrington White. Trans. Inst. of Brewing, 7 [2], 143–156.

The author is strongly of opinion that the prepared form of raw (unmalted) grain is the only one that can be satisfactorily employed by the brewer. The use of untreated grain in the brewery involves the erection of costly plant ("converters"), in which the preliminary gelatinisation of the "grits" is effected. Serious stoppages in the working may, and do, arise owing to a breakdown of the raking machinery, clogging of the pipes and valves, &c., due to the stiffness of the mash. The author states that 50 per cent. of prepared grain may be employed without difficulty in point of drainage, &c. Of the various forms of prepared grain the author prefers the "golden-flaked malt" manufactured from yellow European maize, since it gives "greater palate, fullness, brilliancy, and stability" than either flaked rice or white American maize (this Journal, 1894, 410). The average composition of golden-flaked maize is as follows:—Starch, 83.67; cellulose, 1.64; fat, 0.89; albuminoids, 8.27; ash, 0.45; moisture, 4.37 per cent.; and extract, 109.21 lb. per qr. of 336 lb. Of the total albuminoids, only a small amount is soluble in water.

Subsequently the author describes the manner of manipulating flaked grain in practice, and considers its influence on the composition of the wort. As regards the latter point the changes involved consist essentially in an increase in the percentage of dextrin and malto-dextrin, and a reduction in the amount of soluble albuminoids (as compared with all malt wort). To these facts the author attributes the increased fullness, conditioning power, and stability obtained by the use of flaked malt.

The frequent instability of pale all-malt beers, arising from the enforced use of pale malt—often under-reared and unsound—may be avoided by employing a darker, better-cured malt in conjunction with flaked grain, which yields a practically colourless extract.

In conclusion the author enters into some details concerning the extra profit obtainable by the use of prepared grain, and states that the material may be successfully employed in the brewing of every class of beer.

In discussion it was pointed out that the flavour and aroma of barley-malt were essentially due to the process of kilning to which it was subjected, and that in this respect flaked malt stood on the same level, since it was submitted to a similar torrefying process. At the least, flaked malt must be superior to any form of untreated grain. In regard to extract, the author said that failure to obtain full yield was quite contrary to his general experience; but that in the case of grits, the large percentage of water (13–14 per cent.) they contained would explain deficiency. A question as to the suitability of the grains for cattle-feeding was answered in the affirmative.—H. T. P.

*The Capacity of Yeast to Live in Media containing Hydrofluoric Acid.* E. Sarel. Comptes rend. 113 (1894), 253–255.

The author's experiments lead him to the following conclusions:—A yeast which has become injured to a medium

rich in hydrofluoric acid, yields, when cultivated in a medium containing less hydrofluoric acid, the more active cells, according as the original culture-medium contained more hydrofluoric acid. A yeast having become once inoculated to a certain quantity of hydrofluoric acid, retains this property. The author has obtained yeast which withstood finally 1 gram of hydrogen fluoride per litre, or six times as much as at the commencement.—A. R. L.

*Contribution to the Study of Yeasts.* P. Hautefeuille and A. Perrey. Comptes rend. 118, 589—591.

THE authors have studied the yeasts occurring during the fermentation of the various wines of Nuits and Beaune. These yeasts, with few exceptions, may be classed in three groups—(1) apiculate yeasts, occurring at the beginning of fermentation and often carrying on the fermentation to the end; (2) ellipsoidal yeasts, which appear after the fermentation has progressed for some time, are very active and rapidly (*i.e.*, in about 48 hours) entirely replace those of group 1; (3) ellipsoidal yeasts, occurring in neutral or but slightly acid must, which resemble surface yeasts in behaviour and vary in colour from rose to dark wine-red. The yeasts of this last class appear very active, but except in one instance were always accompanied by those of class 1 or 2. They are noticeable by the presence, in the vitreous protoplasma, of a spherical and highly refractive globule, which, small at first, rapidly increases and is still plainly visible in the old and granular cells. If the fresh cell is placed on a piece of moist chalk this globule increases in size till it nearly fills the cell, becomes covered with a membrane (often coloured), and the protoplasma gradually becomes differentiated into numerous minute spores, which are eventually set free by the rupture of the membrane. In nutritive material multiplication of these yeast cells generally takes place by budding, but in one case the authors observed reproduction by budding and by spores taking place side by side.—L. T. T.

*On the "Cassage" of Wine.* A. Bonffard. Comptes rend. 1894, 118, 827—829.

THE author has investigated the cause of this malady, which exhibited itself among wines from the vintage of 1893, displaying the following symptoms:—On exposure to the air the previously clear wine became covered with a thin, iridescent film of colouring matter which gradually increased in amount and finally fell to the bottom as a reddish-brown precipitate, leaving the wine considerably lighter in colour and of a yellowish hue.

Pasteurisation and the addition of sulphurous acid are effectual means of preventing this malady, pasteurisation effecting even the re-solution of the precipitate and improving the colour of a wine which was already affected.

The preventative action of pasteurisation would point to the disease being the result of bacterial action, but its action upon a wine already affected would indicate that the action was a chemical one upon the colouring matter of the wine. This latter is supported by the facts that filtration through a Chamberland filter, and treatment with sulphurous acid or mercuric chloride do not prevent the disease.

Sulphurous acid added to the extent of 0.03 gram per litre prevents "cassage" but its action is explained by its avidity for oxygen.

The author is of opinion that the prevalence of this disease among wines of the 1893 vintage is due to the precocious maturity of the grapes produced by the extreme meteorological conditions which obtained then, whereby the colouring matter of the grape was rendered particularly liable to precipitation.—J. G. W.

*The Chemical Action of Abrastol (Calcium Naphthol Sulphonate) on Wine.* Scheurer-Kestner. Comptes rend. 1894, 118, 74—76.

ABRASTOL (or asaprol), the calcium salt of  $\beta$ -naphthol sulphonic acid (this Journal, 1894, 534 and 548), is being employed as a preservative in the manufacture of wine, and

is replacing "plastering." The absence of any unfavourable physiological action and the small quantity requisite for the purpose are greatly in its favour. It has, however, been asserted that abrastol in the presence of the principal constituent of wine, gives rise to the production of free sulphuric acid. This statement the author, from experiments made with cream of tartar and with wine, proves to be erroneous, the products of the interaction of cream of tartar and calcium naphthol sulphonate being calcium tartrate, potassium naphthol sulphonate, and naphthol sulphate.—J. G. W.

*The Flavour of Whisky, as Influenced by the Materials used and by the Processes of Manufacture.* J. A. Nettleton. Trans. Inst. Brewing, 7, 167—195.

FOR the purposes of this paper the author classifies whiskies into (1) pot-still whiskies and (2) patent-still whiskies.

*Patent-still Whiskies.*—In patent-still whiskies only very minute quantities of flavouring constituents are present. The higher alcohols amount to only one-fourth to one-fifth, the compound ethers to about one-half to one-third of the average quantities present in pot-still whiskies. Furfural is absent and the amount of free acid is scarcely appreciable. Of the higher alcohols present, the larger portion is propyl alcohol, the one most closely resembling ordinary alcohol. In the patent stills the separation of the constituents of the wort is so complete that in one distillation the spirit leaves the lowest spirit plate almost constantly at a strength of 67.68 over proof, or containing about 93 per cent. of absolute alcohol. The spirits obtained with patent stills are very pure, being, for instance, well below the Swiss or Ruse's standard, which fixes 0.12 on the proof gallon as the maximum percentage of secondary constituents allowable, but they are comparatively flavourless. Large quantities of patent-still spirit are used for blending, and in many patent-still distilleries German yeast is the main product. The flavouring or secondary constituents are, however, present in the original wort, and during distillation collect in large quantities in the various "feints" vessels. The author suggests that with care and judgment, some of these flavouring constituents could with advantage be diverted into the spirit receiver, and a superior flavoured whisky be thus obtained.

*Pot-still Whiskies.*—These whiskies embrace (a) all-malt whiskies, usually styled Scotch, and (b) malt and grain whiskies, usually styled Irish, though some of the Irish whiskies are all-malt whiskies. The Scotch whiskies may further be subdivided into (1) Highland, (2) Lowland, and (3) intermediate whiskies. The wort of Highland whiskies is prepared very similarly to a brewer's wort, but at a lower initial and final temperature, and attenuates from a gravity of 1,050 down to that of water. There are two main distillations, namely, of the wash into "low wines," followed by the collection of "fine spirit." The collected spirit has an average strength of 15 per cent. over proof. The malt for Lowland whisky is usually a mixture of foreign and home-grown barley, dried at a moderate or even low heat. If peat is used it is only sparingly, the malt having little of the peaty flavour. The wort is made as in the Highlands, but the attenuation is more rapid, being effected in 48 hours. There are three main distillations—the wash into low wines; these into weak and strong feints; and the strong feints into spirits and feints. The spirits are collected at from 40° to 60° over proof. In the "intermediate" whiskies (amongst which some of the finest may be classed), pure water and superior, well-cured malt entirely free from peaty flavours are used. A mixture of double and treble distilling is often employed. In the Irish whiskies the waters used vary greatly, some being stream or soft, others well or hard water. The mashing material consists of a mixture of moderately dried malt and a large quantity of kilned grain—barley and oats. Lower initial heats are used in mashing; the wort collected ranges in gravity from 1,040 to 1,050 and is attenuated down to 1,000. The stills are heated by furnaces, and there are three main distillations, the spirit being collected at 45° to 50° over proof.

In Irish distilleries where raw grain is used kilning is often dispensed with if the grain is dry enough for grinding.

Thorough kilning has, however, undoubtedly beneficial effects. It diminishes mould, ensures a sounder wort, and one less susceptible to bacterial fermentation, and therefore tends to reduce the amount of secondary products. Highly-dried malts are found to give worts which, after attenuation, are less acid and from which the first distillate is distinctly purer. Even with maize in patent still distilleries kilning is advantageous.

Where raw grain is used this might be advantageously mashed at 170°–180°, the mash temperature lowered to 140°, and the fine malt then added.

The main principles governing the quantity and quality of the flavourings are: the quality of the extract present in the wort, the type or species of yeast used, the temperatures employed throughout the process, and the duration of fermentation. The finer shades of flavour possessed by the original mashing materials are distinctly discernible in the extract, and though they blend during fermentation with other flavours not previously existent, they yet impart a distinct character to the product. The various species of yeast each tend to create certain and peculiar flavouring bodies. High fermentation temperatures produce rapid and exhaustive attenuation, but are also responsible for the powerful bacterial fermentation which accompanies the main process, and which contributes more than anything else to the production both of desirable and undesirable flavours. Prolongation of the time of fermentation at high temperatures causes a rapid increase of acidity at the expense of the alcohols, and a simultaneous production of several distinctive flavours.

The patent or Coffey still eliminates alike good and bad flavours. Pot-stills only partially eliminate the secondary products, this elimination varying greatly in degree at different distilleries. There is still amongst distillers a preference for furnace-heated stills. The method of heating governs the flavour of the distillate in several ways. In steam-heated stills no new flavours are likely to be created, and greater control is possible over rate of distillation and separation of fractions. The furnaces are more likely to cook the wash and partly burn the sedimentary matter. The presence of furfural in pot-still whisky is attributed to this action, together with the high drying of the malt. The higher percentage of this alcohol in Scotch than in Irish whiskies is due to the higher kiln-drying and the double instead of treble rectification. The author believes that fine flavours may be obtained by employing a furnace for the wash-stills, but steam-jackets or coils for the low wines and feints still.

The esters, to which undoubtedly the special flavour and aroma are largely due, are chiefly found in the low wines, feints, and foreshots. Of the low boiling esters, ethylic, propylic, and isopropylic acetates have been recognised in whiskies. There is some evidence that in all-malt whisky there is an excess of esters over the quantities found in malt and grain whiskey. In the collection of the distillates cloth-filtering is advisable. The cloth filters are found to be covered with a mineral and oily deposit, and the oils so retained are the heaviest and probably least desirable of the esters present.

The processes taking place during maturation of spirit are still far from fully known. Bell's analyses, whilst showing a reduction of furfural, seem against the generally received theory of the oxidation of the higher alcohols, as he found severely any reduction of these in the fully-matured spirit. Allen's analyses, on the other hand, tend to show a consistent reduction of the higher alcohols during ageing.

In the discussion on the paper Dr. Sykes pointed out that in choosing the mashing temperature the distiller had to keep in view the preservation intact of the diastase in the mash; distillers, with very few exceptions, depended on brewers for their yeast. Both Bell and Allen in their analyses used modifications of Berthelot's method for estimating the esters, but Allen first removed the furfural. He believed the furfural present in spirits was derived from the gum in the mash. Lintner, jun., has shown that a gum is present in malt and barley, which on hydrolysis splits up into galactose and xylose. This latter, if distilled with

hydrochloric acid, yields about half its weight of furfural, and the small amount of acid in the mash probably acts to a limited extent in the same way. —L. T. P.

## PATENTS.

*Improved Method and Apparatus for Collecting the Carbonic Acid generated during the Fermentation of Beer or Wine.* K. Michel and M. Frank, Munich, Germany. Eng. Pat. 10,263, May 24, 1893.

FERMENTATION is effected in a tun of cylindrical or other form provided with an air-tight cover which is fitted with a pressure-gauge, the necessary taps, valves, &c., and a man-hole. In practice, in order that the quality of the beer may be unimpaired, the man-hole is left open for the first 2–3 days after pitching and the wort aerated at intervals in the usual way. When fermentation is in full swing, the man-hole is closed and the carbonic acid drawn off automatically under a pressure of one atmosphere or more. When the evolution of gas begins to sensibly slacken, the fermenting vessel is again opened and the beer finished in the usual way. The carbonic acid thus obtained is stated to require no purification before being compressed or otherwise utilised. —H. T. P.

*An Improved Method of and Means for Utilising Spent Hops for Food and Litter.* E. O. Greening, Lee; and E. W. Greening, Thames Ditton. Eng. Pat. 10,941, June 5, 1893.

THE inventors chief claim is the utilisation of spent hops as a food or litter.

Hop waste, obtained from breweries, is first dried by storing the hops in stacks, constructed with hollow centres from which the air is exhausted by an exhaust fan or similar apparatus or source of draught such as a heated chimney. When the mass is dry and cool, the seed is separated by winnowing, preferably by means of a combined sifter and wind current winnowing machine. The seeds are then cleaned from dirt and fibre, and may be sold either whole, or ground into meal, or pressed into cakes, or they may be mixed with other feeding materials. The fibre makes a good litter of considerable commercial value.

—L. de K.

*An Improved Apparatus for Airing or Rousing Brewers' Wort or other Liquids.* F. R. Stone, Liverpool. Eng. Pat. 11,936, June 17, 1893.

THE improved rouser consists of a covered spoon-shaped vessel, perforated with holes, which is attached to the discharge pipe of a suitable pump; the whole being fixed permanently, or temporarily—as may be desired—to the side of the fermenting vessel. The wort being drawn up by the pump, falls from the rouser in thin spreading streams, and is thus aerated. —H. T. P.

*Improved Method of and Apparatus for making Vinegar and Maturing Spirits.* R. H. Leaker, Bristol. Eng. Pat. 15,475, August 15, 1893.

THE object of this invention is to accelerate the process of vinegar making, and to prevent as far as possible the loss of the volatile bodies, such as aldehyde, ethers, &c., produced during acetification, on which the aroma and market value of the vinegar depend. The apparatus employed consists of a closed rectangular chamber, of which the upper portion is fitted with a series of inclined shelves or frames covered with some kind of woven material. The shelves slide in grooves, and are inserted through openings in the side of the vessel, so arranged that any one shelf may be withdrawn for cleaning purposes, &c. without disturbing the rest. The lower part of the chamber acts as reservoir for the wash. By means of a pump and sprayer the wash is continuously discharged in a fine spray on the surface of the uppermost shelf, from which it gradually percolates over and

through the other shelves, thus exposing a large surface to evaporation. An air-blower is also provided and serves to circulate filtered or unfiltered air, mixed with a portion of the vapour generated from the alcoholic wash through the apparatus. The bulk of the volatile vapour is, however, continuously drawn by suction through a condensing worm attached to the cover of the chamber, the condensed products being returned to the wash reservoir. In addition to the above, attenuating coils are provided, for the purpose of regulating the temperature of the wash; and a steam pipe passing through the bottom of the chamber, by means of which the whole apparatus may be sterilised or dried, prior to recharging. Drawings of the apparatus accompany the specification.—H. T. P.

*Improvements in the Process and Apparatus used in Brewing.* A. Zimmer, Paris, France. Eng. Pat. 23,998, December 13, 1893.

THE malt, instead of being merely crushed as ordinarily, is separated by a complete process of "high-milling" into malt-flour, and certain sub-products, such as husk, germs, &c. For brewing beer, the sub-products are mashed with water, and the wort rich in diastase thus obtained employed to saccharify the main product (the flour). The main wort, if turbid, may be centrifuged; it is then boiled with hops, cooled to 50° C. and passed through a centrifugal machine, in order to separate the suspended matters, and aerate it prior to fermentation. A detailed description accompanied by drawings, is given of an improved centrifugal machine, by using which, the violent frothing obtaining in the older forms, is avoided.—H. T. P.

*Apparatus for Distilling and Sterilising Water.* J. Nagel, Chemnitz, Saxony. Eng. Pat. 2588, February 6, 1894.

See under I., page 423.

*Improved Process for the Manufacture of Beer.* J. C. Pennington, Paterson, New Jersey, U.S.A. Eng. Pat. 3642, February 20, 1894.

THE object of the process is to brew beer absolutely free from disease germs. To this end the wort is completely sterilised by intermittent heating; a pure yeast culture used for pitching, and fermentation effected in a closed vessel provided with a safety valve, &c. Finally the beer is stored in sterilised vessels.—H. T. P.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY AND WATER PURIFICATION, DISINFECTANTS.

### (A).—CHEMISTRY OF FOODS.

*The Determination of Nitrates in Potable Water.* A. H. Gill. J. Amer. Chem. Soc. 16, 122-132.

See under XXIII., page 663.

*The Determination of Nitrates in Potable Water.* A. H. Gill. J. Amer. Chem. Soc. 16, 133.

See under XXIII., page 664.

*A Rapid and Accurate Method of Determining the Moisture and Oil in Linseed Cakes and other Feeding Stuffs.* A. P. Aitken. J. Amer. Chem. Soc. 16, 114.

See under XXIII., page 669.

*Detection of Salicylic Acid in Food.* K. P. McElroy. J. Amer. Chem. Soc. 16 [3], 198.

See under XXIII., page 670.

### PATENTS.

*Improvements in or Relating to the Preparation of Substitutes for Coffee.* H. Trillich, Munich, Germany. Eng. Pat. 8726, May 1, 1893.

THE inventor claims to have made an improvement in preparing coffee substitutes from cereals, malt, &c. by impregnating the unroasted materials with extract of coffee shells or a decoction of cocoa shells, fruit or leaves of kola nut, or leaves of tea or maté. In using barley, a very good product is obtained when 100 kilos. of the grain are treated with 500 grms. of extract of coffee shells dissolved in three litres of water. The form of the cereals may be chosen in whole grains, hulled grains or grains in a coarsely or finely disintegrated condition. Chicory, figs, pears, and leguminous matters in general, may also be used.

The impregnated material is then roasted in the usual manner. The flavour will, of course, depend on the choice or proportion of the ingredients of the extract.—L. de K.

### (B).—SANITARY CHEMISTRY AND WATER PURIFICATION.

#### PATENTS.

*A New Compound or Mixture for Purifying Sewage and Foul Water or Liquid.* G. Whalley, Chorley, Lancashire. Eng. Pat. 9359, April 28, 1894.

THE mixture consists of ferric oxide (1 part), bauxite (1 part), and brown vitriol (2 parts). It is heated with sulphuric or hydrochloric acid, a small quantity of nitric acid being added if necessary. The mixture is employed in proportion to the nature of the sewage, &c. to be purified. The effect is to cause quick precipitation of the organic matter present in the water.—N. H. J. M.

*An Improved System for the Purification and Filtration of Sewage, Foul Water from Sewers, Manufactories, and other Sources.* G. B. Sharples, Manchester. Eng. Pat. 12,265, May 5, 1894.

A SYSTEM of continuous flow precipitation tanks is employed, combined with perforated slabs carrying suitable filtering media or chemicals, or both. By means of suitable divisions across the tanks, the water can be made to pass upwards or downwards as may be required.—N. H. J. M.

### (C).—DISINFECTANTS.

#### PATENTS.

*A Liquid for use as a Fertiliser and Insecticide, and for other Agricultural and Horticultural Purposes, applicable also as a Deodorizer and Disinfectant.* S. Elliott, Newbury, Berks. Eng. Pat. 8910, April 7, 1894.

See under XV., page 652.

*Improvements relating to the Burning of Sulphur for Disinfecting Purposes.* H. H. Lake, Southampton Buildings, Middlesex. Eng. Pat. 4395, April 14, 1894.

THE apparatus consists of a sulphur candle, made of a block of sulphur with a wick, enclosed in a container made of some porous material, such as paper. This rests on a perforated metal cap placed in a metal cylinder, into which a suitable quantity of water is introduced. The water prevents the fire from being transmitted to surrounding objects, and is gradually and constantly supplied to the sulphur. On reaching the heated sulphur, the water is vaporised and forms sulphurous acid with the sulphurous oxide.—N. H. J. M.

*Improvements in Disinfectants.* I. S. McDougall and J. T. McDougall, London. Eng. Pat. 11,679, April 14, 1894.

IRON salts are rendered more effective as disinfectants by the addition of aluminium or magnesium salts. Ferrous and ferric chlorides and sulphates, or ferric nitrate or acetate may be used singly or mixed. To increase both disinfecting and precipitating power an aluminium salt such as sulphate (40 parts) is mixed with the iron salt (60 parts). To increase the hygroscopic effects a magnesium salt is added in amounts varying from 10 to 20 per cent.—N. H. J. M.

*Improvements in Sulphur Candles and their Holders.* C. T. Kingzett, Chislehurst, Kent. Eng. Pat. 11,807, April 14, 1894.

THE difficulty of igniting an ordinary mass of sulphur is entirely overcome by using a wick of cotton, or asbestos impregnated with sulphur (finely divided sulphur or sulphur dissolved in carbon bisulphide may be employed), or a wick with a mixture of sulphur and some oxidising agent as potassium chlorate. Instead of a wick, a fuse consisting of a mixture of sulphur and potassium chlorate, sodium nitrate, or permanganate, may be employed. With the wick or fuse the candle will burn until all the sulphur is used up.

The candle may be burnt in a double cylindrical holder containing water or any other medicament, such as Sanitas oil. The evaporation of the water renders the sulphurous anhydride much more effective by securing more complete contact between the sulphurous anhydride and the articles which require to be disinfected.—N. H. J. M.

*Improvements in Insecticides and Fungoid Exterminators.* W. S. McDougall and J. T. McDougall, London. Eng. Pat. 11,944, April 14, 1894.

PRECIPITATED sulphur prepared by any well-known process is employed. Sulphur in this very fine state of division is much more efficient and can be distributed over a much greater space than flowers of sulphur.—N. H. J. M.

*Improvements in Fumigants.* W. S. McDougall and J. T. McDougall, London. Eng. Pat. 12,406, April 14, 1894.

THE improvement consists in employing meal-flours as binding materials in the production of fumigants. For fumigants for use on vegetable growths and for disinfecting purposes respectively, the following mixtures are employed:—(1.) Tobacco extract in powder (4 parts), middlings (4 parts), water (2 parts). (2.) Sulphur powder (5 parts), common quality of wheat-flour (3 parts), water (2 parts). The ingredients are mixed into a dough, and dried. Saltpetre may be added to render the product self-consuming when ignited.—N. H. J. M.

## XIX.—PAPER, PASTEBOARD, Etc.

*Spontaneous Combustion of a Lamp Shade.* A. Dupré, Times, May 23, 1894.

See under *Analyst and Solent Notes*, page 670.

*The Causes of the Difficulty of Sizing Paper in the Hot Season.* E. Muth. *Dingl. polyt. J.* 290, 261.

THE often-observed difficulty of sizing paper during hot seasons is due to the resin soap used for this purpose. In consequence of the higher temperature of the air, the pulp in the beaters often reaches a temperature of 25°C., and under these conditions, favoured by the violent agitation of the whole mass, the exceedingly fine globules or flakes of resin formed by the action of the alum or aluminium sulphate upon the resin soap, instead of immediately filling up the pores of the fibre and incrusting it, unite to larger aggregates of a sticky character, and which, therefore, are no longer capable of serving the purpose of sizing, but may even cause the paper to adhere to, and tear upon, the calender bowls. As it is scarcely practicable to reduce the temperature of the contents of the beaters, the only remedy is to shorten the time occupied by the sizing operation as much as possible, and to allow, during hot seasons only, from 15 to 20 minutes for the sizing, instead of the usual 45 or 60 minutes. It is also necessary to dry the paper upon the machine very gradually. With these precautions the sizing of paper will be found to offer no difficulty during hot weather.—C. O. W.

## PATENT.

*Improvements in Artificial Whalebone for Dresses and Corsets.* E. Tourrette, Brussels, Belgium. Eng. Pat. 20,708, November 1, 1893.

VEGETABLE parchment possesses none of the drawbacks proper to other whalebone substitutes, and has been found to improve in quality under the influence of the temperature of the human body; it therefore forms the claim of this patent.—A. G. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Stability of a 1 per mille Solution of Corrosive Sublimé exposed to the Atmosphere.* Taurat. *Comptes rend.* 117, 1081—1082.

ACCORDING to Leo Vignon, a solution of corrosive sublimate in distilled water containing 1 per mille of dissolved salt, is quickly altered by exposure to air, a white precipitate being rapidly formed, and the solution impoverished to about half the original strength at the end of a week. The author finds that this effect is due to free ammonia in the air, and that if ammonia be absent, no precipitation or loss of strength occurs.—C. R. A. W.

*Cinchonifine.* E. Jungfleisch and E. Leger. *Comptes rend.* 119, 535—538.

CINCHONIFINE is isomeric with cinchonine, being produced therefrom by heating to 120° in presence of sulphuric acid mixed with its own weight of water. Several alkaloids are thus formed; cinchonifine is found amongst those which either does not dissolve; and from amongst these it is distinguished by being insoluble in 50 per cent. alcohol. It melts at 273°C., or some 1° above the melting point of cinchonine. It is dextro-rotatory, the rotatory power

increasing with the concentration of the solution. It forms two well-marked classes of salts, for the most part readily soluble in water, and crystallisable; several of these are described; also the chloromethylate, mono-iodomethylate, di-iodomethylate, mono- and di-iodethylates, and the mono- and di-bromethylates. (This Journal, 1894, 58).

—C. R. A. W.

*Essence of Tarragon; its Transformation into Anethol.* E. Grimaux. Comptes rend. **117**, 1089—1092.

The essential oil contained in Tarragon is stated in various textbooks to consist almost entirely of crystallisable anethol, although this statement is not substantiated by any direct observation. Gerhardt found that it is a fluid, and only isomeric with anethol, although giving the same oxidation products. The author finds that anethol is entirely absent, but an isomeric oxidised substance,  $C_{10}H_{12}O$ , *estragol*, is present, boiling at  $216^{\circ}.5-212^{\circ}$  (uncorrected), or about  $16-17^{\circ}$  lower than anethol. This body does not solidify at  $-43^{\circ}$ ; its specific gravity is  $0.9325$  at  $15^{\circ}$ ; and the index of refraction,  $nd = 1.523$ . When heated on the water-bath for 24 hours with three or four times its volume of concentrated alcoholic potash, estragol is largely converted into the higher-boiling isomeride anethol, melting at  $21.5^{\circ}$ . The original estragol, accordingly, appears to be an allyl derivative of phenol, whilst anethol is the corresponding propenyl derivative, respectively,

since the relationships between the two (as to difference in boiling point, about  $16^{\circ}$ , and transformation of lower-boiling isomeride into the other by heating with potash) are the same as those subsisting between eugenol—

and iso-eugenol—

between the corresponding methyl eugenol and methyl iso-eugenol; and between safrol—

and iso-safrol—

Eykman's *chavicol* (from betel nut), on the other hand, is probably a stereo-chemical isomeride of anethol.

—C. R. A. W.

*A New Source of Rhodinol.* P. Monnet and Ch. Barbier. Comptes rend. **117**, 1092—1094.

The essential oil of pelargoniums, cultivated in Algeria and the south of France, contains a considerable proportion of *rhodinol*,  $C_{10}H_{14}O$ , the odorous constituent of oil (otter) of roses. By fractional distillation *in vacuo*, a portion boiling at  $123-125^{\circ}$  under a pressure of 14 mm. is isolated; this is heated in closed vessels to  $140^{\circ}$  for eight hours with its own weight of acetic anhydride; the product is washed with alkali to remove acetic acid, and finally with water, and again fractionated *in vacuo*; the portion passing at  $128^{\circ}-129^{\circ}$  under 14 mm. pressure is pure rhodinol acetate, identical in all respects with that from oil of roses. On saponification by alcoholic potash it furnishes rhodinol, boiling at  $124-125^{\circ}$  under 14 mm. pressure, identical with that obtained from rose oil, not only as regards physical and organoleptic properties, but in its chemical reactions; by oxidation it forms an aldehyde, *rhodinol*,  $C_{10}H_{16}O$ , which combines with bisulphites, hydroxylamine, and phenylhydrazine, and is oxidised by ammoniacal silver solution to *rhodinolic acid*,  $C_{10}H_{16}O_2$ . Rhodinol combines with bromine to form a tetrabromide,  $C_{10}H_{14}Br_4O$ ; chlorine forms a liquid product,  $C_{10}H_{14}Cl_2$ , from which a terpene is obtainable, boiling at  $177-178^{\circ}$ , and forming a tetrabromide, melting at  $123^{\circ}-124^{\circ}$ .—C. R. A. W.

*Presence of Camphene in Spike Oil.* G. Bouchardat. Comptes rend. **117**, 1094—1096.

Oil of spike (*Larandula spica*) contains a small proportion of a camphene, isolated by distillation, whereby 9 grms. of liquid passing at  $155-160^{\circ}$  and 15 grms. passing at  $160^{\circ}-165^{\circ}$  were obtained from 4 kilos. of oil; the monochlorohydrate,  $C_{10}H_{17}Cl$ , obtained from these fractions was solid and levorotatory, whereas the hydrocarbon itself was dextrorotatory. Alcoholic solution of potassium acetate decomposes the hydrochloride from camphene at  $80^{\circ}$ , but has practically no action on that from turpentine; the hydrochloride obtained from spike oil was almost entirely decomposed in this way, solid camphene in an imperfectly pure condition being isolated from the product of the action.

—C. R. A. W.

*Synthetic Borneols.* G. Bouchardat and J. Lafont. Comptes rend. **118** (1894), 248—250.

Bertram and Walbaum (J. prakt. Chem. 1894) have obtained an isomeride of natural borneol by heating camphene at  $50-60^{\circ}$ , with a mixture of glacial acetic acid and sulphuric acid. The authors have succeeded in preparing a similar compound from terebenthene. The following method of preparing camphene borneol is more rapid than that of Bertram and Walbaum (*loc. cit.*):—Equal parts of camphene and glacial acetic acid are mixed with one-third the weight of sulphuric acid diluted with acetic acid. The reaction is moderate and instantaneous, the chief product being the acetate of the borneol together with a small quantity of a new compound of camphene, and the borneol having the formula  $C_{20}H_{32}O$ , and boiling at  $187^{\circ}$  under a pressure of 20 mm.

Camphene borneols are more readily soluble in light petroleum spirit than terebenthene borneols and the natural compounds, they form smaller crystals than the former and sublime readily. Camphene borneols are also less stable than their isomerides, inasmuch as they decompose when heated a little above  $250^{\circ}$ ; on oxidation the same camphor is obtained that results from other borneols.—A. R. L.

*The Odour of Benzoic Acid with Remarks on other Odorous and Inodorous Bodies.* J. Passy. Comptes rend. 1894, **118**, 481.

See under Analyt. and Scient. Notes, page 670.

## PATENTS.

*Improvements in the Manufacture of Orthohalogen-phenol, and in the Production of Pyrocatechine therefrom.* H. Baum, Frankfurt-on-the-Main, Germany. Eng. Pat. 12,942, July 1, 1893.

The employment of phenol for the manufacture of pyrocatechin (pyrocatechol) has hitherto been regarded as a technical impossibility owing to the difficulty of brominating or chlorinating it so as to form the ortho-halogen-phenol. If bromine vapour or chlorine is admitted into phenol heated to  $150-180^{\circ}$  C. ortho-bromo or ortho-chloro-phenol are formed in abundant quantities, and are practically pure. These products, purified in a manner described in the specification, on fusion with caustic potash at a high temperature, under pressure, yield pure pyrocatechol.—J. C. C.

*Process for Obtaining an Iron Albumen Derivative from Animal Organs.* B. Wilcox, London. From C. F. Boehringer and Soehne, Mannheim, Germany. Eng. Pat. 16,589, September 4, 1893.

This is a process for obtaining an iron albumen derivative from animal organs, such as the liver, spleen, and kidneys, and consists in gradually heating the reduced or minced organs with water to boiling point, and extracting and mixing the solution with dilute acid until a brownish yellow precipitate forms.—J. C. C.

*An Improved Manufacture of Artificial Musk.* W. Mallman, Roermond, Holland. Eng. Pat. 1018, February 24, 1891.

A mixture of valerate of lime and toluylate of lime is distilled in the dry state. The heavy ketone is separated from the distillate by washing repeatedly with dilute soda solution; this ketone is redistilled, and the products distilling up to 235° to 245° C., are finally nitrated, forming trinitro-iso-butylketone. In this process the inventor obtains a large yield and but little by-product, and also the product produced has a more pleasant and lasting odour than the known trinitrobutyltoluene.—J. C. C.

*Improvements in Photographic Developers.* C. D. MacL, London. From The Actien Gesellschaft für Anilin-Fabrikation, Berlin, Germany. Eng. Pat. 11,872, June 16, 1893.

By introducing further substituting groups, viz., the amino or hydroxyl group into the benzene nucleus of the para-phenylenes, their developing properties are enhanced to such a degree, that the products may be used in the presence of carbonates or sulphites of alkalis, even with bisulphites.

Aminopara-phenylenediamine, oxypara-phenylenediamine or aminopara-toluenediamine are the developers claimed.

—J. C. C.

*An Appliance for Washing Photographic Plates and Prints.* W. Thomson, Manchester. Eng. Pat. 12,734, June 29, 1893.

The inventor claims a method of washing photographic plates or prints by a continuous current of pure water, and the use of a moveable partition as a means of lifting the plates as well as for directing the flow of the water. For details of this appliance the original specification must be consulted.—J. C. C.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

### PATENTS.

*Improvements in or Relating to the Manufacture of Films for Photographic Purposes.* T. H. Blair, Paris. Eng. Pat. 3504, March 14, 1893.

In this process the long slab or table which is usually employed in the manufacture of the body of the film is dispensed with. Instead of it the patentee uses a slowly revolving drum with a slightly roughened surface to receive the substance forming the substratum of the film. This substance is supplied by means of a hopper with a narrow opening of about the ultimate breadth of the film. From the drum the material is carried over bands, rollers, &c., until sufficiently dry. After that it enters a dark chamber, where it is dipped in the sensitive emulsion, then cooled by a blast of cold air, and finally wound on a reeling apparatus consisting of a shaft provided with an apron, upon which slats or bars with projecting portions at the ends are fixed in such a way as to prevent the second layer of film and apron from touching the former, and allow sufficient air space. The film is thus held under suitable tension until it is dry and ready for use.—H. S.

*Improvements in or connected with the Preservation of Photographs Produced on Slate for Decorative or Artistic Purposes.* W. and H. Jones, Bangor, North Wales. Eng. Pat. 10,685, March 31, 1893.

THE part of the slate upon which the photograph is to be produced, is first enamelled white or tinted by a process of slate enamelling. The photograph is then produced on the part so coated, and is then covered with a very thin coating of very pale polishing copal varnish. The slate is then stoved and afterwards polished with very soft rotten stone.

—J. C. C.

*Improvements in the Manufacture of Sensitive Plates and Films for Photographic Purposes.* C. E. Pettitt, Torquay. Eng. Pat. 8956, May 4, 1893.

THE object of this invention is to diminish or prevent halation and solarization. A colored medium is interposed between the sensitive emulsion and its support, so as to obstruct or absorb the actinic rays in their passage to and from the reflecting surface of the support.

The colored medium may be prepared in several ways; for instance, it may be gelatin, albumin, or other vehicle colored with a blue, yellow, or red of such density that it will prevent halation and yet not unduly interfere with the printing property of the negative. Or the colour of the medium may be of a distinctly non-actinic character and may be removed after exposure by chemical means.

—J. C. C.

*Improvements in the Manufacture of Orthoholographenol, and in the Production of Pyrochekine therefrom.* H. Baum, Frankfort-on-the-Main, Germany. Eng. Pat. 12,942, July 1, 1893.

See under XX., page 658.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Researches on the Manner of Combustion of Ballistic Explosives.* P. Vieille. Comptes rend., 1894. 118, 346–347, and 458–461.

At present, the probable behaviour of a new powder when fired in any service weapon cannot be accurately foretold from its physical characteristics or its chemical composition: experiments must be made with it in a known arm, and these experiments are especially laborious and costly in the case of slow-burning powders which require the use of heavy charges. Piobert experimented in 1833 on the rate of combustion of powders under normal pressure; but his belief that the rapidity of combustion is unaffected by pressure has long been considered untrue, while the hypothesis that the combustion of the material proceeds in parallel layers, under pressure as well as in the open air, although accepted for powders of high density and affording the *raison d'être* of large grain explosives, does not perfectly stand the test of exact experiment. The author has therefore sought to imitate the conditions obtaining in the gun at the moment of discharge by observing the behaviour of the powder when exploded in a closed vessel under a pressure of several thousand atmospheres. In this studying, however, the development of pressure by combustion in a closed and perfectly resisting vessel, where the pressure at any given moment depends only upon the fraction of the charge which has been burnt, the conditions are not exactly those met with in the gun where the movement of the projectile allows expansion to take place and thus affects the specific heats of the gases.

In burning large grain powders, if combustion proceed by surfaces parallel to the original surface of the grain, the quantity burnt at any moment should be a function of the size of the grain and the rapidity of combustion, and a knowledge of the quantity burnt, calculated from the elements of time and pressure, determines the rapidity of combustion; and these elements added to the energy of the substance determined either theoretically or by pressure measurements, completely evaluate the powder for ballistic

purposes. Since by combustion in a closed chamber, pressure at any instant depends upon the fraction ( $x$ ) of the charge burnt, the formula—

$$P = \frac{f \Delta}{1 - d \Delta}$$

may be exchanged for—

$$x = \frac{1}{1 + \frac{1 - a \Delta}{1 - \frac{\Delta}{\delta}} \cdot \frac{P_0 - P}{P}}$$

where  $P_0$  represents the final maximum pressure,  $\Delta_0$  the mean density of the products of complete combustion,  $P$  the pressure at any moment,  $a$  the volume, and  $\delta$  the density of the explosive. From the curve expressing the relation of  $P$  and  $t$ , both  $x$  and the rapidity of combustion may be found. But the application of this method depends upon the accuracy of the hypothesis of

combustion by parallel layers at high pressures. Experiments were therefore made both with the older black and cocoa powders, and with the newer colloidal gelatinised cotton explosives, by burning in the closed vessel equal charges of grains, geometrically similar but of unlike sizes, cut from the same explosive by means of a saw. If the combustion of the powder proceed by parallel layers, the pressure should vary as a function of time, and hence with the ratio of similarity existing between the sizes of the grains. The following table of results shows however, that for black and brown powders the ratio of similarity does not accord with the ratio of time nor with the inverse ratio of  $\frac{dP}{dt}$ . It would appear that for these powders the law of parallel surfaces does not hold good, but that as the curves of each pair of experiments are practically identical, the powders are disaggregated at very moderate pressures. The colloidal powders on the contrary by the agreement of the different ratios show that they follow the law of combustion by parallel surfaces.

Nature of Powder.	Density of Charge.	Maximum Pressure in Kilos. Per Sq. Cm.	Ratio of Similarity of Charges.	Time observed, in Thousandths of a Second.	Time Ratio.	$\frac{dP}{dt}$ Maximum in Tons per Second.	Inverse Ratio of $\frac{dP}{dt}$ .

—W. G. M'

#### PATENTS.

*Improvements in or relating to Explosives.* E. Kabin, Prague, Austria. Eng. Pat. 11,502, June 12, 1893.

This invention consists essentially in the employment of the nitrates of amido-compounds, especially of those of aniline and teluiline, mixed with ammonium nitrate.

—W. M.

*Improvements in and Apparatus for Igniting Blasting Charges.* C. Roth, Hennickendorf, Germany. Eng. Pat. 23,417, December 5, 1893.

The object of this invention is to ignite blasting charges without danger of producing explosions of firedamp, the production of a flame outside of the hole being dispensed with. Certain gases or liquids are caused to pass through a fine-bore leaden tube, leading to the cartridge, whereby they are brought into contact with substances of such a nature that the action of the gases or liquids generates sufficient heat to cause the explosion of the cartridge. In practice this invention may be carried out when detonators are required by placing some finely-ground lead peroxide in the front end of the detonator above the fulminate. This peroxide is in contact with the open end of a thin lead, rubber, or papier maché tube of a sufficient length to ensure

the safety of the person firing the charge, and communicating at its other end with a gas-generating apparatus. When sulphurous acid is turned on it drives the air out of the tube and detonator through a small tube or passage provided in the material employed for tamping, and, coming in contact with the lead peroxide, generates sufficient heat to explode the detonator. In a similar manner antimony and chlorine, spongy platinum or platinised asbestos and hydrogen may be employed. Another method of working consists in placing a small quantity of a mixture of potassium chlorate and sugar in the detonator or charge and forcing sulphuric acid along a leaden tube which is in contact with the mixture, when explosion takes place.

Details and drawings of the several methods of carrying out this invention are given in the specification.—W. M.

*An Explosive Composition.* A. Maurette, Toulouse, France. Eng. Pat. 4626, March 5, 1894.

"This invention consists in a composition of materials for use as an explosive":—Saltpetre 640, powdered wood-charcoal 50, wood-ashes 55, chlorate of potash 5, and flowers of sulphur 25 parts.—W. M.

*An Improved Compound for use in the Manufacture of Matches.* H. Priester, Lauenburg, Pomerania. Eng. Pat. 5939, March 21, 1894.

THE inventor claims "the utilisation of magnesium either alone or alloyed with other metals to form combustible compounds capable of being applied by dipping," matches coated in this way giving a coloured light and scattering sparks when burning. It is stated that a much more brilliant result is obtained when the magnesium is alloyed with copper, calcium, or zinc and then added to one of the known firing mixtures.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS, ETC.

*Some Laboratory Apparatus.* A. Bidet. Comptes rend. 1894, 118, 478—481.

**SIPHON LEVEL REGULATOR.**—This is an S-shaped tube (Fig. 1) with a side tube S sealed on a little above the lower bend. The long arm O is inserted in the apparatus

Fig. 1.

Fig. 2.

in which the constant level of liquid is required, and the hole O is placed at the side of the tube to prevent air from the boiling water passing up into the siphon tube. Water flows continuously through A, and may then pass through either S or B, the tube BO forming a siphon which may act in either direction according as the level of the water in the apparatus to be supplied is above or below that for which the instrument is regulated. The hole O, by free admission of air, serves to prevent the tube S from acting as the limb of a siphon.

**SAFETY TUBE ARRANGED TO PREVENT SPLASHING.**—This apparatus (Fig. 2) serves for introducing liquids into a vessel and for leading off gases by the side tube. Regurgitation quietly transfers the liquid in the middle cylinder into the upper funnel through the recurved tube at O, whence it returns after the pressure has again become normal. The lower tube is adapted to a tubulure by a cork with one perforation.

**INTERNALLY-COOLED CONDENSER.**—In this instrument (Fig. 3) the vapours entering by the upper tube are condensed in the annular space surrounding a water-cooled glass

tube, sealed into an outer vessel at its lower end, and the condensed liquid passes away through T. An outside water-jacket may be adapted to this, so that a double cooling surface is presented for condensation.

Fig. 3.

**COMMUTATING ARRANGEMENT FOR CONDENSER.**—By connecting an inverted condenser with R (Fig. 4) and a downward condenser with D, and adjusting the inner circularly-sliding tube I so that the hole O is opposite one or other of these tubes, this instrument allows distillation or cohobation to be carried on at will, or to be effected

Fig. 4.

alternately without delay. The tubes are joined by an india-rubber ring. A cork in the inner tube permits the passage of a separating funnel for the introduction of liquids into the distilling flask.

**SUPERHEATER FOR VAPOURS.**—The superheating is effected by passing the vapour through T (Fig. 5) to the copper spiral, which is enclosed in a brass jacket terminating above in an open cone. The spiral is lined with metallic gauze, and beneath it is placed a suitable burner. The

superheated gases pass away over the bulb of a thermometer *t*. With such an instrument 20 cm high a tem-

Fig. 5.

perature of 300° C. has been attained in the efflux. With a triple Bunsen burner a still higher temperature could be attained.—W. G. M.

*A New Form of Air Bath.* E. Sauer. J. Amer. Chem. Soc. 1894, **16**, 31—33.

In order to ensure a constant temperature, which shall not be limited by the boiling point of some liquid contained in an outer jacket, the author has devised the form of air bath shown in the figure. The bath has a false bottom, perfor-

ated to allow a series of tubes to connect the inside of the oven with the outside air beneath the apparatus through the real bottom; the latter, in addition to corresponding perforations, has a larger central aperture through which the flame of a Bunsen burner can play upon the false bottom and around the connecting tubes; the products of combustion pass away through the sides of the lower chamber between the two perforated plates, the sides being left open. Evaporation is facilitated by the rapid renewal of the atmosphere within the bath by means of the tubes; and experiments are quoted to show that not only is evaporation rapid, but the temperature at different parts of the bath is very uniform.—W. G. M.

*Dropping Flask for Standard Solutions.* F. Vanderpoel. J. Amer. Chem. Soc. **16** [3], 156—157.

The use of burettes for standard solutions involves serious errors (e.g., such as arise from alteration of temperature), which can be avoided by substituting weighing for measuring. The figure shows a simple form of dropping flask for standard solutions, which has been found convenient. The

figure is almost self-explanatory. It suffices to say that the central rod is of glass, and passes through a cork in the upper tubulus of the flask, and is ground into the lower exit tube, thus serving to regulate the outflow. The side tubulus is used for filling the flask. The whole apparatus can be slung to a hook on the balance or supported on a light tripod in the manner of a weighing bottle.—B. B.

*Apparatus for Fractional Distillation.* C. W. Volney. J. Amer. Chem. Soc. **16** [3], 160.

The apparatus shown in the figure is similar to an ordinary dephlegmator, save that the central tubes constituting the

passage for the vapour from the flask to the condenser are not trapped by liquid. The author states that in spite of this, fractionation proceeds readily, and that products of nearly constant boiling point are obtained by a single repetition of the distillation.—B. B.

#### PATENTS.

*Improvement for the Determination of Butter Fat in Milk.* C. R. C. Tichborne, Dublin, and C. J. Thompson, Bray. Eng. Pat. 7547, April 13, 1893.

The apparatus consists chiefly of a circular metallic basin, provided with a cover, round the inside of which the graduated milk-bottles are placed in compartments. The basin may be filled with hot water, or the arrangement may be used as a steam-jacket by passing steam through an opening of the top of the cover.

The inventors claim, as chief improvement, the special application of the heat from the top of the apparatus instead of from the bottom of the tank, so as to avoid the chilling of the bottles, and an arrangement by which currents of air produced by the revolution of the machine fall back upon the stems containing the isolated fat. A minor improvement consists in the use of a screw regulating the height of the shaft carrying the frame and holding the bottles.—L. de K.

*Improvements in Apparatus for Detecting and Estimating the Proportion of Fire-damp or other Inflammable Gases in the Atmosphere of Mines and other Spaces.* G. Fletcher, Derby. Eng. Pat. 12,261, June 22, 1893.

This is a patent for an instrument based on the known fact that a luminous spiral of wire glows more brightly when the surrounding air contains a small proportion of some inflammable gas. The instrument consists of two identically similar spirals of fine platinum wire. One of these is enclosed in an air-tight tube containing air and having the upper end closed by glass. The other spiral is contained in a similar tube of wire-gauze having the upper end likewise closed by glass. The spirals are observed through a screen of ground glass or other suitable substance. When a current of electricity is passed through both spirals in air they glow equally, but if they are introduced into an atmosphere containing an inflammable gas, the spiral in the open or wire-gauze tube glows the more brilliantly, the brilliancy increasing with increase in the proportion of inflammable gas present. By a pinion wheel fitted with a pointer the spiral in the closed tube may be approached to, and that in the wire-gauze tube reeled from the ground glass disc till the two appear equally luminous. The circle over which the pointer moves is graduated by experiment with measured percentages of gas, and afterwards enables the operator to directly read off the percentage present. Any small storage battery, such as those in use for miners' lamps, may be used as the source of the electricity.—L. T. T.

*An Improved Actinometric Pyrometer.* C. Latarche, Lempère, near Verdun, France. Eng. Pat. 18,652, October 5, 1893.

This instrument consists of a chamber *l* containing a thermometer *t*, and surrounded by a cistern of water *a*, containing a second thermometer *t'*. The chamber *l* is closed except for the circular opening *o*. The instrument is placed against the wall *b* of the furnace in such a way that the opening *o* is against a corresponding opening *c* made for that purpose in the wall *b* of the furnace. The bulb of the thermometer *t* and the inside of the chamber *l* are blackened. The water in the cistern *a* is kept at about the boiling point by the heat from the furnace wall, and the thermometer *t* is also warmed by the heat of this water-jacket. But in addition the bulb of the thermometer *t* receives the heat rays of the furnace through the opening *c o*, and therefore registers higher than *t'*, which of course shows the temperature of the water. This difference, read on the scales at the front *d* of the apparatus, gives an

index of the furnace temperature, the difference being dependent on the size of the opening *c o*, the distance of the bulb of *t* from this opening, and the heat of the furnace chamber. By graduating the instrument with known furnace-heats, and regulating the size of the opening *c o*

and the distance of the bulb of *t* from that opening, any degree of sensitiveness may be attained, and each degree-centigrade of *t* in excess of *t'* may be made to represent any chosen number of degrees of heat. For moderate furnace-heats the author suggests regulation, so that each degree excess of temperature of *t* represents 10 °C. of actual temperature. For very high furnace-heats it is advisable to reduce the sensitiveness by reducing the size of the opening *c o* by introducing a diaphragm there. The instrument is best hinged to the furnace wall, so that during stoking, &c., it may be swung on one side to prevent as much as possible the accumulation of dust in *l*. The patentee claims that the instrument does not get out of order, gives very reliable results, and that the temperature can at any time be read off at once.—L. T. T.

#### INORGANIC CHEMISTRY.— QUANTITATIVE.

*The Determination of Nitrates in Potable Water.* A. H. Gill, J. Amer. Chem. Soc. **16**, 122–132.

STIMULATED by the unfavourable criticisms of Hazen and Clark (J. Anal. Appl. Chem. **5**, 1) upon the phenol-sulphonic acid process of determining the nitrates in water, as proposed by Sprengel and revived by Grandval and Lajoux, the author has re-investigated the method, which he now considers to be more delicate, trustworthy, and accurate than any process yet published. The best reagent is pure phenol disulphonic acid (probably—

which with nitric acid gives picric acid even in the cold; it is prepared by heating in (not upon) a water-bath at 100° for six hours, a flask containing 3 grms. of pure phenol and 37 grms. of pure sulphuric acid

sp. gr. 1.840); the purity of the product thus obtained has been proved by the analysis of the re-crystallised barium salt. It is apt to crystallise out upon standing, but is readily re-dissolved on warming. Among other reagents, equal parts of phenol and sulphuric acid gave brown colours, which could not be accurately matched; mixtures of the ortho and para-sulphonic acids from a 5 per cent. solution of phenol gave a fairly good, but sometimes reddish shade; while pure ortho-phenol mono-sulphonic acid gave a precipitate with ammonia and a bluish-green coloration. The disulphonic compound in 7.5 per cent. solution yielded a pure yellow, which did not change upon standing. In the tests of the process a standard solution of potassium nitrate containing 0.1 part of nitrogen per 100,000 was employed, and for certain tests a solution of sodium chloride, containing 7 parts of chlorine per 100,000, was also used. 1 cc. of the nitrate solution was diluted to 5 cc., and evaporated in a porcelain dish 2½ inches in diameter; and the residue was moistened with ten drops (0.7 cc.) of the phenol-sulphonic acid, contact being ensured in every part by rubbing with a glass rod. 7 cc. of water was then added and afterwards 3 cc. of ammonium hydrate, the liquid being well stirred after each addition. When the colours could not be accurately compared in the dishes, tubes 1½ inches deep and ½ inch in diameter were employed. Variations in the process are dealt with under several heads:—

*Method of Treatment:* The picric acid reaction gives low results at 0° C., but good results alike at 100° and at the normal temperature. The addition of phenol or of phenol sulphonic acid to the water before evaporation offers no advantages. *Quantity of Acid used:* When little chlorine is present, the amount of acid used is of little consequence, provided that it suffice to cover the residue; but the use of less than 10 drops may cause loss of nitric acid.

*Evaporation:* A slight loss (equal to about 1 per cent. of the nitrogen present) occurs when the evaporation is conducted at 20° over sulphuric acid, or at 100° on a steam bath, if the dish be removed immediately the residue is dry; a greater loss results from the more prolonged evaporation at 65° C. The addition of sodium carbonate before evaporation has no marked effect, while the use of sodium acetate rather increases the loss of nitrogen. A large volume of water evaporated gives lower results than a small volume, but the difference is not great. Heating of the dried residue even to 65° C. causes a distinct loss of nitrogen. *Effect of Chlorine:* In waters containing less than 2 parts of chlorine per 100,000 the halogen exerts no appreciable influence, but with 7 parts per 100,000 the evaporation of a comparatively large volume (10 cc.) at 100° may entail a loss of 30 per cent. of the nitrogen, but this loss may be reduced to 6 or 7 per cent. by using only 1 to 5 cc. of the water and evaporating at 20° over sulphuric acid.

*Comparison with Standards:* The errors due to imperfect matching increase (actually but not relatively) with the percentage of nitrogen, ranging from 0.002 to 0.003 part of nitrogen for a sample containing 0.05 part per 100,000 to 0.005 part for one with 0.1 per 100,000. The readings should be taken rapidly, and the eye occasionally rested by looking intently at a blue surface. The author recommends for waters with much nitrogen the use of a quantity which will give a reading of about 0.07; when the chlorine also is high, evaporation should be conducted *in vacuo* over sulphuric acid, while if it exceed 7 parts per 100,000 it should be removed by silver sulphate free from nitrates. With ground water 10 cc. of a portion, previously decolorised by alumina in the cold, is evaporated on the steam bath, the dish being removed before the disappearance of the last drop of liquid. For the standard, 0.72 gm. of potassium nitrate is dissolved in 1 litre of water, 10 cc. of the solution is evaporated *in vacuo*, treated with acid, and made up to a litre, 10 cc. of this contains 0.1 part of nitrogen per 100,000. Portions withdrawn for test are made alkaline as required. The process does not determine nitrogen in nitrites, since nitrous acid gives nitro-phenol with phenol sulphonic acid, and this is colourless in dilute solutions.

—W. G. M.

*The Determination of Nitrates in Potable Water.* A. H. Gill. J. Amer. Chem. Soc. 16 [1], 193—197. (This Journal, 1894.)

**PART II.—REDUCTION TO AMMONIA.**—The chief objections to any method for estimating nitrates in water, based upon the reduction of the nitrates to ammonia, are caused by (1) the corrections to be applied (*e.g.*, that for free ammonia); (2) the risk of obtaining ammonia from the organic matter present; (3) the variation in the colour produced by the Nessler solution, especially when distillation is omitted. The variation is largely due to the presence of hydroxylamine, which is formed to some extent in place of ammonia. The irregularity of the results of the method is shown in tables given by the authors, in which errors of from 5 per cent. to 20 per cent. of the true quantity of nitrate are quoted. The results are generally lower than those obtained by the phenol sulphonic acid process, which yields figures that are, on the whole, nearer the truth. This holds even in presence of chlorine, in which contingency the reduction process is usually considered preferable. The many processes of reduction by means other than the use of aluminium—*e.g.*, finely-divided iron and an acid—are primarily designed for the analysis of commercial nitrates and not for dealing with such small quantities of nitrates as are found in potable waters. Harrow's method (J. C. S. 1891, Trans. 320; this Journal, 1891, 727) is sensitive to 0.04 part of nitrogen per 100,000, *i.e.*, 20 times less delicate than the phenol-sulphonic acid process. The author states, in conclusion, that improvement in the determination of nitrates in potable waters is to be sought in the formation of organic nitro-compounds of high colouring power and constant composition.—B. B.

*General Method for the Volumetric Determination of Silver in any Form.* G. Deniges. Comptes rend. 117, 1078—1081.

THE volumetric determination of silver by means of an alkaline chloride and potassium chromate as indicator requires an exactly neutral solution. Moreover, the presence of certain organic substances interferes with the accuracy, whilst only substances soluble in water can be treated. The Volhard-Charpentier process with potassium thiocyanate permits of the examination of silver compounds soluble in nitric acid, but is inapplicable in the case of substances not soluble therein, such as silver chloride. On the other hand, since all silver compounds are soluble either in ammonia or in potassium cyanide solution, the following process can be used in all cases. The substance is dissolved in ammonia, or, if not soluble completely therein (*e.g.*, silver iodide), in ammonia together with a sufficient quantity of standard potassium cyanide solution. In many cases the solution is best effected by dissolving in nitric acid and supersaturating with ammonia. A definite quantity of potassium cyanide is then added with a little potassium iodide as indicator, and then decinormal silver nitrate until a permanent turbidity is perceptible. This occurs when the total silver present is faintly in excess of that corresponding with the cyanide as regards formation of argentocyanide of potassium,  $\text{AgCy}$ ,  $\text{KCy}$ ; so that if the cyanide solution employed is standardised in terms of the silver nitrate solution, the silver present in the substance tested is known from the difference between the volume of silver nitrate corresponding with the cyanide added, and that actually employed in the titration. Variations in the quantity of free ammonia present do not affect the result; nor does the presence of caustic or carbonate of potash or soda, or of chlorides, bromides, phosphates, &c. Moreover, pure potassium cyanide solution of about 1 per cent. strength is extremely stable at ordinary temperatures, and also at boiling heat in presence of alkalis; so that a standardised solution suffers no change on keeping for a fortnight. Very satisfactory figures were obtained on making tests with known quantities of silver chloride, bromide, iodide, phosphate, chromate, and sulphide. In this way precipitated silver chloride, iodide, &c., may be volumetrically determined, and thus the quantity of chlorine, &c. present in liquids containing organic matter (*e.g.*, urine,

blood, &c.) may be easily ascertained. Similarly, precipitates (organic or otherwise) containing silver may be readily titrated.—C. R. A. W.

*Experiments on the Estimation of Graphite in Pig-Iron.* F. L. Crobaugh. J. Amer. Chem. Soc. 1894. 16, 101–108. From several experiments with different solvents and details of treatment, it appears probable that the graphite may be estimated in pig-iron with sufficient accuracy for commercial purposes as follows:—Dissolve 5 grams of the iron in 125 cc. of nitric acid (1·135 sp. gr.), and add immediately 12 cc. of a 40 per cent. hydrofluoric acid solution; boil for five minutes after complete solution, and then filter through a double tared filter-paper, wash with dilute hydrochloric acid until all iron is removed, and then with alcohol, ether, and ammonia successively, or with ammonia alone. The filter-paper is dried at a temperature below 100° C. and weighed; it is afterwards ignited, and the weight of the residue is deducted from that of the mixed graphite precipitate. The final residue should be practically nil, owing to the solvent action, first of the hydrofluoric acid, and then of the ammonia. A trace of some colouring substance, probably combined carbon, is yielded to the ammonia wash-waters, but is rapidly removed. The hydrofluoric acid etches the beaker in which the solution is effected to some extent, but no severe corrosion was noticed even after several treatments. The ammonia and the alcoholic and ethereal washings leave a black mirror-like deposit on evaporation, which is soluble in warm dilute ammonia; but that from the ammoniacal liquid will not dissolve in alcohol or ether. The dissolved matter separates in each case in brownish flocks. This is a matter, however, which the author is still investigating. Results are sufficiently concordant.—W. G. M.

*The Analysis of Steel.* H. K. Bunber. Iron and Steel Institute, Spring Meeting, 1894.

THE analysis is as follows:—200 grains of steel drillings are taken, to which is added 1 oz. of distilled water with 2½ oz. of pure nitric acid, sp. gr. 1·42. When the violent action has ceased, it is boiled for some time until all further action ceases, and the steel is completely dissolved. To this there is added 1 oz. of a pure 10 per cent. solution of sodium carbonate. The whole is boiled to remove carbonic acid, evaporated to dryness, and ignited in a platinum vessel at a dull red heat. The red powder obtained is then treated with another ½ oz. of the above sodium carbonate solution, evaporated to dryness, treated with hot distilled water, containing about 0·5 per cent. of sodium carbonate, filtered, and washed carefully with the same. If chromium be absent, the solution may be acidulated and evaporated to dryness to remove silica, and the analysis then carried on by the usual methods. The phosphorus is precipitated as ammonia magnesium phosphate, which takes down the arsenic as ammonia magnesium arsenate. These can be weighed together and the arsenic afterwards separated and determined. If chromium be present it is advisable to add the magnesia mixture with a little extra ammonium chloride direct to the alkaline solution, when the phosphorus and arsenic are separated without any trace of chromium.

By the use of this method the author has in several cases found chromium present when it was not even suspected. Where chromium is present there is generally more or less vanadium or molybdenum. These, together with the phosphorus, sulphur, and arsenic, are converted into sodium salts by this method, the iron being converted into insoluble oxide. If distilled water free from sodium carbonate is used it is impossible to filter off the finely-divided oxide of iron.

—A. W.

*The Determination of Phosphorus in Steel.* C. B. Dudley and F. N. Pease. J. Amer. Chem. Soc. 16 [4], 217–224.

THE authors, needing to know with the utmost attainable accuracy the percentage of phosphorus in three samples of steel, made a comparison between various standard methods

with the aid of several chemists accustomed to steel analysis. Sample 1 was a boiler-plate steel containing about 0·15 per cent. C and less than 0·05 per cent. P; sample 2 was a fire steel with 0·5–0·6 per cent. C and 0·05–0·07 per cent. P; sample 3 was a reliable steel with 1·0–1·2 per cent. C and less than 0·01 per cent. P. Special care was taken in sampling. The results obtained for No. 1 varied from 0·035 per cent. to 0·042 per cent.; from No. 2, 0·015 per cent. to 0·026 per cent.; from No. 3, 0·019 per cent. to 0·033 per cent. For the purpose which the authors had in view, these variations were too great to be passed over, and an examination of the cause of discrepancy was accordingly instituted. It was seen that the acetate method tended to yield lower results than the molybdate process, and the following causes of loss were detected. When the process is worked in the usual manner the amount of iron in the ferric state used to precipitate the phosphorus as ferric phosphate is insufficient to carry the whole of the phosphorus down; the residue left on the filter, after dissolving through the ferric precipitate containing the phosphorus with hydrochloric acid, still gives a reaction with molybdate solution, and is therefore not free from phosphorus; the filtrate from the ammonium magnesium phosphate (citric acid being present) also gives evidence of the presence of phosphorus.

The fact that the molybdate method has a tendency contrary to that of the acetate process, prevents the use of the former as an absolute standard, and has led to the device of the following scheme:—10 grams of the metal are treated in the usual manner for the separation of phosphorus as ferric phosphate, but instead of oxidising only a small quantity of ferrous iron, at least 0·5 gram, is converted into the ferric state, and the basic acetate precipitation aided by the addition of a little ammonium acetate. The precipitate, containing all the phosphorus, is dissolved in moderately strong hydrochloric acid, the solution is evaporated to dryness, the residue treated with 40 cc. of strong nitric acid, and evaporation repeated to expel hydrochloric acid. The residue thus obtained is dissolved in 75 cc. of nitric acid (sp. gr. 1·13), the solution filtered, and precipitated with 75 cc. of molybdate solution, with the usual precautions. The precipitate is collected, well washed, dissolved in 2·5 cc. of strong ammonia, diluted with water, and washed until the filtrate measures about 100 cc. Sulphuretted hydrogen is then passed and the solution slightly acidulated with hydrochloric acid, by which treatment molybdenum sulphide is thrown down. The precipitate is filtered off, well washed with weak hydrochloric acid, and the solution evaporated nearly to dryness, diluted with a little weak hydrochloric acid, filtered if necessary, concentrated to 15 cc., and precipitated with magnesia solution and ammonia, and the precipitate collected in the ordinary way. This method tends to give results very slightly below the truth from the retention of phosphorus in the filtrate from the ammonia-magnesium phosphate, but it is preferable to either of the single processes. It is a modification of Riley's combination method, and has the advantage of eliminating arsenic at the point where the molybdenum sulphide is separated.

—B. B.

*The Volumetric Determination of Phosphorus in Steel.* C. B. Dudley and F. N. Pease. J. Amer. Chem. Soc. 16 [4], 224–230.

THE volumetric method, which consists essentially in reducing the phosphomolybdate precipitate by means of zinc and titrating the reduced solution by permanganate, is largely used in America, and its possible failings have now been studied by the authors. The following questions arise:—(1.) Is all the phosphorus collected in the molybdate precipitate? On this the authors cannot express a personal opinion, but quote Lawrence Smith to the effect that the concentration of the phosphorus in a small proportion of the iron by means of a preliminary basic acetate precipitation is desirable. (See preceding abstract.) (2.) Is the yellow precipitate of constant composition? This the authors answer in the negative, insisting on the need for observing standard conditions, and condemning the use of any ratio

expressing the composition of the yellow precipitate obtained under one set of conditions, for calculating the composition of a precipitate produced under different conditions. (3.) How shall the proper factor for use with permanganate of potash be obtained? The published ratios between molybdic acid and phosphorus vary from 100:1.54 to 100:1.90, and a similar ambiguity exists in the relation of the iron (used to standardise the permanganate) and the molybdic acid after reduction. The authors have endeavoured to settle this point by determining phosphorus in steel gravimetrically and volumetrically, and thus obtaining the ratio empirically. (See preceding abstract.) The values which they prefer are: iron to molybdic acid = 100:90.76, and molybdic acid to phosphorus = 100:1.90. (4.) If the conditions are made constant, will the results obtained be uniform and agree with each other? The authors consider that with identity of conditions the agreement of duplicates by the same chemist should be within 0.002 per cent., and of different chemists within 0.004 per cent.—B. B.

*The Determination of Phosphorus in Steel by Dudley's Method.* O. S. Doolittle and A. Eavenson. J. Amer. Chem. Soc. 1894, 4, 234—247.

The paper is mainly a criticism of that by Dudley (*vs.*), and deals with several points discussed by the latter.

*Ratio between phosphorus and molybdic acid in the yellow precipitate.*—The process chosen by Dudley of comparing gravimetric and volumetric results from the same steel, and thus obtaining an empirical ratio, was adopted. Four steels differing considerably in composition were used and gave ratios varying from 100:1.759 to 100:1.813, the value 100:90.76 being taken for the ratio between iron and molybdic acid. The authors therefore conclude that Dudley's ratio 100:1.90 is erroneous. A direct determination of the same ratio in yellow precipitate obtained from a solution of ferric nitrate containing phosphoric acid, was made by estimating the phosphorus in one weighed portion of a solution of the yellow precipitate, and the molybdic acid in another portion of the same solution. The method used for estimating the molybdic acid consisted in precipitation with lead acetate, the mixed precipitate of lead molybdate and lead phosphate being dried at 130° C., and the phosphate allowed for. The ratio between molybdic acid and phosphorus thus computed is 100:1.797. A repetition of the determination on yellow precipitate actually separated in the course of several steel analyses by Dudley's own method, gave the ratio 100:1.792, confirming the value usually accepted, viz., 100:1.794.

*Ratio between iron and molybdic acid.*—The authors found that the means adopted for reducing the molybdic acid previous to its titration with permanganate had a considerable influence upon the results. The common plan of passing the solution through the so-called "reductor" (a zinc-filled tower), gave results which fluctuated with the condition of the reducing material and the time occupied by the liquid in traversing the apparatus. Merely boiling with excess of zinc gave results appreciably lower than those obtained by the aid of the reductor. The ratio finally adopted by the authors between iron and molybdic acid is 100:89.16, instead of Emmerton's value 100:90.76.

*Effect of temperature on the precipitation of arsenic.*—The authors' results confirm those of Handy (*vs.*), in so far as the mechanical action of the phosphorus is concerned, in carrying down arsenic with the molybdate precipitate. Only when both phosphorus and arsenic are present in considerable amount is precipitation of the latter to be feared. A necessary precaution is to keep the temperature of the solution at the time of precipitation as low as is consistent with the complete separation of the phosphorus. The authors consider 32° C. a suitable limit.

—B. B.

*The Determination of Phosphorus in Steel in the Presence of Arsenic.* J. O. Handy. J. Amer. Chem. Soc. 16 [4], 231—234.

An objection to the molybdate method for the determination of phosphorus in steel is that arsenic may be simultaneously precipitated and reckoned as phosphorus. The author shows that when little or no phosphorus (*e.g.*, 0.002 per cent.) is present, arsenic is not precipitated even if present to the extent of 0.5 per cent. In the event of a larger quantity of phosphorus being determined, arsenic may precipitate, being apparently carried down mechanically, but can be eliminated by solution and re-precipitation. These data apply to the author's own method. (J. Anal. Appl. Chem. April 1892.)—B. B.

*Notes on the Determination of Nickel in Steel.* J. Westesson. J. Amer. Chem. Soc. 1894, 16, 110—112.

The presence of chlorides interfering with the electrolysis of the acetic solution after separation of the iron as basic acetate and necessitating the use of hydrogen sulphide to collect the nickel, the author dissolves 1 gm. of the sample in 1.16 sp. gr. sulphuric acid, to which 5 cc. of weak nitric acid is subsequently added; neutralisation with sodium carbonate and precipitation as basic acetate with the aid of sodium acetate are carried out in the usual way. The precipitation of the acetate is twice repeated, and the collected filtrates are evaporated to 400 cc., the addition at this stage of 10 cc. of strong ammonia, followed by boiling for a few minutes, is found to precipitate the manganese, which does not retain more than 1.5 per cent. of the total nickel present. The ammonia must be added to the hot solution in order to separate the manganese satisfactorily. The filtrate is then ready for electrolysis. Results are very concordant, and the whole analysis may be completed in eight hours, with the aid of eight good Grove's cells, or longer with a less powerful battery.—W. G. M.

*Determination of Nickel in Nickel Steel.* E. D. Campbell. J. Amer. Chem. Soc. 1894, 16, 96—102.

This method is intended to provide a rapid and accurate determination without precipitation of basic acetates or use of hydrogen sulphide. Dissolve 2.2222 grms. of the steel, boiling, in a 500-cc. graduated flask in 20 cc. nitric acid of 1.20 sp. gr., and 5 cc. hydrochloric acid of 1.21 sp. gr.; add 155 cc. sodium phosphate solution (200 grms. of crystallised  $\text{Na}_2\text{HPO}_4$  in 1,860 cc. of water); clear, if necessary, with a few drops of hydrochloric acid, add 25 cc. of 1.04 acetic acid, and then 100 cc. of sodium acetate solution (250 grms. crystallised salt in 820 cc. of water), shake, dilute to 502.5 cc., shake again, and allow to stand for 15 minutes. The ferric phosphate thus precipitated will be free from nickel, but may retain a little copper; it will occupy a volume equal to 2.5 cc. The liquid is passed through a dry filter into a dry beaker; 250 cc. is then withdrawn for further treatment, this being exactly half the solution after removal of the iron precipitate. Boil the 250 cc. and add 20 grms. potassium hydroxide dissolved in 40 cc. of water; boil for five minutes and then maintain nearly boiling until the precipitate has separated well; filter through an asbestos filter with the aid of the filter-pump, and wash. The precipitate contains every trace of copper, manganese, and nickel; it is now redissolved in 6 cc. of hot, strong hydrochloric acid mixed with 6 cc. of hot water, and the filter washed with the minimum of water. The solution and washings are caught in a flask, and should not exceed 50 cc.; to the liquid is added 15 grms. of granulated lead (of such size that it passes a sieve with 20, but remains on one with 40 meshes to the inch), which precipitates all the copper by exchange during a 10 minutes' intermittent agitation at 40° to 50° C. Filter through glass-wool, wash with a little water, evaporate the filtrate down to about 60 cc.; then add 10 cc. of the above-mentioned sodium phosphate solution and ammonia until a precipitate just forms, then add hydrochloric acid until it just redissolves, cool, transfer to a graduated vessel, add 5 cc. of ammonia (sp. gr. 0.90) and dilute to

111.1 cc. After shaking well and standing for 15 minutes, pass through a dry filter-paper, and reserve 100 cc. of the filtrate (equal to 1 gram of the steel) for determination of the nickel. The manganese, with lead from the copper precipitation, is thus separated. The nickel is then determined by electrolysis or volumetrically. For the electrolytic method, the 100 cc. of filtrate is transferred to a 200-cc. platinum dish, and there mixed with 25 cc. of ammonia (sp. gr. 0.90) and 50 cc. of water; after deposition, using a platinum cone as anode, the nickel is washed first with water and then with spirit, and dried 110°. The empty dish should be tared after the removal of the nickel deposit, which is effected by means of 6 cc. nitric acid of sp. gr. 1.2, and subsequent washing with spirit, followed by drying at 110°, in order to imitate as far as possible the conditions under which it was weighed with the nickel. For the volumetric process the 100 cc. of solution is just acidified with hydrochloric acid, and ammonia is then introduced until the deep blue colour of the ammonium nickel salt just disappears, after which an excess of 1 cc. is added, the whole is diluted to 200 cc., and 5 cc. of cupric ferrocyanide indication is run in, followed by standard potassium cyanide (12 grms. to the litre) until the purple colour changes to a clear pale, straw-yellow. After allowing for the cyanide used by the indicator, the nickel percentage is readily calculated. The cyanide solution must be standardised with nickel solution of known strength under similar conditions, as to bulk of solution and ammonia salts, to those obtaining in the analysis. The indicator is made by adding 500 cc. of water containing 2.5 grms. of potassium ferrocyanide, with constant stirring, to a solution formed by dissolving 2.5 grms. of copper sulphate in 25 cc. of water, adding to it ammonium oxalate until the precipitate first formed just redissolves, and then diluting to 500 cc. A precipitate sometimes forms on standing, but is so fine that, if the liquid be thoroughly shaken, it does not affect the accuracy of the estimation. The correction for the indicator is found by titrating 5 cc. to which 200 cc. of water, and six to eight drops of ammonia have been added; it should require about 0.2 cc. of the cyanide solution, of which 1 cc. = 0.0025 Ni. Duplicate results, right to within 0.05 per cent., may be obtained by the volumetric process within three hours of receiving the sample.

—W. G. M.

*Laboratory Notes.* J. S. de Benneville. J. Amer. Chem. Soc. 1894, **16**, 66—67.

In the analysis of ingot copper, the separation of many of the impurities by ammonia is often incomplete, and, moreover, the precipitate tends to pass through the filter: the author therefore dissolves 10 grms. of the metal in nitric acid, evaporates excess of acid, re-dissolves the copper in ammonia, and adds sufficient barium hydroxide to throw down all the minor constituents, the appearance of a scum (of  $\text{BaCO}_3$ ) indicating sufficiency of baryta. The precipitate, which separates well, is filtered and washed with dilute ammonia; it contains all the lead, bismuth, tin, iron, manganese, and antimony present, but not the whole of the arsenic or phosphorus. It may be treated by any known method of separation. The silver, zinc, and cadmium in the filtrate are precipitated by hydrogen sulphide, after decolorisation by potassium cyanide. If the solution of the 10 grms. of copper be diluted originally to 150 cc., but little of the copper ammonium salts separate out, and these dissolve readily in a little warm dilute ammonia, which does not affect the baryta precipitate. With 50 grms. diluted to 500 cc. considerable separation was noted.—W. G. M.

*Experiments on the Analysis of Pig-copper, Brasses, and Bronzes.* J. S. de Benneville. J. Amer. Chem. Soc. **16**, 133—140.

In this paper the author details experiments which he has made in working out his process for the analysis of pig-copper (*vide* preceding abstract). On treating an alloy of tin and copper with nitric acid a slightly excessive percentage of tin was found in all cases quoted, showing that

the metastannic acid was quite insoluble after 12 hours' digestion in the liquid obtained, either by simple dilution to 10 cc. after evaporation to pastiness, by dilution to 150 cc. with 6.92 per cent. nitric acid, by dilution to 10 cc. and with 5 grms. of added ammonium nitrate, by adding 6.52 ammonia, or by adding 5 grms. of ammonium nitrate and 6.52 ammonia. But if phosphorus is present in minute quantities it remains almost completely with the tin, when, however, the proportion of phosphorus to tin is high (*e.g.*, 25:7) much remains in solution, the ratio of  $\text{SnO}_2 \cdot \text{P}_2\text{O}_5$  in the residue averaging, in the case quoted, 1:4. In the case of arsenic, much may remain in solution even when an excess of tin is present. The phosphate and arsenate of tin are not completely decomposed even after a five hours' digestion with alkaline sulphide. When tin is thrown down from cuprous solutions by an excess of ammonia, the precipitate is always contaminated with much copper. Substituting antimony for tin in the experiments, it is found that the separation of antimony is not quite complete either from nitric acid or ammoniacal solution, and that the concentration of phosphorus in the residue is even more incomplete. Referring more directly to his own process, the author finds that while nickel, cobalt, zinc, cadmium, and silver are not at all precipitated, and tin, lead, and iron are completely precipitated either by ammonia or by a mixture of ammonia and barium hydroxide, the phosphorus, which is not separated by the former, is partially precipitated by the latter reagent, and the bismuth, manganese, and antimony which are incompletely thrown down by ammonia, are perfectly separated by the ammoniacal baryta. Arsenic is quantitatively precipitated only in concentrated solutions by the barium mixture, but not at all by ammonia alone. Finally the author finds that the manganese may be separated with sufficiently accurate results by precipitation with nitric acid and potassium chlorate, as in the similar method used for its determination in steel, and that without the removal of the copper from the solution, as had been proposed by Jones.—W. G. M.

*Note on Pemberton's Method of Phosphoric Acid Determination as compared with the Official Methods.* W. C. Day and A. P. Bryant. J. Amer. Chem. Soc. 1894, **16** [4], 282—283.

The authors find that the agreement between the two methods is as close as could be desired. Pemberton's statement that the time required for a single determination is 30—40 minutes from the measuring of the solution for titration, is entirely reasonable.—A. G. B.

*The Determination of Phosphoric Acid.* H. Pemberton, jun. J. Amer. Chem. Soc. 1894, **16** [4], 278—282.

In a previous paper (this Journal, 1894, 176) the author quoted some experiments which showed that 23.2 molecules of  $\text{Na}_2\text{O}$  are required to neutralise an amount of the yellow molybdate precipitate containing 1 mol.  $\text{P}_2\text{O}_5$ . New experiments have shown that this number should be 23 molecules, so that the standard acid for the process should be made by diluting 323.7 cc. of N-sulphuric acid to one litre, and not 326.5 cc., as previously stated.—A. G. B.

*The Chemical and Physical Examination of Portland Cement.* T. B. Stillman. J. Amer. Chem. Soc. **16** [3], 161.

See under IX., page 637.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*The Titration of Aniline and other Organic Bases with Methyl Orange.* G. Lange. Chem. Ind. **16**, 490.

ATTEN'S experiments on the titration of organic bases with methyl orange are stated by Lange to have been made by

him 10 years ago. The results, however, were found to be satisfactory in the case of quinoline only. The titration of para-quinidine showed only from 97 to 99 per cent., that of aniline from 90 to 94 per cent. of the quantity of base actually present. The bases were dissolved in 25 per cent. strong alcohol; solutions in stronger alcohol could not be titrated at all.—C. O. W.

*The Iodine Number of Rosin.* P. C. Mellbiny. J. Amer. Chem. Soc. 1894, 16, 56--57.

MILLS gives 112.7 as the bromine absorption of rosin, which is equivalent to an iodine absorption of 179, but this does not agree with the iodine numbers of Benedikt (115.7) and Williams (115.3 to 113.3). The author—working with different rosins, using 250 cc. silver a-say bottles with well-ground stoppers, and treating 0.3 gm. of the sample with 10 cc. of chloroform, and an iodine solution containing 25 grms. of iodine and 30 grms. of  $\text{HgCl}_2$  per litre, in a dark place—found an average iodine value of 155.5; but owing to intentional variations in the excess of iodine (equivalent to from 1.9 to 5.2 cc. of decinormal thio-sulphate solution) and in the time of absorption (2 to 52 hours) the actual numbers ranged from 126.7 to 172.6. The greater the excess of iodine and the longer the time of absorption, the higher was the reading. The variations are so great as to disqualify von Hubl's process for use with oils containing rosins.—W. G. M.

*A New Method of Analysing Fats and Resins.* P. C. Mellbiny. J. Amer. Chem. Soc. 1894, 16 [4], 275--278.

THE following process has been devised for determining the amount of bromine which oils and resins can absorb by addition ("bromine addition figure"), and at the same time the amount of bromine which replaces hydrogen ("bromine substitution figure"), in a given time. It depends upon the fact that bromine, in forming substitution products, liberates a molecule of hydrobromic acid for every atom of bromine which replaces hydrogen, whilst in forming additive compounds no hydrobromic acid is liberated.

From 0.25 to 1.00 gm. of the substance is dissolved in 10 cc. of carbon tetrachloride in a 500-cc. bottle. An excess of a solution of bromine in carbon tetrachloride ( $\frac{N}{3}$ ) is added, and the bottle kept in the dark for 18 hours. At the expiration of this period the bottle is placed in ice to form a partial vacuum by cooling the gaseous contents, and a piece of rubber-tubing is slipped over the neck so as to form a well around the stopper. This well is filled with water, and the stopper is carefully lifted, so that the water may be sucked into the bottle and absorb the hydrobromic acid present. When about 25 cc. of water have been added, the bottle is well shaken and 10--20 cc. of a 20 per cent. solution of potassium iodide and about 75 cc. more water are added. The liberated iodine is titrated with  $\frac{N}{10}$  sodium thio-sulphate. The contents of the bottle are transferred to a separator, the aqueous portion separated, and filtered through a cloth. A few drops of thio-sulphate are added to the aqueous solution if it be blue, and the liquid is titrated with  $\frac{N}{10}$  potassium hydroxide solution, methyl orange being used as an indicator. It is better to add an excess of the alkali and to titrate back.

The total bromine absorption per cent. is calculated from the difference between the bromine equivalent to the liberated iodine and the total bromine used. The bromine substitution figure is calculated from the amount of hydrobromic acid found by the titration, and returned as a percentage on the oil taken; twice this value subtracted from the total bromine absorption gives the bromine addition figure.

The following results are quoted:—

	Total Bromine Absorption in 18 Hours.	Bromine Addition Figure.	Bromine Substitution Figure.
W.G. rosin.....	212.70	0	106.35
E. rosin.....	206.50	0	103.25
Second rosin oil (a).....	116.20	0	58.10
" " (b).....	114.70	0	57.35
American raw linseed oil...	102.88	102.88	0
Same oil boiled.....	103.92	103.92	0
White salad cotton-seed oil..	65.54	64.26	0.64
Sperm oil.....	56.60	54.52	1.04

—A. G. B.

*Solubility Tests of Dark Mineral Lubricating Oils.* Holde. Mitt. K. Tech. Versuchsanst. 11 [5], 261--272.

IN a paper published in 1890 (311), the author described how certain dark mineral oils, when treated with petroleum spirit, gave a dark precipitate, soluble in benzene, which he identified as asphalt. In the present paper he further investigates the same subject. He had found that the specific gravity and boiling point of the petroleum spirit used as a solvent, greatly influenced the solubility of the asphalt, and great care had to be devoted to this point, as the previous experiments had shown that the asphalt, that would separate out from these oils, was in solution, or partly so, in the crude petroleum. A number of preliminary tests were therefore made of the solubility of the oils in question, in petroleum spirit. The results of these tests are given in tabular form in the paper.

They showed that the amount of deposit formed depended very largely on the specific gravity of the petroleum spirit used, and on the time the solution was allowed to stand. Oils which showed turbidity after standing for ten minutes, were frequently quite clear at first. Generally speaking, the more asphalt an oil contains the sooner the precipitate shows itself. All the oils experimented on in these tests were clearly soluble in the petroleum spirit used. It may be said that the larger the quantity of solvent added to the oil, the larger the volume of the deposited matter, and that filtering has no perceptible effect on this volume. The author considers that it may be generally assumed that the asphalt exists in a dissolved state in dark mineral oils rich in that substance, and that the dark particles observable in certain oils of this class are probably particles of solid paraffin coloured dark by the oil itself. The influence of the addition of asphalt on the physical properties of the oils, was also investigated, and it was found that it produces a certain thickening of the oil, an increase in the specific gravity, and a strong coloration. The effect of various quantities of asphalt on the viscosity is, however, but small. The addition of asphalt does not injuriously affect the behaviour of mineral lubricating oils at ordinary temperatures. When thin layers of asphalt-containing oils were subjected to a temperature of 100° C. for 10 hours the following effects were noticed. Oils containing but little asphalt, or none, remained liquid; those containing from 1.3 per cent. to 2.3 per cent. became sticky and thick; whilst oils containing 5 per cent. to 6 per cent. were converted into a thick resin-like mass. All these oils, however, remained liquid when the temperature was 50° C. instead of 100° C. For railway purposes, the percentage of asphalt must be small, or the oils are liable to solidify at low temperatures and to dry up at high ones. The author suggests the following conditions:—(1.) The oil should form a clear solution with benzol (which dissolves all the asphalt present). (2.) That petroleum spirit of a sp. gr. of 0.64 should not form a greater quantity

of deposit or precipitate with unfiltered than with filtered oil (thus the presence of suspended particles of asphalt is guarded against); and he is of the opinion that the testing of dark-coloured mineral oils for lubricating purposes, by examining the quantities of asphalt deposited by petroleum spirit, from small samples of both filtered and unfiltered oil, is desirable.—R. B. P.

*A Rapid and Accurate Method of Determining the Moisture and Oil in Linned Cakes and other Feeding-Stuffs.* A. P. Aitken. J. Amer. Chem. Soc. **16**, 114—122.

THE author believes that the discrepancies between different determinations of water in feeding-stuffs are mainly due to the low and comparatively irregular temperatures obtaining in the ordinary water-oven, and to the varying oxidation of oil in the sample. He therefore heats the material in a steam bath in a current of dry coal-gas (or hydrogen). The apparatus is shown in longitudinal and cross-section in the figure. It consists of a box 10 in.  $\times$  4 in.  $\times$  2 in., with a

small well below, and carrying a pair of horizontal tubes, such as are used for telescopes, running lengthwise, one above the other, but connected together at one end of each, which end is otherwise closed; at the top of the box is a  $\frac{3}{16}$ -in. hole (not shown) for the escape of steam. Connected with the box is an automatically-regulated supply-cistern B, so arranged that when the water level in the lower chamber sinks, air is drawn in through *v*, and the bottom of the tube *s* being uncovered, a bubble of air finds its way into the hermetically-sealed top of the upper reservoir, and displaces a corresponding

volume of water, which passes through the tube *a* into the lower reservoir. The sample to be examined (generally 1 gm.) is weighed into an aluminum boat *m*, which, with five similar boats, is placed on a tray *l* and introduced into the lower heating-tube of the steam bath. Coal gas, dried by passing over calcium chloride, is then passed through *d* into the upper tube, where it becomes heated, and then, after traversing the row of boats in the lower tube, is finally led off through *q* to the Bunsen burner *h*, and is there utilised for the generation of the steam required to heat the apparatus. The box is constructed of copper, but is jacketed throughout with  $\frac{1}{2}$  in. asbestos sheeting. The samples are cooled in desiccators and weighed, and may then be used for the determination of oil. The extraction of the oil is effected by ether, the sample being placed in a polished brass tube  $\frac{1}{2}$  in. in diameter and 4 in. in length, contracted at one end to a continuation tube  $\frac{1}{8}$  in. in diameter and 1 in. long. Before introducing the material into this tube, a disc of re-gauze, followed by a double tightly fitting wad of filter paper, should be introduced into the wide tube and pressed down to the contracted end; a second wad of paper only is finally placed above the sample. When oil-cake is being tested the gauze may be omitted. The extraction is effected with boiling ether with the aid of a specially constructed water-bath; this consists of a zinc box, somewhat shallower than the length of the extraction-tube, with a number of vertical copper tubes, running through from top to bottom and soldered in at both ends; each tube has a slight shoulder at the bottom, sufficient to catch and support the wide portion of one of the extraction-tubes, which must just fit into it. A gentle circulation of warm water is maintained in the box with the aid of an upper and a lower lateral tube soldered through one side of the bath. Below this box is a second water-jacketed vessel with a stop-cock at the bottom, and with perforations in its lid corresponding to the tubes in the upper box, through which pass the contracted portions of the extractors; a circulation of cold water is maintained in the jacket around the box, which thus serves to retain the ethereal solution of oil. In use, the tube containing the sample is dropped into one of the tube-sockets of the water-bath and is then filled with ether to within an inch of the top, and firmly corked. The pressure produced on boiling forces the ether through the material; it must then be renewed 10 (or even 20 times) until a drop yields no residue on evaporation. Finally the sample and wads are pushed out on to a watch-glass, the paper is removed, and the material dried at 100° and re-weighed. With very fine powders a half-turn screw-cap with a cork washer is substituted for the cork during extraction, in order to resist the pressure of vapour. The oil extracted is thus measured by loss of weight.—W. G. M.

*Determination of the Crystallisable Sugar in Beetroots.*

H. Pellet. J. Amer. Chem. Soc. 1894, **16** [4], 266—273.

A SUITABLE amount of the rasped pulp is weighed into a flask of a definite volume (26.048 grms., made up to 201.35 cc., are taken for the German instruments), and 5—7 cc. of lead subacetate (30 B.) and a little ether, to reduce the foam, are added; the flask is shaken and the volume made up. The solution is filtered and its rotatory power read. Sources of error are (1) the use of insufficient lead subacetate; and (2) the retention of air bubbles by the pulp, due to insufficient use of ether or insufficient agitation.

THE Lindeboom "sound," devised to extract cylinders of approximately the same weight from the roots, and Hanriot's machine for pulping the cylinders, are described as greatly expediting the work of a laboratory for the analysis of mother-beets. A "continuous tube" for polarimeter readings is used by the author; it consists of an ordinary tube with a side tube at each end; the sugar solution is displaced by water run through the tube, and the water is in its turn replaced by the next sugar solution, the disappearance of striae in the liquid being the indication of complete replacement.—A. G. B.

*Detection of Salicylic Acid in Food.* K. P. McElroy, J. Amer. Chem. Soc. 1894, 16 [3], 198-203.

Fitt. method at one time used by the author for the detection of salicylic acid in tinned vegetables, was carried out as follows:—The contents of the tin were triturated in a mortar, water and a little phosphoric acid being added, the mixture strained through a bag, and the filtrate distilled. The distillate was collected in fractions and tested with ferric chloride solution (5 mgrms. per cc.). As an illustration of the course of the volatilisation of salicylic acid in a current of steam, the following experiment may be quoted: 25 mgrms. of salicylic acid were dissolved in 250 cc. of water containing a little phosphoric acid and distilled, the distillate being collected in 25-cc. portions and the salicylic acid estimated colorimetrically. Fractions 1 and 2 gave a slight but distinct reaction; fraction 3 contained 0.3 mgrm. of salicylic acid; No. 4, 0.1 mgrm.; No. 5, 0.5 mgrm.; No. 6, 0.8 mgrm.; No. 7, 0.9 mgrm.; No. 8, 2.2 mgrm.; No. 9, 3.0 mgrms. The total quantity which distilled over was therefore 8.1 mgrms. A similar method is described by Ince for the examination of wine. 210 cc. of the wine are mixed with 10 cc. of dilute sulphuric acid and the mixture distilled, the distillate being collected in portions of 50 cc. The first portion is thrown away and the salicylic acid estimated colorimetrically in the next two. The result is multiplied by 8 and the product returned as the total content of salicylic acid. After the examination of various samples of tinned vegetables by his method described above, the author repeated the examination, taking the residual contents of the tins, which had, in the meantime, been dried and powdered finely enough to pass a 100-mesh sieve. Portions of this powder were made into a stiff dough with dilute sulphuric acid and extracted with ether. The ethereal extract was evaporated to dryness and the residue taken up with water and distilled. The distillate gave a stronger reaction than did the original trial by direct distillation, and in some cases salicylic acid was detected where it had previously been overlooked. This difference probably arose from the extraction of salicylic acid, in the second series of trials, from the solid part of the samples, while in the first only the juice was used. In some cases the quantity of salicylic acid found was so small that it appeared doubtful whether it could have been added as a preservative. This doubt is, however, resolved by a fact observed by Kolbe (J. Prakt. Chem. 1880, 21, 443, and 22, 112), who found that salicylic acid completely disappeared from water and wine contained in casks, whereas it remained in the same liquids kept in glass vessels. Four months' standing was enough to cause this disappearance in some cases. He proved that wood not only removed salicylic acid, but destroyed it, as the acid could not be recovered from test-cubes of wood immersed in solutions of salicylic acid. It is possible that the woody tissue of tinned vegetables may act similarly. The ordinary method of slaking out with ether is used by the author in the examination of beer and wine. The distillation process is cheaper and quicker than the method of extraction, and the reaction with ferric chloride is sharper, although less salicylic acid is obtained. The reason for this is that less impurity accompanies the distilled than the extracted acid.

The objection raised to the distillation process, that in the process of fermentation (e.g., of beer) certain phenol-like bodies are formed which interfere with the reaction for salicylic acid, would, if substantiated, apply equally to the extraction method. It has also been alleged that so-called "caramel malt" contains a substance capable of giving all the reactions characteristic of salicylic acid, with the exception of the reaction with Millon's reagent. Experiments made by the author on such malts gave negative results.

—B. B.

## ANALYTICAL AND SCIENTIFIC NOTES.

*Spontaneous Combustion of a Lamp-Shade.* A. Dupré, Times, May 23, 1894.

The writer states that on May 10th, a smell of burning being noticed in his house, search at length revealed the fact that a paper lamp-shade in one of the rooms had been

entirely consumed by fire. No damage was done, as no inflammable body was near the shade at the time. For two days prior to the accident the lamp had not been lighted, and there had been no fire in the room. Since morning, when the shade was intact, no one had even entered. The shade, made about a year ago from so-called crinkled tissue paper, consisted of one white and one yellow sheet, gathered into a bunch at the top, and spreading thence over the frame below. On examination, the yellow paper was found to be coloured by chromate of lead, and the author considers that the spontaneous ignition of the shade was due to this body, though he has not yet been able to reproduce the occurrence under experimental conditions. The dangerous paper is readily recognised by setting fire to a piece of it, and blowing out the flame. Should it behave like a piece of ignited touch-paper it is probably a chromate paper, and the writer considers it to be dangerous. Pale green papers, and possibly others, also contain chromate of lead.

—C. G. C.

*The Spontaneous Combustion of Lamp-Shades.* Chemical Trade Journal, 370, 404.

*Appropos* of the observations of Dr. Dupré on this question, Messrs. Crompton and Bros., paper-makers, of Elton, near Bury, Lancashire, write to the *Times*, stating that whilst they do not doubt that the writer of the letter is quite sincere in believing that the lamp-shade in his house fired spontaneously, they cannot believe such a thing to be possible. They state that since reading the letter referred to they have made numerous experiments with many of the various colours of the papers they make, and particularly with the chrome colours, and in no single instance could they get any one of them to fire spontaneously. They had the papers in question heated in a heating-chamber to nearly 200° F., with the result that in every case the papers when taken therefrom remained in their original uninjured condition, notwithstanding their being subjected to the heat named for several hours. They also saturated the papers with chromic acid and dried them, and even after this severe test failed to get them to fire spontaneously at the heat named, or under similar circumstances.

*The Odours of Benzoic Acids, with Remarks on other Odorous and Inodorous Bodies.* J. Passy, Comptes rend. 1894, 118, 481-482.

In a preceding note (Comptes rend. May 1, 1893) the author has shown that in proceeding down the series of normal fatty acids the odour regularly diminishes until, at the 14th term, it permanently vanishes, alike in the acid and in its aldehyde, alcohol, and ethereal salt derivatives. But with benzoic acid it is the acid alone which is inodorous in the pure state. Working with carefully purified benzoic acid prepared by four different methods, he finds that the crystalline acid is quite inodorous, but that if its solution in water or in alcohol be warmed, it at once evolves the characteristic benzylic smell of the other compounds. The same smell is recognisable if a 0.1 per cent. solution of benzoic acid containing 0.6 per cent. of sodium chloride at blood temperature be used as a nasal douche (Aronsohn's method). Inodorous bodies may thus be classed either as those which are always so, and those which under the conditions of the experiment have not passed into the "odorous condition." In its behaviour, benzoic acid is like vanillin, coumarin, and other perfumes, which only emit their characteristic odours at temperatures at which they are appreciably volatile.—W. G. M.

## New Books:

**SYSTEMATIC SURVEY OF THE ORGANIC COLOURING MATTERS.** By DR. G. SCHULTZ and P. JULIUS. Translated and edited, with extensive additions, by ARTHUR G. GREEN, F.I.C., F.C.S. London and New York: Macmillan and Co. 1894. Price 21s.

This is a translation, with very extensive additions, of the work of Messrs. Schultz and Julius, the appearance of which in the original German, was reported in this Journal, 1891, 662. It commences with the editor's preface, in which is set forth the fact that such a work as this would be of inestimable value not only to the technical chemist, but to the dyer, analyst, merchant, patent-agent, &c. For this country and America, the value of the work has been much enhanced by the addition by Mr. Green of about 50 new colours which have made their appearance since the publication of the German edition, and also by the references which have been given to British and American patents whenever these exist.

Page 1 to 57 is occupied by a concise and very instructive account of those coal-tar derivatives and compounds of the fatty series that are largely used in the coal-tar colour industry. This preliminary treatise forms the prelude to the tabular system of colouring matters, which extends from page 60 to page 189. The Translator and Editor's Appendix then follows with 21 new colours, and thereafter follow Tables for the Qualitative Analysis of the Artificial Colouring Matters, the first for Dyestuffs soluble in water and the second for those insoluble. The work closes with two Alphabetical Indexes, the first referring to the pages of the book, the second to the numbers indicating the position in the tables. The book is strongly bound in cloth and forms a volume of large 8vo size.

**JAHRES-RUNDSCHAU ÜBER DIE CHEMISCHE INDUSTRIE UND DEREN WIRTSCHAFTLICHE VERHÄLTNISSE FÜR DAS JAHR 1893, EIN ÜBERSICHTLICH GEORDNETER BERICHT ÜBER DIE FORTSCHRITTE DER CHEMISCHEN GROSS- UND KLEIN-INDUSTRIE, SO WIE ÜBER ANALYTISCHE METHODEN.** Unter Mitwirkung von Fachmännern. Herausgegeben von Dr. ADOLF BENDER. Vienna, Pest, and Leipzig: A. Hartleben's Verlag. London: H. Grevel and Co., 33, King Street, Covent Garden.

This work appears in four parts. Part I., containing 71 woodcuts, price 6s., and treating of Fuel; Metallurgy; Technology of Water; Manufacture of Inorganic Acids, Bases, and Salts; Earthenware; Cements and Artificial Stone; Glass; Manures; and the Apparatus and Machinery of Laboratories and Works. Part II., with 35 woodcuts, price 6s., and treating of Starch, Starch sugar, &c.; Beet-sugar, Cane-sugar, &c.; Milk, Butter, and Cheese; Flour, Bread, Preserves, Spices, &c.; Spirit Manufacture; Brewing, Wine; Sanitation, Disinfection, Medicaments, &c. Part III., with 24 woodcuts, price 3s., and treating of Organic Colouring Matters; Dyeing, Calico-printing, &c.; Tanning; Paper Manufacture. Part IV., with 26 woodcuts, price 3s., and dealing with Ethereal Oils and Resins; Fats and Mineral Oils; Lakes; Explosives; Photography; Adhesives and Cements. The four volumes or parts are bound in paper covers, and are of 8vo size, and each contains its own Table of Contents and Alphabetical Index. The whole collective work may also be obtained at the price of 18s.

**MICRO-ORGANISMS IN WATER.** Their Significance, Identification, and Removal, together with an account of the Bacteriological Methods employed in their Investigation. Specially designed for the use of those connected with the Sanitary Aspects of Water Supply. By PERCY FRANKLAND, Ph.D., F.R.S., and MRS. PERCY FRANKLAND. Longmans, Green and Co., London, and New York, 15, East 16th Street. 1894. Price 16s.

This is a large 8vo volume bound in cloth, and containing 320 pages of subject-matter, illustrated with 28 wood-engravings and 20 plates. The existing literature of the

Bacteriology of Water being both extensive and scattered, the authors have deemed it an urgent necessity to collate and condense this literature. This they have endeavoured to do in the present work, besides making numerous additions in the shape of the results of investigations of their own. A chapter has also been added on the comparatively novel subject of the Bactericidal Action of Light.

The leading themes treated of in the chapters of this work are as follows:—

I. The Sterilisation and the Preparation of Culture Media. II. The Staining and Microscopic Examination of Micro-organisms. III. The Examination of Water for Micro-organisms. IV. The Bacterial Contents of various Waters. V. The Purification of Water for Drinking Purposes. VI. The Multiplication of Micro-organisms. VII. The Detection of Pathogenic Bacteria in Water. VIII. The Vitality of Particular Pathogenic Bacteria in Different Waters. IX. The Action of Light on Micro-organisms in Water and Culture Media. X. An Appendix containing Tabular Descriptions of the various Micro-organisms found in Water. These comprise upwards of 200, and the descriptions thus given include the principal characters of all the micro-organisms, so far as the authors have been able to ascertain, as yet found in water.

**JAHRESBERICHT ÜBER DIE LEISTUNGEN DER CHEMISCHEN TECHNOLOGIE, MIT BESONDERER BERÜCKSICHTIGUNG DER GEWERBESTATISTIK FÜR DAS JAHR 1893.** Von Dr. FERDINAND FISCHER. Mit 200 Abbildungen. Leipzig: Verlag von Otto Wigand. London: H. Grevel and Co., 33, King Street, Covent Garden. Price, 21s.

This general report of the advance and condition of chemical technology for the year 1893, especially in the German Empire, has now appeared from the press. If the magnitude of that advance could receive any due measurement in accordance with the increase of the literature of the subject, the statement would not be without significance, that whereas the volume of Fischer's Jahresbericht issued for 1892, contained 1124 pages of text, the present issue for 1893 contains upwards of 1200 pages. In a work of this kind, one essentially of reference, the indexes must be of the most complete and searching character, and in this 1893 issue of the Jahresbericht we find these extending from page 1210 to 1272, i.e., over 62 pages. The index of authors fills 28, that of subject-matter 24, and the Index of German Patents 9 pages of the large 8vo volume. The text is illustrated with 200 engravings referring to plant and apparatus, and the treatment of the whole subject may be gathered from the following epitome of the sub-divisions of the same:—GROUP I. CHEMICAL TECHNOLOGY OF FUEL (pages 1 to 182). GROUP II. METALLURGY (pages 183 to 369). GROUP III. CHEMICAL MANUFACTURES: INORGANIC (pages 370 to 510). GROUP IV. CHEMICAL MANUFACTURES: ORGANIC (pages 511 to 677). GROUP V. GLASS, POTTERY, and EARTHENWARE, CEMENTS, ARTIFICIAL STONE (pages 677 to 765). GROUP VI. FOODSTUFFS (pages 766 to 973). GROUP VII. CHEMICAL TECHNOLOGY OF THE TEXTILE FIBRES (pages 974 to 1070). GROUP VIII. OTHER ORGANIC CHEMICAL INDUSTRIES (pages 1071 to 1175). GROUP IX. MECHANICAL AIDS AND APPARATUS FOR CHEMISTS (pages 1175 to 1299).

A comparison indicates that the literature of the following branches in the Jahresbericht for 1893 shows a marked increase over that in the Jahresbericht for 1892, which again indicates increased scientific and inventive activity in those branches:—Groups I., II., V., VII., and VIII., the increase of Group VIII. being by far the largest. Group VIII. includes Fats and Lubricants; Fat Acids, Soaps, &c.; Varnishes and Paints; India-rubber; Tanning, Glue, &c.; Manures, &c.; and the Preservation of Wood.

## Trade Report.

## TARIFF CHANGES AND CUSTOMS REGULATIONS.

## CANADIAN TARIFF CHANGES.

(From the Board of Trade Journal.)

A communication has been received at the Board of Trade enclosing copies of the tariff resolutions taking effect from the 27th March last. The following are some of the changes effected:—

Articles.	Rates of Duty.
<i>Alcohol, Spirits, &amp;c.</i>	
Spirituous or alcoholic liquors, distilled from any material, or containing or compounded from or with distilled spirits of any kind, and any mixture thereof with water, for every gallon thereof of the strength of proof, and when of a greater strength than that of proof, at the same rate as the increased quantity that there would be if the liquors were reduced to the strength of proof. When the liquors are of a less strength than that of proof, the duty shall be at a rate herein provided, but computed on a reduced quantity of the liquors in proportion to the lesser degree of strength; provided, however, that no reduction in quantity shall be computed or made on any liquors below the strength of 15 per cent. under proof, but all such liquors shall be computed as of the strength of 15 per cent. under proof as follows:—	
(a.) Ethylalcohol, or the substance commonly known as alcohol, hydrated oxide of ethyl or spirits of wine, gin of all kinds, N.E.S.; rum, whisky, and all spirituous or alcoholic liquors, N.O.P.; amyl alcohol or fusel oil, or any substance known as potato spirit or potato oil, methyl alcohol, wood alcohol, wood naphtha, pyroxylic spirit, or any substance known as wood spirit or methylated spirits, absinthe, arrack or palm spirit, brandy, including artificial brandy and imitations of brandy; cordials and liqueurs of all kinds, N.E.S.; mescal, pulque, rum, shrub, schiedam, and other schnapps; tafia, angostura, and similar alcoholic bitters or beverages.	Per gallon 2 dols. 12½ cts.
(b.) Spirits and strong waters of any kind, mixed with any ingredient or ingredients as being or known or designated as anodynes, elixirs, essences, extracts, lotions, tinctures, or medicines, N.E.S.	Per gallon 2 dols. 12½ cts. and 30° ad val.
(c.) Alcoholic perfumes and perfumed spirits, bay-rum, Cologne and lavender waters, hair, tooth, and skin washes, and other toilet preparations containing spirits of any kind, when in bottles or flasks weighing not more than four ounces each.	Per gallon 2 dols. 12½ cts. and 40° ad val.
When in bottles, flasks, or other packages weighing more than four ounces each.	Per gallon 2 dols. 12½ cts. and 30° ad val.
(d.) Nitrous ether, sweet spirits of nitre, and aromatic spirits of ammonia.	
<i>Animal Products.</i>	
Starch, including farina, corn starch, or flour, and all preparations having the qualities of starch; the weights of the package to be in all cases included in the weight for duty.	Per lb. 1½ cents.
Lard, hard compound, and similar substances, cotton-lene, and animal stearine of all kinds, N.E.S.	" 2 cents.
Tallow, stearic acid.	20° ad val.
Beeswax.	10° ad val.
Candles, N.E.S.	25° ad val.
Soap, N.E.S., pear-line and other soap powders, pumice, silver, and mineral soaps, sapolio, and like articles.	35° ad val.
Soap, common, or laundry, not perfumed.	Per lb. 1 cent.
Castile soap, mottled or white.	" 2 cents.
Glue and mucilage.	25° ad val.

## CANADIAN TARIFF CHANGES—cont.

Articles.	Rates of Duty.
Yeast cakes and baking powders, the weight of the package to be included in the weight for duty.	Per lb. 6 cents.
<i>Chemicals, Oils, and Paints.</i>	
Acid, acetic and pyroligneous, N.E.S., and vinegar, for any strength not exceeding the strength of proof.	Per gall. 15 cents.
For each degree of strength in excess of the strength of proof.	2 cents additional.
The strength of proof shall be held to be equal to 6 per cent. of absolute acid, and in all cases the strength shall be determined in such manner as is established by the Governor in Council.	
Acid, acetic, and pyroligneous of any strength, when imported by dyers, calico-printers, or manufacturers of acetates or colours, for exclusive use in dyeing or printing, or for the manufacture of such acetates or colours in their own factories under such regulations as are established by the Governor in Council.	25° ad val.
Glacial acetic acid or acetic acid exceeding the strength of proof, when imported by druggists and other than dyers, calico-printers, or manufacturers of vinegar or acetates or colours, to be used in their own factories for purposes of manufacture, other than as heretofore excepted from this provision, for the strength of proof.	Per gall. 15 cents.
For each degree of strength in excess of the strength of proof.	1 cent. additional.
Acid, muriatic and nitric, and all mixed acids.	20° ad val.
Acid, sulphuric.	Per lb. 1½ cent.
Sulphuric ether.	" 5 cents.
Acid, phosphate.	" 2 cents.
All medicinal, chemical, and pharmaceutical preparations, when compounded of more than one substance, including patent and proprietary preparations, tinctures, pills, powders, troches, lozenges, syrups, cordials, bitters, anodynes, tonics, plasters, liniments, salves, ointments, pastes, drops, waters, essences, and oils, not otherwise provided for:	
All liquids.	50° ad val.
All other.	25° ad val.
Provided that this item shall not be held to include drugs and preparations recognised by the British and the United States Pharmacopoeia as official.	
Cod-liver oil medicated.	20° ad val.
Oils, essential.	10° ad val.
Pomades, when imported in tins of not less than 10 lbs. each.	15° ad val.
Perfumery, including toilet preparations (non-alcoholic), viz.:—Hair oils, tooth and other powders and washes, pomatus, pastes, and all other perfumed preparations, N.O.P., used for the hair, mouth, or skin.	30° ad val.
Illuminating oils, composed wholly or in part of the products of petroleum, coal, shale, or lignite, costing more than 30 cents per gallon.	25° ad val.
Oils, coal, and kerosene distilled, purified, or refined; naphtha and petroleum, N.E.S., products of petroleum, not elsewhere specified.	Per imp. gallon 6 cents.
Lubricating oils, composed wholly or in part of petroleum, and costing less than 25 cents per imperial gallon.	Per imp. gallon 6 cents.
Crude petroleum, fuel and gas oil (other than naphtha, benzine, or gasoline), when imported by manufacturers other than oil refiners for use in their own factories, for fuel purposes and for the manufacture of gas.	Per gallon 3 cents.
Paraffin wax.	Per lb. 2 cents.
Paraffin wax candles.	" 4 cents.
British gum, dextrine, sizing cream, and enamel.	10° ad val.
Lubricating oils, N.E.S., and axle grease.	25° ad val.
Barrels containing petroleum or its products, or any mixture of which petroleum forms a part, when such contents are chargeable with a specific duty.	20 cents each.

CANADIAN TARIFF CHANGES—*cont.*

Articles.	Rates of Duty.
Linseed or flaxseed oil, raw or boiled, lamp oil, neat-foot oil, and sesame seed oil.	20 <sup>°</sup> <i>ad val.</i>
Olive oil prepared for salad purposes.	30 <sup>°</sup> <i>ad val.</i>
Vaseline and all similar preparations of petroleum for toilet, medicinal, or other purposes.	35 <sup>°</sup> <i>ad val.</i>
Blacking, shoe, and shoemakers' ink, and shoe harness, and leather dressing, and harness soap.	25 <sup>°</sup> <i>ad val.</i>
Ink for writing.	20 <sup>°</sup> <i>ad val.</i>
Blueing, laundry blueing of all kinds.	25 <sup>°</sup> <i>ad val.</i>
Dry white and red lead, orange mineral, and zinc white.	5 <sup>°</sup> <i>ad val.</i>
Ochres, ochrey earths, raw siennas, and colours, dry, N.E.S.	20 <sup>°</sup> <i>ad val.</i>
Oxides, dry fillers, fire proofs, umbers, and burnt siennas, N.E.S.	25 <sup>°</sup> <i>ad val.</i>
Paints and colours, rough stuff and fillers, N.E.S.	25 <sup>°</sup> <i>ad val.</i>
Paints and colours ground in spirits and all spirit varnishes and lacquers.	Per gallon 1 dol.
Turpentine, spirits of.	5 <sup>°</sup> <i>ad val.</i>
Varnishes, lacquers, japans, japan driers, liquid driers, and oil finish, N.E.S.	Per gall. 20 cents and 20 <sup>°</sup> <i>ad val.</i>
Paris green, dry.	10 <sup>°</sup> <i>ad val.</i>
Putty.	15 <sup>°</sup> <i>ad val.</i>

*Minerals.*

Asbestos in any form other than crude and all manufactures thereof.	25 <sup>°</sup> <i>ad val.</i>
Coal, bituminous.	Per ton of 2,000 lbs. 50 cents.
Coal dust.	20 <sup>°</sup> <i>ad val.</i>
Plumbago.	10 <sup>°</sup> <i>ad val.</i>
Plumbago, all manufactures of, N.E.S.	25 <sup>°</sup> <i>ad val.</i>
Electric light carbons or carbon points, not exceeding 12 inches in length.	Per 1,000, 2 dols. 50 cts. and in proportion for greater or less lengths.
Salt, fine, in bulk, and coarse salt, N.E.S.	Per 100 lbs., 5 cts.
Do. in bags, barrels, or other packages, the bags, barrels, or packages to bear the same duty as if imported empty.	Per 100 lbs., 7½ cts.

*Miscellaneous.*

Albumenised and other papers chemically prepared for photographers' use.	35 <sup>°</sup> <i>ad val.</i>
Glass carboys, empty or filled, and phials.	30 <sup>°</sup> <i>ad val.</i>
Common window glass.	20 <sup>°</sup> <i>ad val.</i>
Coloured glass and rolled plate.	25 <sup>°</sup> <i>ad val.</i>
Plate glass, not coloured, in panes of not more than 12 sq. ft.	Per sq. ft. 4 cents.
Plate glass, in panes not more than 30 sq. ft.	" 6 "
" " " 70 sq. ft.	" 8 "
" " " over 70 sq. ft.	" 9 "
When bevelled, in each case.	2 cents extra per sq. ft.
Silvered glass, N.E.S.	30 <sup>°</sup> <i>ad val.</i>
" " bevelled.	35 <sup>°</sup> <i>ad val.</i>
Stained glass windows.	30 <sup>°</sup> <i>ad val.</i>
All other glass manufactures.	20 <sup>°</sup> <i>ad val.</i>
Cement.	Per barrel 40 c.
Plaster of Paris, uncalcined.	15 <sup>°</sup> <i>ad val.</i>
" " calcined.	Per barrel of 300 lb. 10 c.
All manufactures of leather, N.E.S.	25 <sup>°</sup> <i>ad val.</i>
Celluloid in the rough.	10 <sup>°</sup> <i>ad val.</i>
Copper wire.	15 <sup>°</sup> <i>ad val.</i>
Zinc, N.E.S.	25 <sup>°</sup> <i>ad val.</i>

Phosphoric acid.	10 <sup>°</sup> <i>ad val.</i>
Lead.	Per 100 lb. one.
Chrome steel.	15 <sup>°</sup> <i>ad val.</i>
Nickel plated steel.	10 <sup>°</sup> <i>ad val.</i>

GENERAL TRADE NOTES.

SALT IN THE ISLE OF MAN.

According to Professor Boyd Dawkins, the prospects of the salt industry being established in the Isle of Man are sound, to say the least, and without being unduly sanguine, it may be added promising.

The fact of salt being worked at Preeval, and across the Irish Channel at Carrickfergus, caused geologists, not unnaturally, to wonder whether a submerged bed of salt connected the two districts. If that were so, it would by a natural sequence follow that salt should exist in the Isle of Man. At different times since 1886, Professor Dawkins has been endeavouring to ascertain if geological data could be got together to substantiate this conjecture. From the communication he has made this week to the Geological Society at Manchester, he seems to have been on the whole successful.

His geological investigations tend to show that North-Eastern Island, the north of the Isle of Man, and the English Lake District constitute one vast marine basin, from which the Triassic salt-bearing marls crop out at Barrow, the Isle of Man, and again at Carrickfergus, and are linked together by the deposits submerged in the Irish Sea. Borings have shown that the marls worked at Barrow and Carrickfergus are identical, and quite lately borings in search of coal rather than salt, made in the north of the Isle of Man have revealed such information touching the lay of the salt-bearing marls, as to give rise to the prospect of the salt industry being established in that island.

The bed of salt, as far as it has been investigated, is thinner than that which occurs at Dunerue, near Carrickfergus; but a boring at the Point of Ayre has resulted in the discovery of a bed over 31 ft. thick, the bore hole also intersecting a brine run 2 ft. 6 in. deep. As further confirmation of the possibilities of this industry being developed in the island, the fact may be cited that the sectional details revealed by the boring at the Point of Ayre, agree almost exactly with those which have been recorded about the saliferous marls of Dunerue; from which district, according to the latest statistics of the mineral production of the United Kingdom, close on 55,000 tons of rock salt are produced annually.—*Chemical Trade Journal*.

SUPPLIES OF CACUCHOUC IN BOLIVIA.

The French Chargé d'Affaires at La Paz learns from Santa Cruz that new clusters of *ficus elastica* have just been discovered on the rivers Verde, Tarvo, Itenes, San Martín, Paragua, and their tributaries. From Santa Cruz to Rio Paragua is a distance of 119 leagues, which may be covered in a fortnight. The road is flat and practicable for carts traversing numerous farms. Of this route 22 leagues is through desert country, and it is essential to mark out the ground from a point called Riaves as far as Rineonada, where the first acacias, so very rich in gum, are to be found. Rineonada (on the Rio Paragua) will be the depot for the leaves or sticks of *borrechu*. The route for exporting this product terminates at Puerto Suarez, situated at a distance of 165 leagues. This may be covered in 25 days, through a country almost level and practicable for carts, but with a scarcity of water and pasture land.—*Board of Trade Journal*.

ELEVENTH REPORT OF THE COMPTROLLER-GENERAL OF  
PATENTS, DESIGNS, AND TRADE MARKS; WITH  
APPENDICES FOR THE YEAR 1893. (C.—7386.)  
Price 2½d.

This annual report is issued by the Comptroller of the Patent Office in pursuance of the requirements of the 102nd section of the Patents, Designs, and Trade Marks Act, 1883 (45 & 47 Vict. c. 57).

The following statement shows the total number of applications for Patents, Designs, and Trade Marks, and amount of gross receipts and expenditure in each year, from 1884 to 1893 inclusive:—

Years.	Patents.	Designs.		Trade Marks.	Gross Receipts.	Gross Expenditure.
		Single.	Sets.			
1884	No. 17,110	No. 19,545	No. 238	No. 7,104	£ 103,827	£ 64,123
1885	16,101	20,388	337	8,026	88,509	77,739
1886	17,176	23,717	324	10,677	106,754	*109,567
1887	18,051	25,751	309	12,586	124,279	81,577
1888	19,103	25,923	316	13,315	119,623	83,924
1889	21,009	24,370	335	11,316	172,820	79,886
1890	21,507	22,255	318	10,258	192,006	83,240
1891	22,258	21,673	277	10,787	203,520	*103,180
1892	24,169	19,269	258	9,101	199,859	*96,822
1893	25,120	19,174	306	8,675	174,878	*95,103

\* Including expenditure on account of new offices and buildings.  
—*Ibid.*

#### PHOSPHATE AND ASBESTOS MINING IN CANADA.

The French Consul in Quebec, in a recent report to his Government, says that for the last two years the most important of the mining products of the province—phosphates and asbestos—which used to be exported in vast quantities, have shown a considerable falling off in the quantity produced, so much so that production has almost completely ceased. It is expected that this check in the development of a very important industry will only be of a temporary nature, and that, fresh demands arising, the production will resume its upward course that until recently it has followed for so many years.

Phosphates are found in large quantities in the province of Quebec. Their first working only dates back to 20 years ago, and the production, which was about 4,000 tons in 1878, attained in recent years an average of 25,000 tons annually. The new phosphate beds discovered in Florida, the competition with which has brought about a considerable fall in prices, has rendered the working of Canadian phosphate comparatively unremunerative. The rates quoted on the English market, which were about 5*l.* per ton in 1889, fell to 3*l.*, and thus brought about a complete stoppage in the production in 1893. Canadian phosphates, which are remarkable for their richness, are found under the form of apatite in crystalline masses of a red or green colour. According to official statistical returns the quantity of phosphates exported from Quebec in 1880–81 amounted to 15,701 tons; in 1884–85, 18,984 tons; in 1890–91, to 25,257 tons; and in 1891–92, to 17,243 tons.

Equally with phosphates, asbestos, which has been worked in Quebec since 1878, has given rise to an industry which was rapidly developed to such a point that the production, at first only amounting to a few hundred tons, exceeded 8,000 tons in 1890 and 10,000 in 1891.

Asbestos is a product peculiar to the province of Quebec, which, with Italy, are the only places which supply this article to commerce. Numerous and fresh uses for this material having been discovered of recent years, a peculiar phenomenon was observable; this was that in spite of the considerable increase in the production the prices rose by about 80 dollars a ton, until they attained a rate of 250 dollars

in 1890. Since the latter date, however, prices have again fallen. Asbestos is principally used in various ways in connection with steam machinery and electric lighting. With it are made felts, tissues, packing paper, cements, bricks, &c. This product, which has received the name of chrysotile, a form or serpentine, is found in certain portions of the serpentine rocks of the Eastern Township of Quebec, as well as in some parts of Ottawa county, Quebec. The mining is practically confined to two sections, one at Thetford and the other at Black Lake, the two sections being about four miles apart. The mineral found in these districts is of the very highest quality, while elsewhere there are deposits of a lower grade, which, while not suitable for millboard and steam-packing, answer admirably for cements, paints, &c.—*Ibid.*

#### THE NORWEGIAN WOOD-PULP INDUSTRY.

According to the *Bulletin du Musée Commercial*, the year 1893 was a very favourable one in Norway for manufacturers of wood-pulp, the prices having on the average been four kroner (4*s.* 5½*d.*) higher for wet pulp, and eight kroner (8*s.* 10½*d.*) higher for dry than they were in the preceding year.

Purchasers hastened to place their orders, and at the commencement of the year the quantities sold amounted to 130,000 tons. The demand having again increased, the wood-pulp syndicate realised that the reduction of the production to the extent of 33½ per cent., which was primarily fixed upon, was too great, and at a meeting which was held in May the maximum reduction was fixed at 23½ per cent., but in spite of this prices continued to rise. Towards the end of the year small quantities which were available were sold at 55 kroner (3*l.* 1*s.* 1½*d.*) and 100 kroner (5*l.* 11*s.* 1½*d.*) per ton respectively for pulp wet and dry.

For the current year the greater part of the production is already sold at remunerative prices. The improvement which has manifested itself in the Norwegian wood-pulp industry has led to the very considerable extension of the factories already existing, and to the construction of new works in Sweden and Norway.

The home consumption has remained almost stationary; in England the consumption has increased, and also in France. As regards Germany, this country imported, in 1893, 10,000 tons of Norwegian wood-pulp more than in 1892, but this increase was in great measure due to the dryness of the season last year. At the present time there are 59 wood-pulp factories in Norway; of this number one is engaged in the manufacture of casks, three manufacture cardboard, and ten paper.

The quantity of wood-pulp exported from Norwegian ports, that is to say, the Norwegian product, and a certain proportion of Swedish pulp, amounted in 1893 to 230,000 tons, as compared with 215,000 tons in 1892 and 207,000 tons in 1890. The above observations and figures all relate to mechanical wood-pulp.

As regards chemical wood-pulp, the increase in the demand created in 1892, by reason of the restrictions effected in the rag trade continued in 1893, and the results of that year have been equally favourable to that industry. The prices in 1893 of dry chemical pulp quoted by the Norwegian manufacturers were as follows:—First-class dry sulphite, from 200 to 210 kroner (11*l.* 2*s.* 2½*d.* to 11*l.* 13*s.* 4*d.*); second-class from 185 to 195 kroner (10*l.* 5*s.* 6½*d.* to 10*l.* 16*s.* 8*d.*) per ton. First-class sulphate pulp was quoted at from 180 to 190 kroner (10*l.* to 10*l.* 11*s.* 1½*d.*) and second class from 170 to 180 kroner (9*l.* 8*s.* 10½*d.* to 10*l.*). It is stated that these prices are with difficulty obtained, and the numerous factories recently erected or projected in Norway, Sweden, and America, do not appear to have a very brilliant future before them. In all probability the prices of pulp will, it is said, fall, while those of the raw material will rise.—*Ibid.*

#### THE POSITION OF COLLODION COTTON.

The following letter has been issued from the Home Office:—

April 25, 1894.

Since the Explosives Act, 1875, came into force, the question has more than once been raised as to the position

of collodion cotton, or, as it is sometimes called, soluble gun-cotton; and, as you are probably aware, we have until recently held that such material need not be ranked as an explosive.

Further researches on the subject of the material have, however, disclosed the fact that its solubility may in some cases be associated with a certain explosibility, and under these circumstances it appears to us that soluble gun-cotton does, as a matter of fact, properly fall within the category of explosive as defined by the Explosives Act, 1875, and the Orders thereunder, except when its condition is such as to deprive it of its explosive properties, viz., when it is—

- (a) In solution in alcohol or ether, or
- (b) wet, or
- (c) saturated with methylated spirit and contained in air tight cases.

We have been in communication with the Customs on this subject, and we understand that they are issuing instructions to their officers to that effect. Of course this decision affects the manufacture, storage, and transport of soluble cotton, which does not fall within the exemptions specified above; of course, also, when soluble gun-cotton is intended for use, itself, as an explosive (not merely as an ingredient of an explosive), it necessarily falls within the definition of an explosive, in virtue of section 3. of the Act, irrespective of the condition in which it may exist.

#### SOUTH AFRICAN SUGAR INDUSTRY.

*Deutsches Handels. Archiv*, 1894, 105.

The sugar industry of Natal makes no attempt to compete with the world's market; its scope does not extend beyond the limit of the South African market. The sale of sugar within the colony itself is protected by a tax, which, for refined sugar, amounts to 1*d.* per lb., and for raw sugar to 3*s.* 6*d.* per centner; whilst its sale beyond the limits of the neighbouring States is subject to the taxes there existent. In the territories of the South African Zollverein (Cape Colony, Orange Free State, Basutoland, British Bechuanaland) and in the protectorate of Bechuanaland, these taxes amount to 6*s.* 3*d.* per 100 lb. for both refined and raw sugar. On raw sugar re-exported into those territories of South Africa not belonging to the Zollverein, a reimbursement of 3*s.* per 100 lb. is allowed. An abatement of 5 per cent. is allowed in Cape Colony on all imported sugar for the manufacture of preserved fruits and confectionery. The tax on sugar, whether refined or raw, in the South African Republic is 3*s.* 6*d.* per 100 lb. The effect of heavy taxes on Natal sugar sold in the neighbouring States is that all those interested in the Natal sugar industry are zealous supporters of the extension of the Zollverein.

The average annual production of sugar in Natal during the last 10 years is assessed at 12,000 tons. According to the "*Blaubuch*" it amounted to—

	Tons.
In the financial year 1890—91.....	11,640
" " 1891—92.....	26,319.25

the values of which for the two periods were 25*l.* 5*s.* and 23*l.* respectively per ton. Statistics regarding the amount of sugar exported are only at hand in the case of that exported by sea. The average amount during the last five years was:—Raw sugar, 5,234 tons; molasses, 222 tons. The Customs authorities in Natal divide everything into these two categories, whereas the Customs authorities in Cape Colony differentiate the imported sugar from Natal between raw sugar, to which the chief portion corresponds; also between refined sugar and "crystals." The distinction between raw and refined sugar has only, at present, a significance for the tax administrators of Cape Colony in so far as it touches the transport to territories without the Zollverein. Refined sugar includes only loaf- and cube-sugar. The raw sugar of Natal may be used for consumption, and, as a matter of fact, is exclusively used in Natal. The quantity of imported foreign sugar, as well as that transported into the interior, is very small in comparison

with the quantity of the home product. The average market price of sugar was—

	Per lb.
In the financial year 1890—91.....	3 <i>d.</i>
" " 1891—92.....	3 <i>d.</i>

The sugar landed in the ports of Cape Colony during the last five years was, besides a small quantity of molasses, as follows:—

	Tons.	£
Raw sugar.....	15,158	leaving a value of 226,000
Refined sugar and crystals.....	1,555	29,000

The quantity of imported sugar during late years is steady and has not inconsiderably increased. Besides the above mentioned quantities of sugar, however, there was landed at the ports of Cape Colony during the five years 1888—1892 an average annual quantity amounting to 3,120 tons for transportation to the territories beyond the Zollverein. The amount seems steadily increasing, and reached in the last year of the period named 15,710 tons.

In view of the steadily-increasing consumption of sugar in South Africa, a syndicate has been formed and a limited company floated with the object of constructing a beet-root sugar factory in the district of Swellendam, east of Cape Town. The prospectus was circulated in September 1893. At first, the whole of the required capital, amounting to 39,000*l.*, could not be got together, but the remaining portion was subsequently subscribed in London.

The contract for the furnishing of the factory and the accessory machinery has been given to a German firm. The value of this contract is said to be about 20,000*l.*

—A. R. L.

#### SCANDINAVIA AS A SOURCE OF IRON ORE SUPPLY.

*J. Head. Iron and Steel Institute, Spring Meeting, 1894.*

Although pigs and bars have long been known as Scandinavian products, iron ore has not been regarded as an important article of export until comparatively recent time. In 1870, 9,485 tons were exported from Sweden, whilst in 1887, 41,765 tons was the amount. On the latter quantity only 657 tons came to the United Kingdom. In the same year Norway supplied 2,485 tons. The total quantity of ore received in 1887 from Scandinavia by the British Iron Trade therefore was only about 3,000 tons. In 1888 the figure 657 rose to 62,672 tons, this increase being due to new railway and steamship companies, formed chiefly with English capital. Most of the ore smelted in England gave disappointing results, the pig-iron produced containing from 0.3 to 0.6 per cent. of phosphorus, which of course rendered it unfit for acid steel-making. As there was very little demand for such pig-iron the allied companies had to discontinue operations. As a result the imports of Swedish ore into the United Kingdom fell to 15,427 tons in 1889, and to 3,108 tons in 1891.

The English companies had made the mistake of mixing, as a rule, the products of the various quarries, thus producing an average quality which was neither pure enough for acid nor phosphoric enough for basic purposes. A Swedish company was formed which, profiting by the experience of their predecessors, took care to keep separate the products of the various workings, and to grade them according to the contained phosphorus.

They established four grades, A, B, C, and D, the first containing about 69 per cent. of iron and 0.01 per cent. of phosphorus intended for the acid process, and the last containing about 65 per cent. of iron and 1 to 2 per cent. of phosphorus intended for the basic process, with intermediate classifications for the other grades. The yield of the 131 quarries thus carefully assorted was found to be 20 per cent. of grades A and B, and 80 per cent. of the lower grades. The effect of these improved arrangements was soon apparent, and the figures rose from the above quantity in 1891, to 13,722 in 1892, and 35,901 tons in 1893. The material being almost entirely of the A quality. The Continent apparently has taken more advantage of this new source of iron ore supply, as the figures have risen from 117,530 tons in 1888 to 447,931 tons in 1893, this quantity

being received mostly by Germany and Austria. The basic process being largely employed on the Continent, the material sent there was mainly of the lower grades, which would hardly pay to send to England.

The author then enters into the question of the prices of transit, and says there is little prospect of Swedish ore of any kind being delivered in Middlesbrough, even through the contemplated new railway to Væsterås on the Norwegian coast, at less than 12s. per ton, a price which excludes the lower-grade ores. It is obvious that a reduction of this figure would be effected by the discovery of iron ore deposits nearer to this port, if such could be made.

It would appear that Titanic acid in variable proportions is a common constituent of Scandinavian ores. When used alone they have been found extremely difficult to smelt, owing to the Titanic acid.

If smelted, however, with poorer ores, especially such as contain alumina, the refractory nature seems to disappear. Titanic acid does not convey any impurity to the pig, but it seems to communicate to the iron unusual toughness, and causes sulphur and phosphorus to go into the slag, requiring also an increased coal consumption in the furnaces. The advisability of encouraging Scandinavia as another ore supply for Great Britain is advocated by the author.

—A. W.

#### THE WORLD'S PRODUCTION OF NOBLE METALS.

*Chem. Ind.* 16, 485.

The production of platinum is increasing in the United States. The nickel ore from Copper Cliff, near Sudbury, contains 0.20 per cent. of platinum, and similar ores have been observed at Denison (Ontario), containing from traces to 0.53 per cent. of platinum. A recent discovery of platinum ores on the river Tulamee, in British Columbia, appears to be of even greater importance. The production of nickel in America amounted in 1882 to 281,600 lb., which is about equal to the production of Sweden and Norway. Some of the occurrences of nickel ore in Arkansas, Colorado, Connecticut, Iowa, Massachusetts, Missouri, Nevada, North Carolina, and Oregon, are said to be very promising. The prospects of the nickel mines of New Caledonia have been considerably improved since the construction of roads to the mines. The exports of nickel ore, which in 1885 amounted to 19,700 tons only, subsequently rose to 35,000 tons in 1891. The Sudbury mines exported about 72,300 tons in 1892. The total production of the world amounts now to 10,307,000 pounds of nickel, the price of which has fallen as the production increased. Of late years nickel has attained considerable importance in the manufacture of very hard alloys of nickel and iron. This nickel steel is largely employed for the manufacture of armour plates and for ships' engines. An alloy of 20 parts of nickel with 80 parts of copper is used as a casing for the bullets of the new small calibre. The world's production of silver amounted to 2,592,000 kilos. in 1881, and remained stationary until about 1887. Since then the production of silver has increased at an enormous rate on account of the discovery of the rich deposits in the Sierra Mojada, Colorado, and Montana, and rose to 4,479,000 kilos. in 1891, and 5,935,000 kilos. in 1892. On the other hand, the production of gold, which in 1881 amounted to 158,000 kilos., remained stationary until 1888. Then it increased through the opening of the South African goldfields to 192,000 kilos. in 1892. Part of this increase is, however, due to the extraction of gold from American silver ores. The silver output of America alone amounted to 692,000 kilos. in 1872, 1,240,000 kilos. in 1885, and 2,018,000 kilos. in 1892. The relation between the price of gold and silver was as 1:15.56 in 1870, 1:18 in 1886, and 1:22 in 1890, and in spite of the Sherman bill came to 1:23.73 in 1893.—C. O. W.

#### ALCOHOL IN GERMANY.

Official figures relating to the spirit industry of the German Empire have just been published. They show that 60,025 alcohol-distilleries were at work in the Empire last year, against 59,789 in 1892. More than one-third (22,929) of these are found in the grape-growing provinces of Alsace-Lorraine; 19,577 in Baden; 6,508 in Württemberg; 4,667

in Bavaria; and only 6,108 in Prussia. The great majority of the distilleries (47,385) are small ones, using fruit, brewery-refuse, &c., as raw material. Only 27 works distil molasses—a branch of industry which appears to be dying out, as in 1891—92 there were only 39 molasses-using distilleries at work. Farinaceous substances (potatoes and grain) are used by 12,613 works. Prussia, although possessing the smallest number of works, has by far the largest, her share of the total alcohol-output of 3,028,920 hectolitres (of about 22 gallons) absolute alcohol being 2,449,626 litres. The largest Prussian factory produced over 10,000 hectolitres. The consumption of absolute alcohol in Germany for drinking purposes in 1892—93 was 2,254,919 hectolitres, or 4.5 litres per head of the population (= about 1 gallon). In 1891—92 it was 4.4 litres. The quantity used for industrial purposes was 60,670 hectolitres, against 551,300 the year before, of which 115,026 were used in vinegar-manufacture, and 315,254 were denaturalised. The total exports of German alcohol were only 111,447 hectolitres absolute. The gross revenue from the spirit tax was 111,435,216 m. in 1892—93 against 134,185,046 m. the year before. The following quantities of raw material were used for distilling:—Potatoes, 2,105,890 tons (1891—92, 1,334,602 tons); corn, 338,370 tons (1891—92, 490,420 tons); molasses, 37,453 tons (1891—92, 94,924 tons); stone-fruit, 252,900 hectolitres (1891—92, 306,031 hectolitres); wine-berries, 231,467 hectolitres (1891—92, 168,229 hectolitres); malt residue, 195,338 hectolitres (1891—92, 208,875 hectolitres); fruit (various), 64,006 hectolitres (1891—92, 89,434 hectolitres); liquid wine-berries, 30,252 hectolitres (1891—92, 18,211 hectolitres); pressing-residue from grapes, 29,517 hectolitres; (1891—92, 44,096 hectolitres); grape-wine, 15,743 hectolitres (1891—92, 11,301 hectolitres).—*Chemist and Druggist*.

#### BENGAL SALTPETRE.

In the Presidency of Bengal, saltpetre is manufactured in the Patna and Bhagalpore divisions and in the city of Calcutta and its suburbs. Crude saltpetre, however, is not manufactured in or near Calcutta, operations being confined there to the refining of the article imported from up-country. The control of the saltpetre refineries in Bengal is vested in the Commissioner of Northern India Salt Revenue and his subordinates. A large quantity of edible salt is obtained in the process of refining saltpetre, and under the existing rules the owners have the option either of destroying it or removing it from the refineries on payment of full duty. A market has, however, been created for this species of salt, and large quantities of it are now exported to Burdwan and other places. The fee for a licence for manufacturing and refining saltpetre, including the extraction of salt therefrom, is Rs. 50, and that for the manufacture of saltpetre, sulphate of soda (*khari*), either by solar heat in evaporating pans or by artificial heat, and of any other substance included under the term of "saltpetre" as defined in section 3 of the Salt Act of 1882, is 4 annas. Besides the saltpetre brought from the Patna and Bhagalpore divisions, a considerable quantity comes down from the North-West Provinces and the Punjab. The bulk of the saltpetre brought to Calcutta is exported to the United Kingdom, the United States of America, Mauritius, and China. The total exports in 1892—93 amounted to 438,408 cwt., valued at Rs. 43,36,588.—*Ibid*.

#### THE MANUFACTURE OF CITRIC AND TARTARIC ACIDS IN SICILY.

Our Sicilian correspondent writes:—"The Italian Government being desirous of encouraging the preparation in Sicily of citric and tartaric acids, especially the former, has issued a decree offering prizes to persons who shall open factories for the preparation of these acids in Sicily. The first prize is to be one of 500*l.*, the second of 350*l.*, and the third of 175*l.* sterling, in addition to which small bonuses will be given to the managers of works. To obtain the first prize both citric and tartaric acid must be made, the former in a quantity of at least  $\frac{1}{2}$  ton a day. Preference will be given in the competition to those firms making their own sulphuric acid, for the production of both citric and tartaric

acids. It is also laid down as a guide to the jury that they are to give the preference to those making the best use of subsidiary products, and those using vacuum apparatus, or apparatus made of enamelled iron or porcelain for evaporation. Applications for the prizes must be made on Italian stamped paper not later than December 31, 1893, and the works must be in operation not later than February, 1896, in which year the prizes will be distributed by the Minister of Agriculture. The competition appears to be open to foreigners. There are already two works in operation in the island.—*Ibid.*

#### THE ITALIAN TRADE IN TARTARIC MATERIALS.

Tartaric materials form one of the chief items of export from the southern provinces of Italy; the season commences in October, and official statistical reports for the year are generally given from that month to September of the following year. In 1891—92 the total export amounted to 9,814 tons, valued at 425,240*l.*; while in 1892—93, 9,881 tons, valued at 337,275*l.*, were shipped. The great difference

in value arises from the depreciation this article has undergone in consequence of the large stocks accumulated everywhere through the excellent grape harvests of the last two years. The tartaric materials exported during the last two years were composed as follows:—

		Half Refined Tartar.	Ammonium Argols.	Crude Argols.
1891—92.....	Tons	1,542	3,124	2,470
" .....	"	98,280	14,100	101,640
1892—93.....	Tons	1,317	2,959	2,801
" .....	"	72,435	133,155	98,025

More than one half of these products, especially "argols," is shipped to the United States; the remainder is taken by Great Britain, France, Germany, and Austria in about equal shares.—*Ibid.*

Tin..... Cwt.	67,210	64,975	398,879	224,113
Zinc..... Tons	5,510	3,766	100,162	59,890
Other articles ... Value £	..	..	144,382	123,218
Total value of metals	..	..	1,943,602	1,503,982

## IMPORTS OF OILS FOR MONTH ENDING 31ST MAY.

Articles.	Quantities.		Values.	
	1893.	1894.	1893.	1894.
			£	£
Cocoa-nut..... Cwt.	12,948	19,453	18,461	22,644
Olive .....	2,439	1,805	84,305	65,922
Palm .....	89,411	114,093	199,238	146,917
Petroleum .....	12,037,764	12,036,671	190,253	157,099
Seed .....	2,127	2,400	55,728	55,282
Train, &c..... Tons	1,119	1,927	20,892	39,549
Turpentine .....	4,045	791	5,157	799
Other articles .. Value £	..	..	92,866	95,896
Total value of oils...	..	..	574,910	544,970

## IMPORTS OF RAW MATERIAL FOR NON-TEXTILE INDUSTRIES FOR MONTH ENDING 31ST MAY.

Articles.	Quantities.		Values.	
	1893.	1894.	1893.	1894.
			£	£
Bark, Peruvian .. Cwt.	7,592	7,896	15,931	14,949
Bristles..... Lb.	351,522	250,986	57,345	34,823
Caoutchouc..... Cwt.	39,814	32,335	355,949	353,909
Gum:—				
Arabic.....	8,023	3,644	17,095	12,792
Lac, &c.....	14,944	14,778	73,798	89,842
Gutta-percha ....	4,929	4,185	32,399	43,376
Hides, raw:—				
Dry.....	44,485	36,619	114,493	85,617
Wet.....	41,967	44,138	99,985	94,741
Ivory.....	624	496	36,356	21,884
Manure:—				
Guano..... Tons	2,343	1,343	12,925	8,782
Bones.....	5,969	7,495	25,494	35,383
Nitrate of soda... ..	22,253	14,264	294,842	137,397
Phosphate of lime ..	27,976	38,905	48,526	71,864
Paraffin..... Cwt.	89,833	59,769	92,069	53,440
Linen rags..... Tons	1,123	1,677	9,897	13,830
Esparto.....	17,166	15,256	88,188	96,590
Pulp of wood ....	21,973	22,615	115,582	112,881
Rosin..... Cwt.	156,554	151,556	58,826	34,495
Tallow and stearin ..	169,908	117,912	228,952	152,534
Tar..... Barrels	5,810	6,599	3,124	3,697
Wood:—				
Hewn .....	225,687	207,591	452,582	355,645
Sawn .....	399,939	395,022	694,401	889,058
Staves .....	8,827	9,855	52,829	45,472
Mahogany .....	4,104	3,901	55,796	32,573
Other articles.... Value £	..	..	97,999	895,008
Total value .....	..	..	3,825,123	3,642,386

Besides the above, drugs to the value of 72,200<sup>l</sup>. were imported, as against 72,726<sup>l</sup>. in May 1893.

IMPORTS OF CHEMICALS AND DYESTUFFS FOR MONTH  
ENDING 31ST MAY.

Articles.	Quantities.		Values.	
	1893.	1894.	1893.	1894.
Alkali..... Cwt.	8,358	8,558	£ 7,987	£ 8,185
Bark (tanners', &c.) ..	34,300	26,917	13,111	9,449
Brimstone..... "	33,591	49,052	8,549	11,728
Chemicals..... Value £	..	..	116,292	132,673
Cochineal ..... Cwt.	77	197	723	1,918
Cutch and gambier Tons	2,441	2,517	52,274	61,656
Dyes:—				
Aniline..... Value £	..	..	13,496	17,354
Alizarin ..... "	..	..	25,300	25,838
Other ..... "	..	..	2,073	2,909
Indigo ..... Cwt.	2,042	1,914	34,743	33,954
Nitrate of potash . "	26,589	15,882	22,318	14,785
Valonia ..... Tons	1,668	1,311	22,131	16,717
Other articles... Value £	..	..	177,983	155,205
Total value of chemicals	..	..	497,239	490,991

EXPORTS OF MISCELLANEOUS ARTICLES FOR MONTH  
ENDING 31ST MAY.

Articles.	Quantities.		Values.	
	1893.	1894.	1893.	1894.
Gunpowder..... Lb.	727,800	721,100	£ 18,066	£ 18,864

## Monthly Patent List.

\*The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

9815. P. M. F. Laurent. Improved apparatus for sterilizing liquids, applicable also for heating, cooling, condensing, distilling, and other similar purposes. Filed May 19. Date applied for November 20, 1893, being date of application in France.

9958. T. Craney. Improvements in evaporating apparatus. May 22.

9959. T. Craney. Improvements in evaporating apparatus. May 22.

10,523. J. F. Beins. An improved method of and apparatus for saturating liquids with gases. May 30.

10,906. A. Chapman. Improvements in apparatus for evaporating brine or other liquors or solutions, and extracting the salts or other solid matters therefrom. June 5.

11,226. D. B. Morison. Improvements in apparatus for heating, evaporating, or condensing. June 9.

11,354. J. Wilkinson. Improvements in furnaces applicable to metallurgical, chemical, and other purposes. June 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1893.

1017. G. Pettigrew. Improved still and apparatus for the distillation of ammoniacal liquor and other fluids, and the manufacture of sulphate of ammonia. May 30.

10,427. T. E. Mitton. An improvement in pressure-gauges and vacuum-gauges. May 30.

12,528. A. Lavy. An improved distilling apparatus. May 23.

13,567. V. Edwards. Copper distillation flask. May 30.

13,784. J. Horne. Improvements in means for mixing or blending liquids. May 23.

15,622. A. E. H. Field. An improvement in compound asbestos and other fibrous packings. June 20.

16,198. W. C. Currie and W. E. Rowlands. An improvement in apparatus for drying animal and other matters. June 6.

1894.

7027. L. Wagner and J. Marr. New or improved process and apparatus for purifying liquids. May 30.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

9709. E. Mason. Fuel economiser. May 18.

9913. W. P. Thompson. Improvements in separating gases and in apparatus therefor. May 22.

10,029. R. Fegan. Improvements in compressed fuel. May 23.

10,438. G. S. Cory and C. Cory. Improvements in the manufacture of artificial fuel. May 29.

10,184. T. A. Garnett, G. Forster, D. Lister, H. Taylor, and F. Birchall. Improvements in carbonising coal or other gas. May 30.

10,772. A. J. Tempire. Process of deodorizing petroleum and other hydrocarbons. Filed June 2. Date applied for December 4, 1893, being date of application in France.

11,256. J. Ormerod. Improvements in and connected with gas carbonising apparatus. June 11.

11,432. G. N. Stockman. Cylinder to increase the illuminating power of gas in lighting railway carriages. June 12.

11,522. N. K. H. Ekeland. Apparatus for the manufacture of coal powder of peat, saw-dust, and such like. Complete Specification. Filed June 13. Date applied for November 29, 1893, being date of application in Sweden.

11,536. J. T. Kay, J. W. C. Holmes, and P. F. Holmes. Double or single incline retort for the destructive distillation of coal or other material, for the production of gas for illumination and other purposes. June 14.

11,645. A. Mortimer. An improved fire-lighter. Complete Specification filed June 15. Post-dated April 20, 1894, and re-numbered 11,645.

11,657. J. T. Westcott. Improvements in apparatus for the manufacture of water-gas. June 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

5647. J. H. R. Dinmore. Improvements in or connected with the manufacture of gas. June 20.

12,440. L. Mond. Improvements in obtaining combustible gases, ammonia, and tar from fuel, and in apparatus therefor. June 13.

12,903. J. Bowing. See Class III.

14,918. Brin's Oxygen Co. Lim., and K. S. Murray. Improvements in or connected with the production of oxygen from atmospheric air, and apparatus to be employed therein. June 13.

21,089. C. D. Abel. — From the Gas Motoren Fabrik Deutz. Improvements in gas producers. June 13.

1894.

7372. M. Bernstein and A. Silbermann. Improvements in and relating to incandescent gas lighting. June 13.

7527. C. Barker. An improved fire-lighter for lighting coal or coke fires. June 6.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

4097. J. A. Wanklyn and W. J. Cooper. Improvements in the distillation of petroleum. May 30.

12,440. L. Mond. See Class II.

12,903. J. Bowing. Improvements in coking processes and apparatus, and in the recovery of the products of distillation. June 13.

## IV.—COLOURING MATTERS AND DYES.

## APPLICATIONS

9529. S. Pitt.—From L. Cassella and Co., Germany. The production of polyazo-dye-stuffs from gamma-amidonaphtholsulpho acid. May 15.

9610. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of colouring matters and materials therefor. May 16.

9611. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of colouring-matters. May 16.

9681. H. E. Newton. From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of chemical compounds derived from amidoazobenzene or analogues thereof and suitable for use in dyeing and printing. May 17.

9806. J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran. Manufacture of new violet, blue, grey, and black substantive colouring-matters for dyeing cotton. Complete Specification. May 19.

9856. C. D. Abel.—From The actien Gesellschaft für Anilin Fabrikation, Germany. Improvements in the manufacture of colouring-matters dyeing blue with mordants. May 21.

10,194. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of new dyes of the rhodamine series. May 25.

10,218. A. Zimmermann.—From The Chemische Fabrik auf Actien vormals E. Schering, Germany. The treatment of phenols and phenol derivatives and the production therefrom of hydroquinone, hydroxylated phenol derivatives and allied bodies. May 28.

10,333. J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran. Manufacture of new colouring matters varying from blue-violet to blue-green. Filed May 28. Date applied for, October 31, 1893, being date of application in France.

10,854. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture of colouring-matters related to the indulines and eurhodines June 4.

11,157. S. Pitt.—From L. Cassella and Co., Germany. The production of phenyl-amido-oxynaphthaline sulpho acid, and of colouring-matters deriving therefrom. June 8.

11,216. A. Wohl. Manufacture of hydroxylamine, hydrazine, and derivatives thereof. June 9.

11,569. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of red dye from paranitro-aniline. June 11.

11,641. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Process for production of black azo dyes on the fibre. June 15.

11,708. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improved manufacture of paramethoxy and para-ethoxyphenyl-urea. June 16.

11,717. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of colouring matters. June 16.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

12,323. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co. Improvements in the manufacture of colouring matters. May 30.

13,833. C. D. Abel.—From The Actien Gessellschaft für Anilin Fabrikation. Manufacture of mordant-dyeing colouring matters. May 23.

14,014. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The manufacture and production of new basic colouring matters. May 23.

14,345. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Improvements in the manufacture or production of colouring matters derived from anthraquinone. May 30.

14,671. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Improvements in the production of green and bluish-green colouring matters. June 13.

14,678. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The manufacture and production of new amido-sulpho acid, and of new azo dyes therefrom. May 23.

14,895. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Improvements in the manufacture of colouring matters. June 6.

15,045. H. E. Newton. From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of dye-stuffs. June 13.

15,080. H. H. Lake.—From Messrs. Wirth and Co., agents for A. Leonhardt and Co. Improvements in the manufacture of colouring matters. June 6.

15,223. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Improvements in the manufacture or production of naphthylamine sulpho acids. June 13.

15,327. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Production of para-ethoxy and of para-methoxy-phenyl-succinimides. June 20.

15,328. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Improvements in the production of iodo-derivatives of the succinimide and of substituted succinimides. June 20.

15,444. S. Pitt.—From L. Cassella and Co. The production of new acetonaphthylenediamine sulpho acids and of colouring matters derived therefrom. June 20.

15,509. R. G. Williams. Improvements in colouring matters. May 30.

16,370. R. Willcox.—From The Badische Anilin und Soda Fabrik. The manufacture and production of new acid colouring matters. June 6.

23,578. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. Manufacture of colouring matters applicable to unmordanted fibres or fabrics. June 6.

1894.

8536. F. Petersen-Møller. Manufacture of colouring matters, dyeing unmordanted cotton, and their salts and sulpho-derivatives. June 6.

## V.—TEXTILES, COTTON, WOOL, SILK, Etc.

## APPLICATIONS.

10,337. H. Cohrs and J. Oesterreich. Process and composition for waterproofing textile materials or fabrics and finished garments. May 28.

10,450. H. F. Moreau and L. Canivet. The manufacture and production of a new kind of lace. May 29.

10,542. J. Campbell. Improvements in the method or process of washing "waste" silk. May 31.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

11,110. T. Birnbaum. Improvements in the manufacture of coloured waterproof fabrics. May 23.

13,921. F. Walton. Improvements in apparatus for the manufacture of mosaic floorcloth. May 23.

14,551. G. MacFaur. Improvements in the manufacture of flax or vegetable fibre roofing. May 30.

15,357. J. F. Coates. Improvements connected with the printing of fabrics such as oil cloths, linoleum, and other like flexible substances. June 20.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

### APPLICATIONS.

9524. L. Schaefer. Improved method of and apparatus for marking patterns on fabrics. May 15.

10,391. F. A. Blair. Improvements in apparatus for dyeing or otherwise treating with liquids textile materials in a more or less manufactured condition. May 29.

10,392. J. Pritchard. Improvements in apparatus for dyeing yarns and slubbings or rovings or otherwise treating the same with liquids. May 29.

10,466. E. B. Manby. An improved medium or vehicle for thickening and fixing calico printer's pigments, colours, and mordants, and for use as an improved albumen substitute in calico printing and dyeing. May 30.

10,564. J. Tait. Improvements in bleaching jute. May 31.

11,077. E. Hoffmann. Improvements relating to dyeing wool with chromium lakes. Complete Specification. June 7.

11,641. O. Imray.—From The Farbwerke vormals, Meister, Lucius, and Brüning, Germany. See Class IV.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

14,154. J. O. Obermaier. Improvements in or relating to dyeing apparatus. May 23.

14,656. W. Hadfield, J. J. Sumner, and H. Hadfield. Improvements in and apparatus for printing fabrics. June 6.

15,028. J. Clapham, J. Picard, C. Villedieu, and W. W. L. Lishman. Improvements in the means and method of preparing vegetable and animal fibres, fabrics, or piece goods for the reception of aniline black. June 6.

15,326. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Improvements in the process for producing fast colours from direct dyes on cotton. June 20.

## VII.—ACIDS, ALKALIS, AND SALTS.

### APPLICATIONS.

9782. A. Campbell and A. Walker. Improvements in utilising acid sulphates and acids, and in obtaining nitric acid and hydrochloric acid. May 19.

9979. T. Craney. Improvements relating to the manufacture of sodium bicarbonate and to apparatus therefor. May 22.

10,127. T. Hawkins, S. H. Hawkins, and G. Newnham. A dichromate oxyhydrogen compound. May 25.

10,555. A. McDougall. Improvements in the manufacture of salts of ammonia. May 31.

10,589. O. Imray.—From P. Gredt, Belgium. Process for treating blast-furnace gases for the extraction of alkaline and ammonium compounds, such as iodides and iodine, therefrom. Complete Specification. May 31.

10,604. J. Y. Johnson.—From The Verein Chemischer Fabriken, Germany. A process of manufacture of chlorine from hydrochloric acid gas and nitric acid by the employment of sulphuric acid. May 31.

10,781. A. R. Davis. Improved apparatus for the manufacture of compounds of ammonia and carbonic acid. June 2.

10,782. A. R. Davis. Improvements in the manufacture of compounds of ammonia and carbonic acid. June 2.

10,983. E. Pew and W. Blenheim. The production of vinegar or acetic acid by means of ozone. June 6.

11,233. A. Crossley. An improved process and apparatus for the manufacture of zinc oxides, sulphates and sulphides, from zinc ashes, zinc blende, carbonate of zinc, and other ores of a complex nature, such as ores containing lead, zinc, silver, copper, manganese, iron, or other metals in combination. June 9.

11,655. J. Greenwood. Improvements in and connected with the manufacture or production of ammoniacal. June 15.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

10,171. G. Pettigrew. See Class I.

12,995. H. Lane and J. Pullman. An improved method of and apparatus for producing carbonic acid gas. June 13.

13,654. G. Lunge and F. Maxwell Lyte. Improvements in the production of nitric acid, caustic alkali, and ferric oxide. June 6.

13,708. Sir Lowthian Bell, Bart. Improvements in the treatment of bicarbonate of soda. May 23.

13,709. Sir Lowthian Bell, Bart. Improvements in evaporating saline solutions. May 23.

14,407. A. K. Huntington. An improved manufacture of compounds of iron with fatty acids. May 30.

19,539. R. E. Chatfield. A process for utilising acid sulphates of soda. May 23.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

### APPLICATIONS.

9546. H. J. Hadden.—From the Columbian Pottery and Brick Kiln Co., United States. Improvements in kilns. Complete Specification. May 15.

9554. W. W. Pilkington. Improvements in apparatus for the manufacture of sheet and plate glass with embedded metallic wire. May 16.

9860. F. W. Golby.—From M. Hoffmann, Germany. A process for producing pressed glass plates for lining walls, ceilings, and for similar purposes. May 21.

10,085. A. Cay. A new or improved manufacture of ornamental sheet glass. May 24.

10,117. E. M. C. Gondouin. Improvements in ovens or kilns for use in burning or baking articles of porcelain, earthenware, and the like, and in apparatus for use in connection therewith. May 24.

10,734. C. J. Hall. Improvements in and in the application of a certain composition or material specially suited for use in the plastic arts, such as the production of artistic objects in bas-relief, relief, or in the round. June 2.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

10,503. A. G. Brookes. From A. Kattenloft. Improvements in the manufacture of lamp glasses for safety-lamps and such like glasses for similar uses. May 30.

1894.

7412. W. Garraway. Improvements in the manufacture of caustic soda and potash, and of nitric and sulphuric acids. May 23.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

9511. H. C. Stephens. A process and apparatus for treating timber so as to modify its condition and preserve it from decay. May 15.

9545. A. Baubère. Improvements in continuous or running kilns for burning lime, cement, and other similar materials. May 15.

9559. F. W. Golby.—From C. Bayer, Austria. Improvements relating to the manufacture of inscriptions from or in artificial stones. May 21.

9948. H. Maurer. An improved process of manufacturing porous bricks. Complete Specification. May 22.

10,243. R. D. Bailey. Improvements in and appertaining to street pavements and house flooring. May 28.

10,416. J. Briggs. Improvements in kilns for burning limestone, cement, and other similar materials. May 29.

10,585. C. Geige. A new or improved method or process for the manufacture of artificial wood. May 31.

10,607. J. P. Brasseur and N. Lambert. A process for the production of cement from furnace slag. May 31.

11,704. L. Jones. Improvements in the manufacture of fireclay. June 16.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

13,386. H. Salmon and J. E. Whiting. New or improved substitute for pumice stone, and process of manufacturing the same. June 2.

15,496. The Alamant Company, Limited, and J. Wilkinson. A new or improved fire-proof flooring. June 6.

22,978. T. Potter. Improvements in the construction of fire-resisting floors. June 20.

1894.

8540. R. Stone. Improvements in the manufacture and treatment of fire-proof plastic material for cement. June 20.

## X.—METALLURGY, MINING, ETC.

### APPLICATIONS.

9536. A. G. Fell. Improvements in methods of treating lead ores. Complete Specification. May 15.

9578. C. T. J. Vautin. An improved process and means used therein for the production of an alloy of tin with the alkaline metals or metals of the alkaline earths. May 21.

10,197. C. T. J. Vautin. An improved process and means used therein for the production of metallic sodium and potassium from salts of the same. May 25.

10,249. G. Thomson. Improvements in obtaining gold and silver from ores, mattes, or other compounds. May 28.

10,322. J. P. van der Ploeg. Improvements in or relating to the extraction of gold and other precious metals from their ores, or other compounds, and the recovery of the solvents used in the process. May 28.

10,344. C. M. Pielsticker. Improvements in the extraction of gold and silver from ores. May 28.

10,439. A. H. Moore and G. Whitlock. Improvements in and relating to the manufacture of combined iron and steel ingots. Complete Specification. May 29.

10,478. T. W. Walker. An improved method of preparing iron or steel blooms, or billets to be used in guide and other small mills. May 30.

10,820. E. Böcking. An improved method or process of preparing moist purple ore (fine iron ore) for smelting. June 4.

10,827. M. Boly. An improved process for the chemical disaggregation of pyrites of complex composition with a view to rapid extraction of the metals contained therein, such as gold, silver, arsenic, antimony, and tellurium. June 4.

10,923. W. P. Thompson.—From E. Bertrand and O. Thiel, Austria. Improvements in the manufacture of steel. Complete Specification. June 5.

11,138. F. Siemens. A method of protecting iron, steel, or other metal from oxidation during heating. June 8.

11,148. W. P. Thompson.—From O. Nicolai, Germany. An improved flux for use in soldering aluminium and other metals. Complete Specification. June 8.

11,168. H. H. Lake.—From The Metallgesellschaft, Germany. Improvements in and relating to apparatus for use in the manufacture of sodium. June 8.

11,274. J. D. Wilson. Improvements in tuyères for blast furnaces and cupolas. June 11.

11,307. C. Hoepfner. An improved method or process for the treatment of the ores of nickel and cobalt. June 11.

11,447. J. J. W. Carr. Improvements in furnaces for melting, heating, or annealing metals, metallic alloys, and the like. June 13.

11,570. S. Hufty and J. K. Caldwell. Improvements in methods of partially decarbonising and converting iron and increasing carbon in wrought iron and steel. June 14.

11,574. H. R. Müller and F. O. Müller. A means or apparatus for producing pure castings. Complete Specification. June 14.

11,724. C. Hoepfner. Improvements in the treatment of calamine and similar minerals for the extraction of zinc. June 16.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

8964. J. A. Mays. Separating and purifying metals. June 13.

12,647. W. Mills. Improvements in metallurgy. May 13.

12,979. J. W. Hall. An improved process for treating complex and refractory ores and materials, and obtaining the metals and pigments therefrom. June 6.

13,817. R. A. Hadfield. Improvements in the manufacture of what is known as manganese steel. May 30.

15,117. R. Howarth. Improvements in the manufacture of metallic alloys or compounds. June 20.

15,949. O. Imray.—From B. T. Laey and J. Storer. Improvements in dissolving, leaching, and filtering ores or minerals, and apparatus for that purpose. May 30.

1894.

8085. P. C. Choate. Improvements in the art of producing metallic zinc. June 6.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

9761. T. Craney. Improvements in electrolytic apparatus. Complete Specification. May 18.

9862. W. Morison. Improvements in batteries. Complete Specification. May 21.

9949. T. Craney. Improvements in electrolytic apparatus. Complete Specification. May 22.

9975. W. P. Thompson.—From C. L. Collin, United States. Improvements in the method of, and apparatus for heating, welding, or working metals by electricity. Complete Specification. May 22.

10,032. E. Gautier. Improvements in, and connected with electrolysis, and in apparatus connected thereto. May 23.

10,169. G. R. Blot. Improvements in plates for secondary voltaic batteries. Complete Specification. May 25.

10,463. J. M. Moffat. Improvements in cells or boxes of electric batteries. May 30.

10,823. A. F. B. Gomes. A new or improved process for the extraction of aluminium from certain clays by electrolysis. June 4.

10,853. J. Y. Johnson. From La Société L'Accumulateur Fulmen, France. Improvements in electrical accumulators or storage batteries. Complete Specification. June 1.

10,952. C. Hoepfner. Improvements in electrodes. June 5.

11,312. H. H. Lake. From La Société Electrogenique, France. Improvements in electric accumulators or secondary batteries. June 11.

11,587. L. P. Hulin. Improvements in the process of and apparatus for the electrolytic decomposition of solutions and for the immediate separation therefrom of the liquid or dissolved electrolytic products. Filed June 14. Date applied for, November 25, 1893, being date of application in France.

11,606. F. R. Davenport. Improvements in separators for electric storage cells. June 15.

11,664. T. Drake. An improved method, means, or process of producing caustic soda and chlorine gas, or caustic potash and chlorine gas, by the electrolysis of common salt in solution, or chloride of potassium in solution. Complete Specification. June 16.

### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

4106. L. Epstein. A process for maintaining positive plates of secondary voltaic batteries in good operative condition. May 30.

13,317. The Lithanode and General Electric Co., Limited, and J. T. Niblett. Improvements in secondary electric batteries. June 13.

13,336. C. Hoepfner. Improvements in the electrolytical production of nickel and other metals. May 30.

15,396. F. Hurter. Improvements in and connected with apparatus for the manufacture of chlorate of potash by electrolysis. June 20.

1894.

6046. L. A. P. Lienard and H. E. A. Lienard. Improvements in the methods of effecting the electrolysis of saline solutions. June 20.

7985. T. Drake. An improved method, means, or process of producing caustic soda and chlorine gas by the electrolysis of common salt in solution. May 30.

8917. H. Alexander. Improvements in or in connection with apparatus for the electro-deposition of metals. June 13.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

9526. A. W. Winter. See Class XVIII.—A.

9888. N. Womersley and H. Mutell. Supo Gallienne. May 22.

10,222. H. J. Phillips. An instrument for ascertaining the degree of fluidity of several oils at various temperatures in one operation. May 28.

11,324. F. B. Aspinall. Improvements in the treatment of cotton seed oil. June 11.

### COMPLETE SPECIFICATION ACCEPTED.

1894.

8676. W. H. Horton. An improvement in what is commonly called dry soap or soap powder. June 6.

## XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

### APPLICATIONS.

9655. J. S. MacArthur. Improvements in making white lead. May 17.

9823. D. Coventry. Whitish, being an improved flat size-colour for painting and shading purposes. Complete Specification. May 21.

9,883. L. L. B. Meyer. New or improved manufacture of varnish or of a substance for use in making varnish. May 21.

10,230. E. J. T. Digby. A new or improved manufacture or material for "colouring," polishing, or burnishing. May 28.

10,424. P. F. Johnson. Improvements in the manufacture of plumbago or graphite, commonly called black lead. Complete Specification. May 29.

10,531. C. P. Shrewsbury and H. R. Gregory. Improvements in the manufacture of lead pigments. May 31.

10,676. E. F. Wailes. Non-conducting bituminous composition for protecting the surfaces of structures from waste or decay. June 1.

11,398. W. G. Murray. A new and improved varnish for violins and other articles. June 12.

11,454. J. Hargreaves and T. R. Hewlett. Improvements in the manufacture of pigments. June 13.

### COMPLETE SPECIFICATION ACCEPTED.

1893.

12,979. J. W. Hall. See Class X.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

### APPLICATIONS.

10,151. E. T. Day and T. W. Matthews. Improvements in the treatment of raw hide, and the subsequent use and application of the same. May 25.

10,154. W. A. Lamplugh. A new or improved composition for cleaning, softening, and waterproofing leather, and for other purposes. May 25.

10,361. F. Searis-brick. Improvements in apparatus for boiling size. May 28.

11,381. W. H. E. Boulton. Improvements in or relating to the manufacture of cement, applicable for leather belting and other purposes. June 12.

11,426. P. C. Hewitt. Improvements in processes and apparatus for cooling glue and forming it into sheets. June 12.

11,678. W. J. P. Peacock. An improved method of drying albumen of eggs. June 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

19,481. N. Kumagaya. A new or improved material capable of being used in substitution for leather and for ordinary paper. June 6.

24,463. W. Zahn. Improvements in the art or process of tanning hides or skins. June 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

11,153. W. P. Thompson. — From 'The Actien Maschinenbau Anstalt vormals Vennet and Ellenberger, Germany. Improvements in the process of and apparatus for drying distillers' washes and the like, and for removing the acids therefrom. June 13.

12,609. P. W. May and B. E. R. Newlands. Improvements in and apparatus for sterilising or preventing fermentation or acetification of beers, beverages, or the like. May 30.

12,837. L. Lederer. Improvements in the manufacture of yeast and the distillation of spirits. June 13.

14,280. W. Watson. Improvements in and relating to the treatment of hops. June 6.

1894.

1717. R. R. P. Schmiedeecke and E. O. Gade. Improvements in apparatus for the preparation of malt. June 20.

### XV.—AGRICULTURE AND MANURES.

#### APPLICATIONS.

11,295. G. H. Richards. A new or improved composition or compound. June 11.

11,296. G. H. Richards. A new or improved composition or compound. June 11.

11,297. G. H. Richards. A new or improved apparatus for vaporising compounds or compositions for use in horticulture. Complete specifications. June 11.

### XVI.—SUGARS, STARCHES, GUMS, Etc.

#### APPLICATIONS.

9674. C. D. Abel. — From L. König, Germany. A process for deodorising and bleaching dissolved or fused amylaceous materials. Complete Specification. May 17.

9880. F. E. V. Baines. Improvements in the treatment of rice or other raw grain or other starchy substances for the production therefrom of a material suitable for use in brewing or for other purposes. May 21.

10,956. R. Wilson. Improvements in the manufacture of starch. June 6.

### XVII.—BREWING, WINES, SPIRITS, Etc.

#### APPLICATIONS.

9880. F. E. V. Baines. See Class XVI.

10,375. E. Manbré, J. L. Barrett, and C. N. Poehin. Improvements in the manufacture of malt and maltose extracts. May 29.

10,664. J. H. West. Improved means for cooling worts. June 1.

10,667. R. W. Preston and J. M. Hogarth. Improvements in or relating to the treatment of brewers' and distillers' mash, and the saccharine liquid or wort obtained therefrom. June 1.

11,019. A. Egestorff. Improvements in utilising spent hops. June 6.

11,310. H. H. Lake. — From P. W. Sothmann, Germany. Improvements relating to the ageing or maturing of wine, cognac, and other alcoholic beverages, and to apparatus therefor. June 11.

### XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

#### APPLICATIONS.

#### A.—Chemistry of Foods.

9526. A. W. Winter. Improvements in compound edible fats. Complete Specification. May 15.

9626. H. E. Hansen. Method of producing condensed milk. Complete Specification. Filed May 16. Date applied for October 27, 1893, being date of application in Sweden.

9765. T. P. Hawksley. A simple and effectual apparatus whereby milk may be sterilised or rendered absolutely free from disease germs and adapted for family use. May 19.

10,105. A. Bernstein. Improvements in the production of a peptonised alcoholic beverage from milk. May 24.

10,106. A. Bernstein. Improvements in the production of a peptonised beverage from milk. May 24.

11,393. W. F. E. Casse. Process and container for preserving milk, cream, and other liquids. June 12.

#### B.—Sanitary Chemistry.

9787. G. H. Wolstencroft. Improved means for precipitating the impurities in the waste or effluent water from bleach-works, dyeworks, and other places. May 19.

10,616. W. D. Scott-Moncrieff. Improvements in and apparatus for the treatment of sewage or other organically contaminated liquids. May 23.

10,228. W. H. Hill-Hartland. Improvements in deodorising and purifying sewage or other waste liquors containing organic matters, in combination with generating and storing electricity, and in means or apparatus therefor. May 28.

11,188. J. E. Keirby. Improvements in apparatus for supplying, precipitating, and purifying materials employed in the treatment of sewage and other analogous purposes. June 9.

#### C.—Disinfectants.

10,188. A. J. Boulton. — From F. Haase, Germany. Improvements in insecticides. Complete Specification. May 25.

10,445. C. T. Kingzett. Improvements in sulphur candles or fumigators. May 29.

10,816. S. A. Vasey and C. F. Townsend. Improved compound forming a disinfectant, deodorant, and antiseptic. June 4.

11,129. E. Clement. An improved wash or preparation to be applied to hop-vines and plants generally. June 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

##### A.—Chemistry of Foods.

1893.

13,600. L. C. Tipper. Improvements in the preparation and treatment of animal and vegetable substances and fruit, and compounding the same with other ingredients for use as human food. May 23.

13,704. H. H. Lake.—From Baron Helfried Kaiserstein. Improvements in and relating to the manufacture of food for horses. May 23.

14,894. C. Ekin and W. H. Thew. Improvements in or relating to the manufacture or preservation of condensed milk. June 13.

15,595. W. Kuebel and F. E. Sahlfeld. A fish extract or essence, and in utilising the residual or waste products resulting from the production of the same. June 20.

15,757. J. Effront. Improved method and means for preserving food and other substances. June 15.

16,458. W. Brothers. Improved baking powder. May 30.

1894.

7543. E. O. Tatlin. An improved composition for use as food, and method of preparing the same. May 30.

##### B.—Sanitary Chemistry.

1893.

13,154. W. E. Adeney and W. K. Parry. Improvements in the purification of sewage and other like waste liquids, and in apparatus employed therein. May 30.

14,642. R. C. Tanner. Improvements in the treatment of sewage and other foul waters. June 13.

14,801. C. A. Burghardt. Improvements in and in the production of compositions adapted to be used in the treatment of sewage and other foul waters. June 6.

##### C.—Disinfectants.

1893.

14,411. I. S. McDougall and J. T. McDougall. Improvements in fumigants. May 30.

14,412. I. S. McDougall and J. T. McDougall. Improvements in the production of insecticides. May 30.

14,903. C. T. Kingzett. Improvements in sulphur candles or fumigators. June 6.

#### XIX.—PAPER, PASTEBOARD, Etc.

##### APPLICATION.

11,264. J. Hargreaves and T. R. Hewlett. Improvements in or applicable to paper making. June 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

12,420. W. Borland. Improvements in apparatus for mixing and regulating paper stuff. May 30.

19,481. N. Kumagaya. See Class XIV.

1894.

6221. G. Fehrenbach and L. Prud'hon. An improved process for producing artificial whalebone and method of forming same into strips. June 6.

#### XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

##### APPLICATIONS.

9675. C. D. Abel.—From C. Pieper, Germany. Improvements in the production of dextrins and leucocenes. Complete Specification. May 17.

9676. C. F. Cross and E. J. Bevan. Manufacture of cellulose acetate. May 17.

10,112. S. Pitt.—From The Chemische Fabrik auf Actien vormals E. Schering, Germany. The production of homologues of vanillin. May 21.

10,375. E. Manbré, J. L. Bairett, and C. N. Pochin. See Class XVII.

10,793. H. Baum. A process for obtaining the higher homologues of pyro-catechine. June 2.

11,128. E. H. Wild. Glucine. June 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

13,401. J. Bertram. Manufacture of geraniol,  $C_{15}H_{12}O$ , from citronella-oil. May 23.

13,478. A. W. Macellwaine and G. G. M. Hardingham. Improvements in or in connection with the extraction of oil by volatile solvents, and apparatus therefor. May 23.

21,417. A. R. Ling. A new improved process for the manufacture of anhydro-ortho-sulphaminobenzoic acid (orthobenzoic sulphinide) or of its salts, from commercial saccharin. June 20.

#### XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

##### APPLICATIONS.

9479. R. Berl. An improved method of tinting or colouring photographic prints. May 15.

10,202. G. T. Teasdale-Buckell. Improvements in the production, by the aid of photography, of pictures or representations in colours, and in means or apparatus employed therein. May 28.

10,766. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Germany. Production of coloured pictures by means of diazo compounds. June 2.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

14,024. F. C. D. Beacham. Improvements in or relating to colours for and colouring photographs and other articles. May 30.

21,487. A. Burchett. Improvements in photography. May 23.

1894.

6590. E. J. Tobin and F. G. Bement. Improved actinic prints and improved method of producing same. May 30.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATIONS.

- 11,508. J. Hauff. Employment of trinitroresorcin as a less driving powder. Complete Specification. May 19.
- 11,533. W. Schael and C. Schael. Improvements in matches. June 5.
- 11,553. R. E. Brown and C. O. Lundholm. Improvements in the manufacture of explosive compounds. June 13.
- 11,490. W. J. Mimpriss. Improvement in wooden matches. June 13.
- 11,582. A. V. Newton. — From A. Nobel, France. Improvements in the manufacture of explosive compounds. June 14.
- 11,644. A. V. Newton. — From A. Nobel, France. Improvements in explosive compounds. June 15.

## COMPLETE SPECIFICATION ACCEPTED.

1893.

- 11,645. A. V. Newton. — From A. Nobel. Improvements in explosive compounds. June 6.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPLICATION.

- 11,222. H. J. Phillips. See Class XII.

# THE JOURNAL

OF THE

# Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 7.—VOL. XIII.]

JULY 31, 1894.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2 6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S. ....	1881—1882.
Sir Frederick Abel, Bart., D.C.L., F.R.S. ....	1882—1883.
Walter Weldon, F.R.S. ....	1883—1884.
W. H. Perkin, Ph.D., F.R.S. ....	1884—1885.
E. K. Muspratt ....	1885—1886.
David Howard ....	1886—1887.
Prof. James Dewar, F.R.S. ....	1887—1888.
Ludwig Mond, F.R.S. ....	1888—1889.
Sir Lowthian Bell, Bart., F.R.S. ....	1889—1890.
E. Rider Cook ....	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S. ....	1891—1892.
Sir John Evans, K.C.B., F.R.S. ....	1892—1893.
E. C. C. Stanford ....	1893—1894.

## COUNCIL FOR YEAR ENDING JULY, 1894.

**President:** Prof. T. E. Thorpe, F.R.S.

### Vice-Presidents:

Sir F. A. Abel, Bart., F.R.S.	Sir John Evans, K.C.B., F.R.S.
Hornee T. Brown, F.R.S.	E. K. Muspratt.
H. Brunner.	Dr. W. H. Perkin, F.R.S.
John Calderwood.	John Spiller.
Chas. Dreyfus.	E. C. C. Stanford.
Dr. A. Dupre, F.R.S.	Prof. W. A. Tilden, F.R.S.

### Ordinary Members of Council:

R. Forbes Carpenter.	Prof. A. K. Huntington.
Frank Clowes, D.Sc.	Manning Prentice.
Thos. Fairley.	G. N. Stoker.
C. A. Fawcitt.	Wm. Thorp, B.Sc.
Prof. G. G. Henderson, D.Sc.	T. Tyrer.
David Howard.	Frank Wilson.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

**General Secretary:** Charles G. Cresswell.

**Offices:** Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

The President.

A. H. Allen.	Prof. A. K. Huntington.
L. Archbutt.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	C. Clarke Hutchinson.
Joseph Bernays, M.I.C.B.	Wm. Kellner, Ph.D.
H. Brunner.	Ludwig Mond, F.R.S.
E. Rider Cook.	B. E. R. Newlands.
W. Y. Dent.	John Pattinson.
Chas. Dreyfus, Ph.D.	W. H. Perkin, Ph.D., F.R.S.
Sir John Evans, K.C.B., F.R.S.	H. R. Procter.
Percy Gilchrist, F.R.S.	Roberton Redwood.
John Heron.	Joan Spiller.
D. B. Hewitt, M.D.	Wm. Thorp.
David Howard.	Thomas Tyrer.
Prof. J. J. Hummel.	

### Editor:

Watson Smith, 31, Upper Park Road, Haverstock Hill, N.W.

## NOTICES.

Notice is hereby given that, in accordance with the alterations in Rule 27 sanctioned at the Annual General Meeting in Edinburgh, all new members elected after January 1st next, and also those elected after the date of this notice who do not pay subscription for 1894, will be required to pay an entrance fee of one guinea. In accordance with the same rule the Life Composition Fee will be 20*l.*, instead of 15*l.* as heretofore, after the 1st January next.

## BANKERS' ORDERS.

For the convenience of Members, the Treasurer has arranged with the Bankers of the Society that they shall collect subscriptions from Bankers in town and country; and Members, who have not already done so, are invited to fill up and sign the Banker's Order enclosed with the December number of the Journal, which should then be sent to the Honorary Treasurer, Mr. E. Rider Cook, East London Soap Works, Bow, E.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

Notice is hereby given that the next List of Members will contain the professions or business occupations of the Members of the Society. Any Member who desires to confirm or alter his description as given before election should communicate with the General Secretary.

Attention is directed to a table showing the course of average prices of general commodities in England, compiled by Mr. A. Sauerbeck, F.S.S., which is contained in the Trade Report of this number of the Journal.

## LIST OF MEMBERS ELECTED 18th JULY 1894.

Bishop, Jos. T. F., 123, Cottenham Street, Chorlton-on-Medlock, Manchester, agent.

Breyer, Theodor, c/o The American Glucose Co., Peoria, Ill., U.S.A., chemist.

Charlton, H. C., The Dales, Whitefield, near Manchester, cloth finisher.

Charlton, Robt., The Dales, Whitefield, near Manchester, cloth finisher.

Douglas, London M., 112, Tooley Street, London, S.E., chemical manufacturer.

Ingalls, Walter R., No. 12, Old Slip, New York, U.S.A., metallurgist.

Jenkins, Jno. H. B., Laboratory, G.E.R. Works, Stratford, E., analytical chemist.

Lenders, A. W. H., Portsmouth, Bay Co., Mich., U.S.A., technical chemist.

Marshall, Jas., 7, Buchanan Terrace, Paisley, N.B., chemical student.

Miller, Dr. Jno. A., Niagara University, 203, Ellicott Street, Buffalo, N.Y., U.S.A., professor of chemistry.

Nesbit, Jas., 19, Wellington Street, Portobello, Edinburgh, chemical student.

Parkes, Harry, 25, Halkyn Avenue, Sefton Park, Liverpool, copper smelter.

Rowlands, W. Ellison, 34, Tynwald Hill, Stoneycroft, Liverpool, paint manufacturer.

Scott, J. Gillespie, Annislea, Northfield, Liberton, near Edinburgh, analytical chemist.

Tucker, Alex. E., 35, Paradise Street, Birmingham, metallurgical chemist.

White, J. Freebairn, c/o Cassel Gold Ext. Co. Lim., 13, West Scotland Street, Kinning Park, Glasgow, chemist.

Wright, Sidney B., Lincarfe, Albemarle Road, Beckenham, Kent, analytical chemist.

Yocum, Dr. John H., 78, Gold Street, New York, U.S.A., chemist.

## CHANGES OF ADDRESS.

Allen, R. L., 1/o Heaton Chapel; Brookfields, Middlewich, Cheshire.

Babington, P., 1/o Dudley Road; 19, Culverdon Park Road, Tambridge Wells.

Barratt, Alex., 1/o North Wales; c/o Barratt Bros., 5, 26th Street, Birmingham, Ala., U.S.A.

Biggs, B., 1/o 3; Vestry House, Laurence Pountney Hill, E.C.

Bird, H., 1/o Mutley; South Down House, Millbrook, Plymouth.

Bloxam, A. G.; Journals to 16, Bolingbroke Road, West Kensington, W.

Boake, E. J., 1/o Highgate; 11, Christchurch Road, Crouch End, N.

Bradburn, J. A., 1/o Solvay Process Co.; 1816, West Genesee Street, Syracuse, N.Y., U.S.A.

Cooper, H. P., 1/o Upper Holloway; 2, New North Road, Hoxton, E.

Cowburn, W. H., 1/o Cheetham Hill; Sutton House, Ashley Road, Bowdon, Cheshire.

Crawley, A. H., 1/o Leeds; 205, Westminster Road, Liverpool.

Donald, Wm., 1/o Eglinton Street; Salteoats, Ayrshire, N.B.

Dreaper, W. P., 1/o London; 15, Prince's Road, Great Yarmouth.

Duncan, Jas., 1/o Biarritz; c/o Mrs. Mowbray, Gartmore Villa, Rocheliff, Dalbeattie, N.B.

Fogg, Jas., 1/o Glasgow; 720n, Old Kent Road, London, S.E.

Frew, Dr. W., 1/o München; 2, King James' Place, Perth, N.B.

Fulton, Robt., jun.; Journals to Baldorran, Salteoats, N.B.

Gilchrist, P. C., 1/o Westminster; Frogual Bank, Finchley Road, N.W.

Greiff, R. W., 1/o Mincing Lane; 3, Eastecheap, E.C.

Heal, Carlton, 1/o Leeds; Hertford Lodge, Church End, Finchley, N.

Haywood, J. H., 1/o Holland Street; Sparth Cottage, Manchester Road, Rochdale.

Holloman, F. R., 1/o Custom House; 396, Barking Road, Plaistow, E.

Horie, G. H., 1/o Nobel's Villas; Glendye Cottage, Stevenston, Ayrshire.

Ingle, Dr. H., 1/o München; Poel, near Leeds.

Joseland, W. H., 1/o Chesterton; Taike, near Stoke-on-Trent.

Joynson, F., 1/o Barnsley; Killamars, near Rotherham.

Kay, Dr. P., 1/o Leiden; Lilymount, Heaton Road, Manningham, Bradford.

Lowson, J. G. F., 1/o Beltonford; Polton Paper Works, Midlothian, N.B.

Marshall, Wm., 1/o West Hill; 119, Drake Street, Rochdale.

Napier, Jno. W., 1/o Loanhead; Chemical Works, Addiewell, N.B.

Pitts, J. C., 1/o Sheffield; Rycroft Glen, Dore Station, near Sheffield.

Procter, H. R.; Journals to Thornleigh, Wheatley Road, Ilkley, Yorks.

Saltmarsh, J. G., 1/o Manchester; School Lane, Lostock Gralam, Northwich.

Smith, Watson, 1/o University College, London; 34, Upper Park Road, Haverstock Hill, London, N.W.

Spiller, J.; Journals to Cleveland Villa, Southwold, Suffolk.

Strangman, J. Pim; retain Journals until further notice.

Taylor, W. G. H., 1/o North Bow; 68, Woodlands Road, Ilford, Essex.

Turner, H. B. H., 1/o Cambridge; 4, Calverley Terrace, Tunbridge Wells.

Watson, C. E.; Journals c/o Peter Spence and Sons, Alum Works, Manchester.

Watson, D., 1/o Great Clowes Street; Willow Bank House, Kersal Vale, Manchester.

Welsh, Jas., 1/o Hayfield; Horrocks Lane Dyeworks, Red Bank, Manchester.

White, Henry, 1/o Carlisle; 8, Brown Street, Masboro', Rotherham.

Whitehead, W. T.; Journals to Magog, Province Quebec, Canada.

#### CHANGES OF ADDRESS REQUIRED.

Gibson, A. M., 1/o 11, Queen Victoria Street, E.C.

Harris, T., 1/o Union Acid Co., Runcorn.

Young, B., 1/o Home Lyn, Woodberry Down, N.

#### Deaths.

Clark, D. G., 44, St. John's Wood Park, N.W.

Wright, Dr. C. R. Alder, F.R.S., 3, Castellain Road, Maida Vale, W.

## PROCEEDINGS

OF THE

## THIRTEENTH ANNUAL MEETING.

THE Annual General Meeting of the Society in Edinburgh proved a successful gathering. The arrangements made by Professor W. Ivison Macadam, F.R.S.E., F.I.C., the honorary treasurer of the Scottish Section, and Mr. J. Stanley Muir, B.Sc., honorary secretary, though in some instances modified by the exigencies of the moment, showed extreme care and ability.

#### FIRST DAY.

THE Annual General Meeting was held on Wednesday, 18th July, in Queen Street Hall. The President took the chair at 10 o'clock.

#### WELCOME BY THE CITY OF EDINBURGH.

BALIE DUNLOP, on behalf of the Lord Provost, in welcoming the Society to Edinburgh, said he was not exactly sure if there was much in the city that called for their attention as experts. The city was, however, noted for the eminence and excellence of its educational institutions, and it occupied a prominent position in respect of the history of the country with which it was identified. The city itself was incomparable in regard to its beauty, and he hoped that the members of the Society would carry away with them pleasant and profitable recollections of all that might come under their observation. He further trusted that the arrangements which the Corporation had made for the comfort of the Society would meet with their approbation.

THE PRESIDENT thanked Balie Dunlop, in the name of the Society, for his very warm expression of kindness. He congratulated the city on the fact that the Lord Provost had gone that day to Windsor to receive from Her Majesty the very richly merited honour of knighthood. Those who had the pleasure of knowing him, knew that there never was an honour more richly and handsomely deserved. He hoped that when the Lord Provost came back from Windsor as Sir James Russell it would be to the still greater respect and esteem, if it were possible, of his fellow-citizens, who would honour, not the knight, but the man.

BALIE DUNLOP said he would have pleasure in conveying to the Lord Provost the handsome terms in which they had spoken of him.

THE Minutes of the Annual General Meeting in Liverpool having been read and confirmed, the Secretary read the

#### REPORT OF COUNCIL.

WE have the honour to report that the number of members on the register is 2,828, as compared with 2,784 at the last Annual Meeting. During the year, 244 new members have been elected and seven members have rescinded their resignations, making a total of 251 gains, as against 208 last year; while 207 have been removed by death, resignation, and other causes, as against 204 last year.

Among those who have died are Mr. Alexander Crum, of Thornliebank; Professor C. W. Heaton, of the Charing Cross Hospital; Dr. J. M. Milne, of the Glasgow Royal Infirmary Medical School; Sir Alex. Orr Ewing; Mr. John Head, long associated with the late Sir Wm. Siemens; Mr. John May, founder of the firm of May and Baker; Mr. R. H. Davies, of the Apothecaries' Hall, London; Dr. P. Norman Evans; and Mr. Alfred Solvay, of Brussels.

During the past session, 77 original papers have appeared in the Journal, as against 74 last year.

The excess of revenue over expenditure, as will be seen from the Treasurer's report already in your hands, amounted last year to 37*l.* 17*s.* 9*d.*, as against 59*l.* 12*s.* 4*d.* in 1892.

The Committee on Patent Law has held several meetings, and embodied certain suggestions in a circular which was issued to each member of the Society. Having discussed these suggestions, the various Sections were unanimously in favour of petitioning Parliament to grant a Royal Commission to consider the whole question. Since the Council received this expression of opinion, the course of public business has been such that it has been held inadvisable to approach Her Majesty's Government lest, by inopportune action, the object in view should be defeated.

Experience having shown that some modifications of the bye-laws are required, those which the Council, after careful consideration, has decided to propose, and which the members will be asked to accept at this meeting, were published in the April number of the Journal. If accepted, these modifications will raise the Life Composition Fee to 2*l.*, so as to bring it into a fairer ratio with the subscription; will require new members to pay an entrance fee of one guinea; will somewhat modify the method of retirement of members of Council; will regulate communications between the Sections and other public bodies; but will otherwise make changes only of wording and of arrangement.

It is with great pleasure that the Council announces that it has acceded to the request of some of our fellow-workers in the United States to form a Section in New York. This is the first time that such a request has been preferred from abroad, and marks a new stage in the history of the Society, the importance of which cannot be too highly estimated.

To all those who have contributed to the work of the Society, our hearty thanks are due.

Mr. A. E. FLETCHER, Her Majesty's Chief Inspector of Alkali Works, moved the adoption of the report.

Mr. R. PULLAR, Perth, seconded, and the motion was agreed to unanimously.

#### THE TREASURER'S REPORT.

The GENERAL SECRETARY submitted the report of the Hon. Treasurer, already published in the Journal (this Journal, June 1894, 574).

Mr. D. HOWARD said he had great pleasure in moving that the report of the Treasurer be received and adopted, and that a vote of thanks be accorded to him for his services. It was no light matter to undertake the treasurership of a great society like theirs, and it would be impossible to find a treasurer who took more thorough, business-like pains with it than theirs. Every detail, he knew, had his most careful consideration. The management of their funds was carried on at almost nominal expense, due to personal care and attention of their Treasurer. It was therefore in no formal manner that he put the motion.

Mr. J. M. GIBSON, Chester, said he had great pleasure in seconding the resolution proposed by Mr. Howard. The whole thing was exceedingly satisfactory, and as a non-official member he was exceedingly grateful.

The resolution was adopted.

#### ALTERATION OF BYE-LAWS.

Mr. T. TYRER, London, proposed the adoption of the alterations of the Bye-laws as recommended by the Council, and referred to in the report. The proposed alterations were as follows:—

1. That *Rule 7* be amended by the deletion of "and" in the first line thereof, and by the addition of the words "and 47" in the same line.

2. That *Rule 15* shall read as follows:—

"Four Ordinary Members of Council shall retire each year, and those who thus retire shall not be eligible for re-election to the Council, except under Bye-laws 14, 23,

and 24, until the Annual General Meeting next following that at which they retire. When an Ordinary Member of Council is nominated for election to the office of President, he shall not be counted among those who are to retire."

3. That the first sentence of *Rule 16* read as follows:—

"Except that any Ordinary Member of Council may be nominated for election to the office of President, and that such member, if any, shall not be included in the operation of the present Bye-law, the Ordinary Members of Council shall retire as far as may be possible in the order in which they were elected."

4. That *Rule 17* shall read as follows:—

"When an Ordinary Member of Council is nominated for election to the office of President, the Council shall nominate a Member for election as an Ordinary Member of Council in his place."

5. That under *Rule 18* the eighth line be amended to read as follows:—"and also the name of the person, if any, who has been nominated, &c., &c."; that the form of nomination of candidates for the Council be amended by transferring the candidate's declaration to the end thereof; and that the words "and by the nominee" be added in the third line after the above-mentioned form after the word "subscriptions."

6. That the proviso at the end of *Rule 22* be deleted.

7. That in *Rule 26* the Nomination Form for candidates for Membership be amended to read as follows:—

"We, the undersigned members of the Society of Chemical Industry, hereby propose  
(candidate's name in full) as a fit and proper person to become a member of the Society.

For names only of members }  
recommending the candidate. }

"And I, the said candidate for membership, hereby declare that if elected I will do my best to support the Society and will observe its Bye-Laws.

(Signature) \_\_\_\_\_ (Profession) \_\_\_\_\_  
(Address) \_\_\_\_\_ (Date) \_\_\_\_\_

Extract from Bye-Laws (Rules 27, 29, and 30).

8. That *Rule 27* should read as follows:—

"Each member shall pay an annual subscription of twenty-five shillings, due on the 1st January in each year; except that any member may pay a life composition fee of twenty pounds in lieu of an annual subscription. He shall also pay on receipt of notice of election an entrance fee of one guinea in addition to his first year's subscription; except that should a member who has paid an entrance fee resign and subsequently seek re-election the Council may dispense with a further entrance fee."

9. That in the second line of *Rule 28* the words after "and" read as follows:—"issued to the members once every year."

10. That *Rule 29* read as follows:—

"No person shall be entitled to the privileges of membership who has not paid his subscription for the current year. He shall not attend meetings nor vote, nor shall he receive gratuitously the publications of the Society. Should the subscription remain unpaid eight months after it is due, the Secretary shall give the member notice that unless payment be made within four months after the date of such notice, his name will be struck off the register. At the expiry of the said period, if the member should still remain in default, the Council may order his name to be removed from the register, whereupon he shall cease to have any right, privilege, or interest in the Society, and the Council may notify the same in the Journal, and recover the arrears of subscription at law."

11. That *Rule 30* read as follows:—

"Any member may withdraw from the Society at the end of any year by giving previous notice to the General Secretary of his intention to withdraw; always provided that such notice, to be valid, must be accompanied by the payment of all subscriptions, if any, which may be due from

him to the Society at the date of the notice. By such notice and payment he shall be released from all further liability as a member."

12. That the following rule be added after *Rule 53* of the present Rules

"All communications between Local Sections and Public Bodies or Societies shall be conducted through or be at the discretion of the Council; and no publication shall be issued by any Section to the general public without the previous consent of the Council."

13. That *Rules 54 and 55* be placed after *Rules 24 and 38* respectively, and that the succeeding Rules be renumbered accordingly.

Mr. CHAS. DREYFUS, Manchester, seconded.

Mr. J. M. GIBSON, Chester, said he did not rise for the purpose of pressing an amendment. Personally he was not interested, but a large number of young men whom they wanted to bring into the Society would possibly feel the entrance fee a hardship. It might not be so, but he had heard from some of them that it was so, and he had promised that he would mention the subject at that meeting. Looking at the state of the finances there seemed to be no necessity for it. They put more money on one side last year than they ever did before. Of course, if they were to go into a scheme for palatial buildings, the money might be required, but in the meantime they had sufficient funds, and this proposal might have the effect of shutting out some young men. He would respectfully suggest that a ballot should be taken of the Sections before these proposals were absolutely made into law.

Mr. TYLER explained that the Council considered that one way of preventing the constant leakage of membership which took place was to impose an entrance fee, because they thought that a man would consider before he lost an entrance fee of 21s. This would be lower than in other societies.

Mr. WM. THORP, B.Sc., London, called attention to the fact that both their subscription and the proposed entrance fee were extremely small, especially when they took into account the Journal they gave to their members. Some members seemed to want the Journal one year and not the next, which was very much to be regretted.

#### THE POWERS OF THE SECTIONS.

Mr. G. T. BEILBY, Edinburgh, called attention to the 12th clause of the alterations, relating to the powers of Sections. The subject, he thought, was of sufficient importance for the General Meeting to take some note of it.

Mr. HOWARD pointed out the importance of a Society like theirs being thoroughly unanimous, and the analogy there was in other similar bodies, such as Chambers of Commerce. In the majority of cases it was desirable that the whole weight of the Society should be thrown in any particular representation. It came very much stronger if, by waiting a very few weeks at the outside, the recommendation of a Section could go forward to any public body, or to the public, as the recommendation of the whole Society. This would be far better than that the Council should have to explain that the action of a Section was the action of a Section only, and not of the whole Society. There was just one other risk to be guarded against, and which every Section would desire to guard against for themselves, but in which they might possibly fail from not knowing what was going on in other Sections. They might find one Section opposing another. In such a case it was extremely desirable that the Council should know what was going on, and should have an opportunity of pointing out how a very different feeling might exist in another Section. The object of the rule was in every movement, if possible, to give the entire weight of the body, and to make it clear that it was not the opinion of a section only, but of the whole. They would thereby prevent chance and unintentional misunderstandings between Sections, a danger which

was not inconsiderable in public utterances. Their experience was that by extra care and extra consideration there was a gain and not a loss.

Mr. TYLER said that the object of the adoption of this rule would cause all influence to gravitate to the central institution was the furthest possible from the fact. There must be some centre, but still they should be a great federation, all bound together and no part separable from the other. Any man who looked at the foregoing could not fail to see that the same spirit animated them all. He had never seen the slightest indication whatever in the Council of a desire to criticise mildly, or to question motives, when any particular subject was brought forward from any particular Section. On the contrary, the wish of the Council was that if there were a strong movement on the part of any local Section in any matter, it should be confirmed in a broad spirit.

Replying to a question by a member, Mr. TYLER said he should say that the expression "local section," meant "local committee," because a local committee was assumed to represent a Section.

Dr. STEVENSON MACADAM, Edinburgh, was very glad that the subject had been brought forward. It appeared to him that there was no case whatever for interfering with the mode in which local Sections conducted their affairs. It appeared to him, besides, that they would be introducing a most dangerous element, because local men would be always thinking of what the Council in London might say about a matter. The Council in London might not have heard the evidence, nor seen the witnesses, and would, therefore, have to depend upon representations to be forwarded, which must be imperfect, and which might be partisan. At present if a Section forwarded a memorial to a public body, it was only a memorial from that particular Section, and did not bring the Society into any invidious position, even although the Section were going wrong. It was said that the Section would be strengthened if the Council in London supported them, but it would be the duty of the Council to support a Section if it approached a public body in a proper manner. Then and then only should come into force the element which had been referred to, viz., the Council giving the weight of their support to the Section. It appeared to him that the proposal would affect the freedom of action of the Sections. The wording was quite clear: the Sections were not to take action except after consulting the Council, and it appeared to him that there were questions affecting the industry which local Sections might have better knowledge, and better means of considering, than the Council.

Mr. A. ERNEST POWELL, Manchester, thought clause 12 was a most desirable one in the matter of advertising. It would prevent some who read papers from using them as a pure advertisement, which had been done. He thought it was most desirable that no Section should approach the public without the intervention of the Council.

Mr. DANIEL HARRIS, Edinburgh, did not quite follow a reference made to Chambers of Commerce, for this reason: that there were no National Chambers of Commerce, although there was an affiliation. They were really one Society; that he admitted at once; but it did seem as if the Council had gone too far in the direction they had gone. He admitted the argument of the Council, but thought their proposal would need to be modified. They in Scotland had a subject they were very much interested in, and they wished the Council to take it up, and he could not say that their action would be hindered thereby.

Mr. HOWARD explained that the London Chamber of Commerce had a great many different interests, and it was quite possible that, say, the West African Section might have very strong views upon a certain subject, which might be sent up to the Government of the day as the information of the Section, which the whole body would not be prepared to accept.

Mr. C. DREYFUS pointed out that they had already, by their third rule, resolved that the Council should have the management of the Society, and it was in order to emphasise this rule that clause 12 had been devised. Some

Sections had not at all conformed to Rule 3, but had acted independently without any reference to the Council. It was to stop such independent action, which sometimes operated very curiously on the Society, that the suggested rule was made. Local authorities did not know, sometimes, that the resolution of a local Section was not backed up by the whole Society, and clause 12 would prevent such a misunderstanding.

Mr. TYRER said they must bear in mind that the Sections were represented on the Council, and had the power to very largely influence the Council. The constitution of the Society was such that no Section could possibly complain that it had not opportunities of discussing any question before it.

Mr. REILLY said he had cast no reflection upon what the Society had done in the past. He wished to maintain the *status quo*; he thought it had worked very well in the past. He therefore proposed as an amendment that clause 12 be deleted.

Dr. STEVENSON MACADAM seconded.

Upon a show of hands the amendment was lost, and the original motion was then adopted by a large majority, and the proposed alterations were adopted *en bloc*.

#### ELECTION OF OFFICE BEARERS.

The GENERAL SECRETARY read the report of the scrutators, which stated that 46 ballot papers had been received, and that all the candidates proposed for election had been elected.

The composition of the new Council is as follows:—

##### President:

Prof. T. E. Thorpe, F.R.S.

##### Vice-Presidents:

Sir F. A. Abel, Bart., F.R.S.	Sir John Evans, K.C.B., F.R.S.
Hornee T. Brown, F.R.S.	E. K. Muspratt.
H. Brunner.	Dr. W. H. Perkin, F.R.S.
John Calderwood.	John Spiller.
Chas. Dreyfus.	E. C. C. Stanford.
Dr. A. Dupre, F.R.S.	Prof. W. A. Tilden, F.R.S.

##### Ordinary Members of Council:

R. Forbes Carpenter.	Prof. A. K. Huntington.
Frank Clowes, D.Sc.	Manning Prentice.
Thos. Fairley.	G. X. Stoker.
C. A. Fawcitt.	Wm. Thorp, B.Sc.
Prof. G. G. Henderson, D.Sc.	T. Tyrer.
David Howard.	Frank Wilson.

With the Chairmen and Secretaries of Sections.

##### Honorary Treasurer:

E. Rider Cook.

##### Hon. Foreign Secretary:

Ludwig Mond, F.R.S.

#### THE PRESIDENT'S ADDRESS.

When the Council of this great and influential Society invited me to become President, I fully realised for the first time the feelings of the old Highland retainer, when he was told to "come awa' and pe trooned the please the laird," seeing that whatever use my small efforts might be to the Society, I should certainly succeed in obliterating myself. But then it occurred to me that self-sacrifice is a Christian virtue, not too common, and that probably such an excellent opportunity of practising it might not again be presented to me; and after all it must be only a small sacrifice that I could offer on the altar of the Society we all revere so much and love so well.

With these feelings, therefore, of a stern sense of duty, I reluctantly accepted this honourable and difficult position, and assumed a chair which I have promised to occupy, but not to fill. Honourable, because any man may be proud of

having a band or even a finger in the building up of this Society, which is evidently destined to revolutionise the chemical industry of this country, by giving it that scientific character which must ever be the only sure foundation. Difficult, because it is no easy task to follow the eminent scientific men who have preceded me, and find something to say in the annual address which one or other has not already said infinitely better. We all abhor a vacuum, and perhaps there is nothing much nearer it than an empty address, and it is so easy to say something and so difficult to find something to say. Fortunately, however, our annual meeting offers many compensations for the penalty of listening to an indifferent address, and these will be amply secured in this beautiful city which the Society now visits for the first time. We have met once before in Scotland, in its great commercial centre, the city of Glasgow, celebrated, amongst other things, for the great extent and variety of its chemical manufactures. We shall not see the larger manufactures here; the tall chimney of the alkali works does not yet adorn the sky-line of this city, but there are many important specialities as well worth seeing; and we all owe her a deep debt of gratitude as the birthplace of chloroform. Modern Athens, with her lovely neighbourhood, combining mountain and flood, and full of historic traditions, is always attractive, and the hospitality of her citizens is proverbial.

We are also visiting our most northerly and one of our most active Sections, completing its decade this year, and hitherto the only one which represents a nation.

The progress of this Society is shown in the annual report presented at this meeting, and I have only to congratulate the members that it has so largely exceeded the most sanguine anticipations of the first promoters; that, although still in its teens, it presents all the characteristics of early and vigorous manhood. The Council, fortunately from the first, wisely recognised the paramount importance of a thoroughly progressive and educational journal; there was nothing of the kind then, and now nothing so good exists elsewhere. The Journal is so fully illustrated, and so cosmopolitan, and the field of view so comprehensive, that it appears to touch every trade and manufacture in the country, and that makes it deeply interesting to a very wide circle of readers. 3,200 copies are at present circulated all over the world, and we have reason to believe that it is as much studied and valued abroad as at home.

Whilst duly recognising the great value of the Journal, the members of this Society generally little know how deeply they are indebted to the watchful, unwearying labours of the Publication Committee, meeting monthly in London, where all communications are discussed and submitted to the most minute inspection. So long as they continue to devote so much time and attention to it, so long will it remain the first journal of applied chemistry in the world. Some of the best work of the world is done for nothing, but we ought all to be grateful to them for this devoted labour of love. So many valuable papers, and so much information, are contained in the twelve volumes already published, that I hope we may soon be able to afford a full and well-classified general index.

Is not our Journal now rather ahead of the national scientific and technical teaching? No doubt much has been lately done in this direction, but we are still far behind, especially in organic chemistry. According to Lunge, they have at the Polytechnic School at Zürich four full professors of pure and applied chemistry, with four assistant professors, and a fifth chair is just founded. Zürich has a population of 100,000; how many cities and towns of equal size have we with such advantages? Indeed, how many have we in this country, with 13 times the population of Switzerland and 25 times the revenue. Contrast this with the position of the Glasgow Technical College, founded as a people's university in 1796, in the second city of the kingdom, with nearly 3,000 students, doing a great educational work, but sorely hampered for want of funds. Or with our great metropolis, the largest and wealthiest city in the world, without an educational university. We ought for shame to hide our national head in our national pocket, which is quite big enough, if we will not put our hands there to supply such educational needs. Fortunately, we have at least one private citizen who has come from

Germany to reside amongst us, and who not only can point out our needs, but is ready to supply them. The munificent gift of Dr. Mond of the Davy-Faraday research laboratory to the Royal Institution is a noble contribution to our national scientific research. The modest and quiet way in which the large sum involved has been handed over astonishes all who do not personally know him. We who do know our former President, and our present perpetual honorary foreign secretary, as I hope he will allow me to call him, are not so much surprised at his great liberality; but we are proud indeed that he has enabled another former President, who presided when we last met in Scotland, and who occupies the chair of Faraday, to carry out what he proposed 50 years ago. I think not the least part of the value of this great gift will be the advantage of Dr. Mond's great experience in fitting up the research laboratory. We all wish the greatest success to this grand work, the national importance and results of which it would be impossible to over-estimate.

The main work of this Society is done in the various Sections, of which we have seven spread over the country, and all in such active work that the London Section has been obliged to call extra meetings to cope with the large number of important papers submitted to them. These sectional papers are remarkable for their great wealth of illustrations, and for the valuable discussions so carefully reported in the Journal, and thus appealing to a world-wide circle of chemists and others. We enter now upon a new phase: another national section has just been founded in New York. We have 310 members in the United States and Canada, and we heartily welcome our new Transatlantic Section, which, under the able chairmanship of Mr. A. H. Mason, is already sure of all the success we wish for it. We are pleased to add the stars and stripes to our highly respectable old colours, and to shake hands across the ocean with the great English-speaking race who "shall brothers be for a' that."

We have also 123 continental members, 103 in the colonies, and 21 in Japan; altogether we have 578 members residing abroad, or more than one-fifth of our whole number; but this is the first time any have been represented by a separate section, and I think the movement should be warmly encouraged and extended. Our Society furnishes an excellent combination of decentralisation with a central head directing. We have thorough local home-rule with imperial government; we have unity with strength, and peace with honour, and long may it continue so!

It has already done much to bring manufacturing chemists, who generally walked on opposite sides of the street, together for discussion of the many interests and difficulties they have in common.

We may look on the Journal and the Sections as now so well established that other fields may attract the attention of our future councils. This Society occupies a central and important position, which is quite unique, holding out the hand to assist science on the one side and commerce on the other.

It forms a connecting link between scientific societies and chambers of commerce, and will be essential and invaluable to both. You have only to look over the Journal to see that there is scarcely any science that is not introduced into its columns, or any trade which it does not affect.

We are the industrial and industrious descendants of the old alchemists, who spent fruitless days and weary nights in trying to discover the philosopher's stone, which was to turn everything to gold; we are still engaged in trying to extract the root of all evil from everything around us, and sometimes we also imitate our ancestors in putting more gold in than we take out.

The chemical manufacturer of to-day must practically know a little of everything. He must not only have a thorough knowledge of chemistry and physics, but he must be a good mechanical engineer and understand machine construction and mechanical drawing. Hence has arisen the important science of chemical engineering, the essential characteristic of which is that it deals with the devising of apparatus on the large scale with almost every known material. He has, moreover, to deal with all sorts of solids,

liquids, and gases, of all degrees of violence, of all kinds of gravities and pressures, in every variety of vessel, in shape, size, and material. The common laws affecting only water and air are not enough for him. He must also know electrical engineering, and may perhaps require to know this best. In fact, many of the greatest successes of the present day are due to increased knowledge of chemical engineering applied to old and well-known processes. The vacuum pan, the multiple evaporator, the filter press, the gas and petroleum engines, the mechanical and other refrigerators, the electric furnace, compressed gases, osmose apparatus, superheaters, and a host of other appliances have placed great powers in his hands, and he must know how to use them to the best purpose.

It was not always so. I have heard the question actually disputed as to whether it was at all necessary for a manufacturing chemist to know anything about chemistry, and have even known some who boasted that their success was due to their ignorance of the science. I remember, many years ago, a manufacturer showing me over his works, and, bestowing a hearty kick on a passing worker wheeling a barrow too slowly, remarked to me, "that's what I call chemistry," making me admit how little I knew about it, or about his rule-of-thumb or rule-of-toe method.

This was before the introduction of the Alkali Act, which has done much to improve our manufactures, and this year has placed 14 new groups of works under supervision, many of which required it badly. It is satisfactory to know from the Alkali Inspector's last report that the escapes of gases are now only about one-third of the permitted legal limit.

35,000 tons of sulphur are now produced annually from the obnoxious waste heaps, and this improvement may be traced back to the operations of this Act. But it is surprising to find that 15 per cent. of the sulphur passes through all the condensers. We did not expect that sulphuretted hydrogen and sulphurous acid would go off harmoniously together, but then neither could we anticipate that one work alone would have to deal with 5,000,000 cubic feet in 24 hours of a mixture of these gases and air.

No doubt perfect success requires a trinity of science, practice, and commerce; a perfect knowledge of pure chemistry, capacity for erecting plant and handling men, and commercial ability are qualities not often found under one hat; under three will do, if they work together. But there is still plenty of room for induction, observation, and experiment—at least our German rivals think so, for they go on different lines: they employ a large staff of really accomplished chemists, and keep many engaged on pure research. But then they believe in research and not in examinations; they keep their honours for originators. But we level down our future masters to a common pass examination, and the trade unions do the same for our men. Both repress excellence and exceptional ability—the very qualities which we ought to cultivate. And then what do we really mean by a works chemist? Is he not too often only a "tester"? And yet the manager in his too exclusive wisdom may be devoting his whole time to the saving of fuel and labour, little dreaming that some patient researcher in a far-off laboratory may be quietly undermining his whole work.

I think it could be easily proved that nothing ultimately pays better than original research, but it requires encouragement, for often the absolute necessity of living is against it, and a man may spend a lifetime on an important subject, doing great work, of which only those who survive him know the value. It is so true that "the human race is divided into two classes—those who go ahead and do something, and those who sit still and inquire why it wasn't done the other way."

The researcher will find that the latter class forms the bulk of his acquaintance. But is a man perfectly successful who fills his own pocket and adds nothing to the knowledge or welfare of the nation, and is he entirely unsuccessful who forgets his own pocket in his research after knowledge, but leaves the world better than he found it. I say no to both these propositions: I believe there is a higher life even in industrial chemistry.

Remember, for instance, our dear departed friend, Walter Wehler, whose name will never be forgotten by this Society,

which owes him so much: no one can say he made money on "his great work, but who does not revere the memory of the man who, as Dumas said, "cheapened every quire of paper and every yard of calico throughout the world." Or refer to another former President, W. H. Perkin, who still occupies a high position in organic research, and we hope he may long be spared to hew out new paths of inquiry: was he adequately remunerated for teaching the world how to make colours from a waste material, and for revolutionising the whole art of printing and dyeing?

The great success of these eminent chemists is not measured by their paltry money return, but by national results: they represent the higher life. This higher life can and ought to be promoted by this Society. Money is plentiful and should be profitably invested, but talent is scarce and ought to be encouraged. I think we might devote some of the former to bring out some of the latter: in other words, that prizes should be given to promote original research, as is done by some of the smaller societies abroad. The Industrial Society of Mulhouse, for instance, offers this year for various researches, 160 prizes in medals and sums ranging from 400 to 5,000 francs. Certain rules might be drawn up, and certain suggested lines of inquiry outlined and published in the Journal. Many manufacturers could suggest subjects worth working on, and some might be induced to assist in providing the money for the prizes under certain conditions.

I think also that our Society might be made more attractive to these flocks of young chemists who crowd all the gangways leading to the Chemical Society, under the impression that the title F.C.S. will give them a proper hall-mark qualification, which the President has assured us it does not. Now most of these young men will come into manufacturing laboratories.

May we not some day model our Society more on the lines of the Institute of Civil Engineers, which it resembles, and admit students, associates, and members, who must give evidence of careful training before election, and adopt for these the title of C.I. or industrial chemist, and make it a qualification worth having. These young men may pass the examinations of the Institute of Chemistry, they may join the Society of Analysts, they may swell the ranks of the Chemical Society, but they must join the Society of Chemical Industry: they may read the other journals, but they must read ours if they are to keep abreast of the progress of applied chemistry.

I am one of those who think that mechanical engineering can only be learnt in the machine shop, and that applied chemistry can only be learnt in the works. A young man going into it should begin by connection with this Society as a student; he should undergo a certain curriculum or pupillage with a member, as in the Engineers, who will testify, for instance, that he is well up in technical and proximate analysis, or that he has conducted a department in the works with ability, and that should be his hall-mark of qualification; that if he misbehaves—betraying laboratory or trade secrets, for example—he will lose it.

May we not hope in some such way to fix the foundations of this Society, so that it may ultimately rest on merit and merit alone.

A royal charter would be required, and a larger house and a better home in London would be useful to the Society in many ways.

Of course it must be very distinctly understood that I hold no mandate for the Council. These are only independent and crude suggestions which may lead to something better.

But we have a large field before us. We may assist the Society of Analysts in verifying analytical standards and promoting general methods in commercial analysis, and do away with the terrible names of "high and low chemists." We ought to help Professor Armstrong in his praiseworthy desire to reduce and classify the great bulk of chemical literature, and to secure monographs on special subjects, bringing this special knowledge up to date.

Every movement in technical education must be carefully watched and promoted by this Society. The Council have

therefore appointed Messrs. Prentice and Spiller, who will worthily represent us at the Technical Education Conference.

We may even some day get a curriculum, or some other substitute for pass examinations, doing away with crammers, and rearing men who will do us credit in the future and not in the past, who will be living and not stuffed.

Then we may assist commerce in such matters as the patent laws, for which we hope to secure a Royal Commission: then we may ascertain why it is possible under our present system to patent so many absurdities and impossibilities, and why foreign patents may be taken out in this country, not to introduce a new and valuable manufacture, but, by not working it, to keep it out.

We have got a select committee to consider the flash-point of mineral oils, and we shall watch its proceedings with interest. The Adulteration Act is not all that is required; food and drugs ought certainly to be separated in a new Act.

We may perhaps induce carriers to understand that dangerous goods are not rendered safer by being packed all together, but, on the contrary, often become more dangerous.

We may object to the serious way in which we are handicapped by not being allowed the use of pure spirit duty-free. Our President-elect may be able to help us here.

We might even some day venture to put a spoke in the wheel of those professional humbugs who induce credulous people to invest their money in schemes for making real silver out of quicksilver, or gold out of Dutch metal.

But perhaps this is too much to expect, for

"The world of fools has such a store  
That he who would not see an ass,  
Must bide at home and bolt his door,  
And break his looking-glass."

Now my first difficulty arises—the choice of a subject for the next part of this address.

My accomplished predecessor gave us an eloquent review of the progress of chemical industry during the last 50 years. I need not bring that up to date, for it is done in the Journal, but I was tempted to a prophetic view of the progress for the next 50 years. Chemical industry, however, consists of hard facts and stern realities, and is just one of those uncertain prospects where you should never prophesy unless you know, for it does not leave much to the imagination, except sometimes the profits. Then I could not estimate the possible future development of the microbes, for if they only kept up their present rate of progress, it seemed possible they might become the directors of the company, or the heads of the firm, and we the humble workers. For these minute bodies, whose deficiency in size is amply made up by their prodigious number and immense powers of reproduction, were bakers, brewers, and wine-makers long before we knew anything about fermentation or about them, but now we know they are constantly working with us or waging war against us. We thought that chemical industry could have nothing to do with living organisms, and now we find that many of our great manufactures are entirely dependent on them. But it is not to be always so; the accomplished French chemist Berthelot gives us a different view of the sweet bye-and-bye. In addressing the chemical manufacturers of Paris, he predicted our position a century ahead.

He said that in A.D. 2000 all locomotion will be aerial; chemical engineering will dig with diamond spades wells 4,000 metres deep, from which hot, pure water, free from microbes, will drive all the machinery on earth. No coal will be raised; there will be no agriculture, no animals reared, nor vegetables grown for food. All this will be made in the laboratory. Carbon from carbonic acid, hydrogen and oxygen from water, and nitrogen from the air.

Man will go about in bliss with "his small tablet of hydrogen, his crumb of synthetic starch or sugar, his small vial of aromatic spices, his mite of fatty matter, all manufactured economically and plentifully, independently

of season or climate, and all free from the microbes that now originate epidemics and war on human life."

The menu does not sound attractive to our grosser natures, though it may be suitable to the toothless, hairless, æsthetic spirits of that day, with the minute stomach and colossal brain; that halcyon time when the President's address will be actually more attractive to the then over-learned members of this Society than the annual dinner, and it will be a very poor one if it isn't. How the gigantic athletic female senior wranglers of that day will look down on these poor male scraps of humanity. But what will the "harp of thousand strings" be like in those days? Will there be any smoking concerts, and will they really care at all for the "warm precincts of the cheerful clay"?—with my best apology to the author of the Elegy.

But is this the way in which we are to continue our manufactures, when, having refused to listen to the excellent advice of Dr. Mond, and make the best use of our coal while we have it, we have gone on with our reckless extravagance, until we find our industries banished to the great coal-field of China? Has not boring into the earth, even at ordinary depths, been often found a trifle risky? How about the petroleum well at Baku, which blew out the heavy boring-tools and ran for four months before it could be capped, and ejected 100,000,000 galls. of oil, value 1,000,000*l.* sterling? or another in which the height of the column was 250 ft. and the pressure 200 lb. on the inch? Subterranean fires are not easily dealt with, and our volcanoes have not yet been controlled. However, Vesuvius and Etna are convenient for experiment; why not begin by putting bridles on these and drive them in double harness?

Coal will no doubt be further economised, and more power is yearly obtained from it, but there is still much to be done, especially in gasifying it for fuel; when it is exhausted no more can be got, and peat, if utilised, will not last us long; but petroleum may be continually produced if some theories of its formation be correct.

Electricity can never be properly called a prime mover as long as it depends on coal, but perhaps it is not hopeless to find some chemical reaction that may enable it to stand by itself.

Then there are other forces; there is the heat of the sun, which would take us to the desert of Sahara.

The waterfalls, which would remove us to those countries where "desperate rivers go about a-begging folks to dam 'em."

The wind. Scotland might have a look in here, for though we never make any use of this force, we have plenty to spare. Then we have the force of the rivers, the tides and the waves; the power of these may be seen at Wick, where they have tried their strength against our engineering Canutes and beaten them.

This reminds me that none of my predecessors have touched the boundless ocean; all that is left to me. I cannot grumble at any want of material, for even the land it covers is almost the only and by far the largest *terra incognita* to us; in fact, they have left me all the water, and three-fourths of the land as well. Unfortunately it is difficult of access, and that is a great difficulty. Our professional brethren may easily find iron in the sun's atmosphere, but if we are called upon to work it, we have to get there. No doubt it would be an advantage to have it in a state of vapour, but the difficulty of keeping a cool head would be insurmountable to the average chemist; of course I except Professor Dewar, who deals specially in frigidity, and is equal to anything in the way of force. A German chemist has proved to his own satisfaction that the moon is composed of iodine; it is difficult to disprove it, but if he had to work it, we should soon know. As O. W. Holmes says, "If a man asserted that the moon is a green cheese coagulated from the milky way, I would be puzzled, but if he offered to sell me a ton of this same cheese, I could sample it before I purchased."

That is where the theorists have the pull over us.

For the industrial chemist is paid only by results, often in inverse proportion to his ability; e.g., it may pay him better to boil down salt or old horses than to make alkaloids, though it may not demand so much chemical skill.

I do not intend to take the Society to sea, though there is no fear of the internal tosy turydyon which prevents the enjoyment of some, as its capacity for absorbing information is so great that it would not be likely to reject mental food of any kind, or leave it undigested under any circumstances.

I wish I could take up this great subject; it is such a grand solution of everything, though rather dilute; but the Chemical Society has made such a specialty of solutions, and spent so many evenings upon them, that it would be unfair to deprive them of almost the only one they have not yet investigated, especially as it is a pretty large order, and may keep them going for another century.

The subject would be particularly appropriate here—the scene of the great labours of Dr. Murray and Mr. Irvine, who are still working at the Scottish marine station for scientific research at Granton, and through whose kindness you will have an opportunity of visiting the only sea laboratory of the North, where the results of the "Challenger" expedition are being worked out, and many new results of their own added to the investigation.

I can only refer in passing to some.

They find that sea-water is alkaline from dissolved calcium carbonate, of which it contains 16 tons in a pure mile 100 fathoms deep; that the sea-bottom over 51,859 square miles contains 76.44 per cent. of this salt; that whereas river-water has 10 times the proportion of calcium carbonate to sulphate, in sea-water the proportions are exactly reversed. They have shown, by placing them in artificial sea-water, that the crustacea can extract the calcium carbonate to form their carapace from calcium in the form of sulphate, silicate, and phosphate; that the carbonate is derived from the sulphate by reduction into sulphide. They find that manganese nodules are constantly forming in the Firth of Clyde and other places. These gentlemen have not yet started a marine chemical industry, but it is not for want of material; and many other of their researches are most interesting to marine chemistry. No analysis can give us any idea of what the ocean really contains. If we admit that all the elements are partially soluble in a large proportion of water, what metal may not the ocean or its deposits contain, either dissolved from its vast bed or washed down by the great rivers. Silver has been found in the proportion of 1 centigramme to a cubic metre, and it has been estimated that 200,000 tons of it are there ready for some enterprising metallurgist who is fond of the small rupee to extract it. The presence of gold has not been satisfactorily proved; it was expected it might accumulate in the copper-sheathing of ships, and Messrs. Muntz obliged me with specimens of old sheathing, both copper and Muntz metal. Mr. Inglis, who kindly examined these for me, found both gold and silver, but not in larger proportion than usual.

The results were, per ton—

	Copper Sheathing.	Muntz Metal.
Gold.....	2 dwts. 21 grs.	1 dwt. 15 grs.
Silver.....	4 oz. 12 dwt. 9 grs.	5 oz. 3 dwt. 12 grs.

Besides the rich food-harvest of the sea, which costs us nothing but the taking, it is our only source of whalebone, spermaceti, and fish and blubber oils, and even the whales have been utilised in making extract of meat of peculiar flavour. It was at one time almost our only source of potassium, sodium, and magnesium salts, and of chlorine, bromine, and iodine. Dartnall has shown that the relation of bromine and chlorine is constant, 0.34 to 100. The chlorine amounts to 1.9 per cent., the bromine to 0.646 per cent. Bromine is easily detected, but iodine is very difficult of detection, as the proportion is only 1 in 291,000,000 according to my results. By the evaporation of 3,399 lb., or over a ton and a half, of Atlantic water, and crystallising out the salt, I obtained 123.5 oz. of a dark viscid liquid, of 1,352 sp. gr. From this liquid, with much difficulty, the specimen shown was extracted; probably no audience has seen it from this source before. The salt beds of Cheshire

containing neither iodine nor bromine, but the water of Wexford Spa, in Wexfordshire, is rich in both, containing 4.07 parts per million of bromine, and 5.21 of iodine.

But we can only "play on the sea-shore while the vast ocean of truth lies undiscovered before us." I can only speak of the fringe of the subject, and the fringe of the ocean is seaweed, and a lovely fringe it is in some places. Most of the marine products, fish, shellfish, and sponges, contain traces of iodine, the latter are rich also in bromine.

Our principal seaweeds are the fuci and the laminaria. In the Falkland Islands some seaweeds attain a gigantic size and length—one, the *Macrocystis Pyrifera*, extends to 1,500 feet. In the Gulf Stream, or rather surrounded by it in mid-Atlantic, a remarkable fungus grows—*Sargassum bacciferum*, forming what is known as the Sargasso Sea.

Some of the algae are largely used for food in China and Japan, but little in this country. We neglect what, no doubt, is a wholesome diet; and, unlike the fungi, there are no poisonous species.

The only well-known products are from the gelatinous species, some of which yield a gelatin of great setting power; these are the *Gelidium cornutum*, from which the Japanese isinglass is made; the *Eucheimia spinosa*, an Australian species; and the *Chondrus crispus* or carrageen, a valuable food, not so much used as it should be. Japanese isinglass was introduced 30 years ago, but the jelly is of too high a melting-point to melt in the mouth.

These gelatinous species contain no iodine nor algio, neither does the sea-grass, *Enteromorpha compressa*, though when dry it has a very strong odour of the sea.

Potash salts are the only commercial salts extracted from seaweed, but it always contains also those of magnesium. Professor Henderson has recently discovered traces of rubidium in these salts.

The fuci, which are not utilised now, at the beginning of the century were burned to supply the sodium carbonate which was used in the soap and glass works of Glasgow and Dumbarton up to 1845. I cannot ascertain what it cost from this source; it could not have been less than 100*l.* per ton, but they did not use so much soap and glass then. There was a large chemical work in the island of Barra, where it was said 80,000*l.* were expended and lost in making soap from kelp.

However, no more valuable book of reference could be compiled for applied chemistry than a dictionary of failures, if we could only get someone sufficiently qualified and courageous to undertake it. We are all grateful to the pioneer who shows us the way to the gold mine, and we ought to be equally grateful to the watchman who warns us away from the bog, the precipice, and the thief, which are much more common. Such a book would be a very large one, and many of our most successful men could write good chapters in it. Indeed, it has been said with truth "that the failures of some are eternities beyond the successes of others," and we all know that a retreat is always a difficult strategic movement.

There are always difficulties in the way: you may have difficulty of access to, or scarcity of, raw material; you may produce more than you can sell; or you may produce something new, for which there is no market.

You need not go outside Scotland if you wish to be inaccessible; it would take you longer to go to St. Kilda and back in the winter than to the centre of Africa, and there is no post and no telegraph, though it would make an excellent and much-wanted meteorological station. My own personal experiences in another inaccessible island in the Hebrides over 30 years ago would be interesting and amusing now, had I time to relate them; there was no chemical engineering in those days, and the modes of travelling very primitive, and the erection of works extremely difficult. Many a chemist, after perfecting all his arrangements for production, must have wished that his product was like Hodge's razors, "made to sell."

The commercial applications of iodine outside of medicine are of little importance, but I will refer to some. In medicine I only refer to iodoform, so much used for application to wounds, because this remarkable substance, with its peculiar and persistent odour, contains 96.8 per cent. of iodine, which cannot be applied to the skin without inflamma-

tion, and which is so entirely different in appearance and properties. Many attempts have been made to find an efficient substitute for this body without the odour, but none with similar properties and with anything like the same proportion of iodine, and the goal is still open. The iodine colours exhibited are mostly sodium salts of iodo- or iodo-bromo-fluoresceins.

It is used in the precipitation of gold and silver from weak copper ores treated in the wet way, and I am indebted to Mr. Inglis for some pretty specimens illustrating it.

Iodide of antimony and other iodides have been patented by Mr. Fawsitt, for the vulcanisation of india-rubber, especially for very elastic goods, such as wading boots. The reaction has not been yet explained, but the advantages are, that the process is much shortened, and the temperature required is so low that delicate fabrics are uninjured. This is shown in one of these fabrics, and in a pair of fishing boots which have been exposed to the heat and light of the Chicago Exhibition, and are as good as ever.

One of the little-known compounds of iodine is the iodo-mercurate of copper,  $\text{HgCuI}_4$ . It is not mentioned in ordinary text-books, though first described by MM. Willm and Caventon in 1872. It was patented by H. Crookes some years ago as a means of testing rise of temperature, but has not been used. It is simply prepared by adding solution of cupric sulphate to a boiling solution of Meyer's reagent; part of the iodine is liberated, and a black precipitate thrown down, which becomes bright scarlet on cooling.

At temperatures of about 150° F. this becomes black, and regains its colour on cooling. If painted on a bearing, it at once shows any heating long before it can do mischief.

In marine engines, where there are so many bearings, and some difficult of access, this should be useful.

Many mills also have been burnt down from this cause, and many patents taken out to indicate heating, but none so simple. The temperature of change can be altered by varying the ingredients. The colour is very like that of post-office red, which can be painted on in alternate slips. I have a tin case so painted, and when filled with boiling water the effect is at once seen.

I will now describe a new product, for which no commercial application has been found.

Hitherto the ash of seaweed only has been used, as if we employed oak and mahogany for fuel instead of making it into furniture. Nothing has yet been done in utilising the seaweed itself, although large quantities of the fuci might be obtained. Some products have been prepared, such as mannite and acetic acid, of which specimens are shown. Mannite is often seen on the frond of the laminaria as an efflorescence, and is probably the result of fermentation. Acetic acid was obtained by Stenhouse, by allowing the fucus to ferment in the presence of lime.

The larger algae are composed of a cellular fabric which amounts in the air-dry weed to about 10 per cent., and to which the name of algulose has been given. It hardens into a tough mass, easily turned, and quite permanent. The other important constituent, besides the salts, is about 20 per cent. of an insoluble albuminous substance to which the name of algin has been given; the remainder consists of mucilage, dextrin, and water.

I shall only allude to some of the prominent properties of this substance. Algin or alginic acid is a nitrogenous organic acid, soluble in all alkalis, replacing carbonic acid from the alkaline carbonates, even in the cold, and forming definite gelatinous salts, all of which have been described. It is very insoluble, especially in acidulated water. It resembles albumin, but is not coagulated by heat.

It differs from gelatin in giving no precipitate with gallo-tannic acid; from gelose, by not gelatinising on cooling; from starch, by giving no colour with iodine; from dextrin, from gum arabic, and pectin, by insolubility in dilute alcohol and dilute mineral acids, and by containing nitrogen.

The alginates of sodium, potassium, lithium, and magnesium are all soluble, forming very viscous solutions, having about 14 times the viscosity of starch. A 2 per cent. solution is at once coagulated and rendered semi-solid by a dilute mineral acid, and a 5 per cent. solution will scarcely pour.

The solution is coagulated by alcohol and acetone, but not by ether or glycerin, and by all the mineral acids except boric and arsenious acids.

Citric, lactic, oxalic, and picric acids all coagulate it, but acetic, butyric, tannic, carbolic, gallic, benzoic, pyrogallie, and succinic do not affect it.

It is precipitated at once by lime and baryta-water, insoluble alginates being formed. Magnesia, however, when added to alginic acid, combines with it, and these two very insoluble substances dissolve together in the water, forming a soluble salt.

Nearly all the metals are precipitated but not mercuric chloride—another singular distinction from albumin; mercurous salts give a white precipitate.

It is not precipitated by chlorine, bromine, nor iodine, nor by potassium silicate, chromate, and ferrocyanide.

The metals are very completely precipitated from their salts, forming gelatinous masses, some of which are soluble in ammonia; these are aluminium, iron, copper, nickel, cobalt, zinc, cadmium, chromium, manganese, tin (stannous), uranium, and platinum.

These all, on evaporation, form films insoluble in water.

Copper-ammonia alginate contains 17 per cent. of copper, as compared with cupr-ammonium, which only contains about 2 per cent. in solution.

The aluminium alginate is also soluble in caustic soda, and the solution, which is quite neutral, on evaporation dries to a film quite soluble in water.

Stannic, arsenic, and antimony alginates are also soluble in ammonia, and on evaporation yield films soluble in water.

Strontium alginate is also soluble in ammonia, which on evaporation becomes insoluble in water.

The alginates of barium, calcium, lead, and bismuth are all insoluble in ammonia.

Silver is only precipitated in strong solution, and then incompletely; it is soluble in ammonia, but on evaporation it dries to a red film with a brilliant silver mirror surface.

Ordinary sodium alginate or soluble algin dissolves perfectly in cold water, but the solution requires time; it has the advantage over gelatin of keeping indefinitely. It behaves exactly as gelatin does with potassium bichromate, the film becoming insoluble on exposure to light.

Alginic acid in an insoluble film form is easily coloured, and it dialyses well. It combines with the vegetable alkaloids or quinine, and also with aniline and chinoline and toluidine, forming soluble films.

Ammonium or sodium alginate, if mixed with one-third of shellac dissolved in ammonia, forms a tough film, which, by passing it through a weak acid bath, becomes a tough insoluble sheet. Many resins and oils can be combined with algin in this way. From the insolubility in acids, phosphoric acid can be easily separated from insoluble phosphates of calcium, iron, and aluminium by dissolving them in hydrochloric acid and precipitating with sodium alginate, the phosphoric acid combining with the sodium.

A variety of insoluble compounds may also be obtained by precipitating an insoluble alginate with an insoluble phosphate, borate, or silicate. Some of these compounds resemble bone, calcium alginate particularly.

Many colours are at once precipitated by sodium alginate, the alginic acid forming a mordant.

In fact one of the disadvantages of this peculiar substance is the ease with which it is precipitated, and another is its great viscosity, which prevents workable concentrated solutions.

In bringing this remarkable substance before you, I have only lightly drawn the main threads together of a subject in which a large amount of work has been done, in a small and unremunerative corner of chemical industry; but it is better to have worked and lost than never to have worked at all; if only as a humble pioneer "axing the way" to make it easier for the army of progress to follow.

One of the great advantages of these meetings is that they bring together for a few days members who work in so many different fields that their suggestions to each other are most valuable, and more particularly because they are not working in the same groove—the groove which we all drop into, more or less and sooner or later, in spite of

ourselves. Then we can always claim their sympathy and encouragement to all who try to add something to the general stock of knowledge, however small it may be. That encouragement which goes so far towards preventing a faint worker from coming to think that his mis-directed energies have been spent in vain.

"Letting down buckets into empty wells,  
And growing old with drawing nothing up."

and rather encourages him to be

"Still achieving, still pursuing,  
to "learn to labour and to wait."

I leave this chair to my able successor, in the full assurance that "Men may come, and men may go," but the Society of Chemical Industry will flourish in perpetual youth, and scientific research will more and more cover the ground of the chemical manufactures of this country.

Professor F. E. THORPE, F.R.S., President-elect, said that the pleasant duty had been placed upon him of expressing to their President their appreciation of the instructive and interesting address which he had just given them. Those who knew the President were thoroughly prepared that the address should be instructive and interesting, but he was quite sure that, whatever their expectations might have been, they had been realised to the full. He could only say, as a measure of his appreciation, that the address was characteristic of Mr. Stanford, and that it was worthy of him. He had ranged over a great variety of topics, some of which were very tempting, and upon which he dared say, some of them might like to dilate at some length. Time, however, pressed, and therefore, beyond making one or two very slight observations, he would not inflict himself further upon them. Some allusion had been made as to the necessity for the preparation of an index of the publications, in their various forms, of the Society. It was perhaps a very small matter in one sense, but not in another. It was a most important one, but he must confess it had struck him rather forcibly that a Society such as theirs—which was very largely in the hands of business men, of practical men, to whom time was perhaps a more primary object than it was to the student—should have delayed so long in a systematic ordering, so to say, of the subject-matter of their publications. He wished to give, on the basis of his own experience, a slight word of warning. They in the Chemical Society had within recent times set themselves to the accomplishment of a similar task, and he assured them that it was a task which did not become easier by being the longer delayed. He would therefore earnestly press upon them, before it was too late, to take that matter in hand, and by the rapid and systematic publication, at periodically short intervals of time, bring, in a digested form, the valuable information of the Journal within the ken of all their members. Mr. Stanford had practically ranged over every department which chemical industry touched. He had made some allusion to the cosmopolitan character of their work, and he had dealt, with all proper emphasis, on the fact that they were now bringing within their fold not only English-speaking chemists, but chemists from all parts of Europe; in fact, wherever chemistry was taught, or wherever it had a practical application, from China to Peru, from Japan to America. He had also dwelt upon the extraordinary example which was afforded them by a very small Swiss canton, in the extraordinary thing they saw at Zurich, and he had made use of a phrase which he ventured to say, would become classical, that they "ought to thrust their national heads into their national pockets, for they were big enough, if they were not prepared to put their hands there." Some of them had ventured to think that that national pocket might undergo a process of shrinkage; but if they thought that the national genius of this country was the better for the publications of that Society, which was rapidly coming to the forefront as a kind of focus of information, they might take credit that they were doing for chemistry, and particularly for applied chemistry, much the same work. They ought, he considered, to stand in the same relation to the instruction and the practice of

chemistry, as they did in the diffusion and inculcation of knowledge through the instrumentality of their Journal. There was just one aspect of the extremely interesting exhibit which had been shown there, and which was so entirely bound up with Mr. Stanford that he should like to make one reference to it. Mr. Stanford had identified himself with the investigation and practical application of that most interesting substance alginic acid, and he had said something about the useful purpose which a Society like that served, in bringing together ideas from every department of chemical work. Now, it had struck him very forcibly, during the account which Mr. Stanford gave of the purposes of that remarkable body, that it would have a very considerable future before it in a certain department of scientific chemistry. He had alluded to the part which the Chemical Society had played in a theoretical journal on the subject of solutions. He himself had furnished an admirable illustration of how those substances might subserve their interests in the further development of that particular subject.

Mr. HORACE T. BROWN, F.R.S., seconded the motion, which was agreed to unanimously, and the President returned thanks.

#### APPOINTMENT OF AUDITORS.

Dr. J. CLARK proposed, Dr. J. B. Readman seconded, that Theobald Bros. and Miall be appointed auditors at a fee of ten guineas. This was agreed to.

Professor CRUM BROWN, Edinburgh, proposed the election of Mr. E. Rider Cook as the Society's representative on the Board of the Imperial Institute. He might, perhaps, be allowed to say a word upon another matter, and that was, the University authorities would be very happy to see any fellows or members of the Society at the chemical laboratories in the New University Buildings. Those of them who were interested in laboratories would, he dared say, see something of interest to them there.

Mr. R. IRVINE, Edinburgh, seconded, and the motion was agreed to.

#### NEXT YEAR'S PLACE OF MEETING.

Professor SMITHELLS, of the Yorkshire College, invited the Society to visit York-shire in 1895. It was his very pleasing duty, he said, and his last act as Chairman of the Yorkshire Section, to ask the Society to honour them by visiting Yorkshire next year, and by holding their meeting, in all probability, in Leeds. In endeavouring to get them to accept that invitation, fortunately he had not to try to persuade them to leave Edinburgh, because they were bound to leave Edinburgh. He need not enlarge upon the claims they had in Yorkshire. They were the youngest Section of the Society, and on that account they were pleased to receive the solicitude of their parent; and they were extremely central so far as railway communication was concerned. In Leeds they had a great variety of chemical industries, and they had, in Leeds, on the whole, from an industrial point of view, a greater variety of industrial manufactures than they would find in almost any other town in England, and perhaps in Scotland. Apart from that, they had educational institutions of all kinds, ministering very specially to chemical industry, and he was sure that on behalf of all, and particularly of the York-shire College, with which he was connected, they would offer them a hearty welcome. Another claim they might put forward was that Leeds, although not in itself of great attraction, was situated in a very beautiful neighbourhood. If they decided to accept that invitation, it would be a source of great pleasure to them in that district to have the Society under the presidency of one who had been so closely associated with Leeds in the past, and whose name was very highly honoured in that neighbourhood.

Mr. T. FAIRLEY, Leeds, said he had very great pleasure in seconding the invitation. They were a comparatively young and inexperienced Section, but what they wanted in knowledge and experience they would try to make up in zeal and endeavour to make the meeting a successful one. They had no very great succession of chemical industries

in Yorkshire, such as they had in some places upon the Tyne, the Clyde, the Mersey, or the Thames, but their river had a yield in colour and smell as large as any river in the United Kingdom.

The invitation was accepted.

On the motion of Mr. Irvine a vote of thanks was accorded to Mr. Stanford for his services in the chair and as President, and the proceedings terminated.

#### VISITS TO WORKS AND PLACES OF LOCAL INTEREST.

After the morning's business was concluded, the first excursion was made by coach to Roslin and Rosslyn Chapel.

##### 1. ROSLIN AND ROSSLYN GLEN AND CHAPEL.

###### *Excursion A.—Leader: Robt. Irvine, Esq.*

A large party set out by coach to inspect these attractive points of interest. Roslin is delightfully situated about seven miles from Edinburgh, and forms a centre of classic interest immortalised by Sir Walter Scott, and perpetuated by the poet Drummond of Hawthornden. Rosslyn Glen is the most romantic and picturesque spot anywhere in the Edinburgh neighbourhood. The Castle was the seat of the St. Clairs, Earls of Orkney. It stands on a rock overhanging the Esk. Three victories were achieved in one day in 1303 in its vicinity by the Scottish forces over the English. Rosslyn Chapel is a brilliant example of Gothic architecture. It was founded in 1446, and consists of a chancel and transept, and is divided into centre- and side-aisles by rows of exquisitely sculptured pillars supporting Saxon Gothic arches.

##### 2. THE PAPER MILLS OF MESSRS. ALEX. COWAN AND SONS, LTD., AND JAMES BROWN AND CO.

###### *Excursion B.—Leader: Dr. Stevenson Macadam.*

At the same time that the party for Roslin started, a somewhat smaller one also set off by coach, under the leadership of Dr. Stevenson Macadam, for Penienik. Since the important matter of the prevention of river pollution by the two paper mills in question is under the immediate supervision and inspectorate of Dr. Macadam, it may be anticipated that the interest of the visitors would be fully satisfied by the able demonstration given. In Messrs. Cowan's Valleyfield Mills four paper machines are employed for the manufacture of about 100 tons per week of the higher qualities of writing- and printing-papers, the materials used being chiefly rags and esparto grass, with also a small quantity of wood-pulp. The treatment of the waste esparto liquors is carried out by processes of filtration upon ash filter-beds, settling the sludge, running off cleared liquors, &c., the final effluent being, for such an effluent, surprisingly clear, non-alkaline, and only containing 100 grains of solids per gallon at the outside. Dr. Macadam is justly proud of the success of his remedial process, and especially as the result has proved to have repaid the labour and expense, and to be yielding a small profit. The settled sludge already referred to is filtered, pressed into blocks, or finally utilised for the production of an inferior paper.

The visitors who enjoyed the privilege of hearing Dr. Stevenson Macadam's demonstration of the working of the remedial measures against river pollution, and of the entire process of paper manufacture, both at Messrs. Cowan's and the Esk Mills, will not soon forget the lucid manner in which the descriptions were given.

After the inspection of Messrs. Cowan's mills, the party was most kindly entertained to tea and refreshments at the romantically situated residence close to the mills, by Mrs. Cowan, assisted by her daughters. It was a typical example of homely and hearty Scottish hospitality.

The Esk Mills of Messrs. Jas. Brown and Co., Lim., are situated in the beautiful valley of the North Esk, and the raw material here employed is also esparto grass, from every two tons of which about one ton of paper is manufactured. Processes are carried out in connection with the remedial

measures for recovering the alkali used, and whilst 80 per cent. of the latter is recovered at Messrs. Cowan's, no less than 83 per cent. is returned in the Esk Mills. This Dr. Macadam puts as equivalent to getting the alkali at half-price. In the Esk Mills a multiple effect evaporator (Yarvan system) has lately been introduced for promoting efficiency and economy in the soda recovery. On the return journey Dr. Macadam, determined if possible to beat any other record, promised the party a participation of the visit to Rosslyn Glen and Chapel if by any means possible; this promise was carried out most successfully, the party arriving in Edinburgh on the return journey at about 8 o'clock, and comfortably in time for preparing for the event of the evening, *à wit*, the

#### RECEPTION AND CONVERSAZIONE.

The reception and conversazione took place in the Museum of Science and Art adjoining the University, in Chambers Street. Here the members and friends, with their ladies, were received and welcomed in the magnificent hall by Bailie Dunlop, as representative of the Lord Provost of Edinburgh, the Magistrates and Council. The galleries and entire suite of exhibition rooms were thrown open, and whilst some of the company inspected the objects of interest, zoological, geological, and antiquarian, in this fine museum, others listened to music finely rendered by two military bands, notably that of the celebrated "Black Watch." Refreshments were served during the evening in the most bountiful fashion by an arrangement in which the usual difficulty of overcrowding and congestion, was well overcome. The function altogether was perhaps the most brilliant one the Society has yet witnessed at its Annual General Meetings.

#### SECOND DAY.—THURSDAY, JULY 19TH.

A new feature was introduced at the Edinburgh meeting, in the arrangements for visiting the numerous works, &c., which had generously consented to open their doors to the visitors, viz., the furnishing of daily programmes giving every necessary item of information, issued by the chief officers, to whose untiring energy and sound judgment so much of the great success of the meeting is to be ascribed; we refer to Mr. Robt. Irvine, the Chairman of the Scottish Section, Mr. J. Stanley Muir, the Hon. Secretary, and Professor W. Ivison Macadam, the Hon. Treasurer.

##### 1. MESSRS. THOMAS NELSON AND SONS, PARKSIDE WORKS, EDINBURGH.

*Leader: David Harris, Esq.*

A party started by coach to visit the above factory, in which the following industries were represented and illustrated:—Bookbinding, Illustration and Colour Printing, Map Engraving, and General Book Work.

##### 2. MESSRS. BERTRAMS, LIMITED, ST. KATHRINE'S WORKS, SCIENNES.

The visitors here had opportunity to inspect the processes of manufacture of general machinery. Especially there was shown in operation a large wall-planing machine, working either vertically or horizontally. Along with general paper-making machinery, the members had opportunity to inspect a paper-making machine of novel construction intended for despatch to Lucknow, India.

##### 3. MESSRS. JAMES AND THOMAS USHER, PARK BREWERY, EDINBURGH.

All the operations connected with brewing were here shown in working order. Messrs. James and Thomas Usher having been so good as to make special arrangements whereby a brewing was started and conducted during the visit of the members.

This notable and extensive business dates its history from the year 1828, when it was founded by the firm

whose title it still bears, at premises situated in close proximity to George IV. Bridge. Here the brewing industry of Messrs. Usher was successfully carried on until the year 1862, when the firm erected their present large and convenient premises, the Park Brewery. The firm has made the most of every advantage attaching to their new establishment, both in position and in working resources, and the Park Brewery at the present time ranks among the most conveniently arranged and most perfectly equipped in Edinburgh. The premises comprise several large blocks of substantial buildings, with spacious yards, the whole covering some acres of ground. The buildings are several storeys in height, and are laid out upon a well-considered plan, the various structures being admirably adapted to their allotted purposes as brew-house, malt-floors, malt-stores, barley-lofts, and very capacious cellars, under all. There are also hop-stores of large capacity, and the kiln equipment is eminently efficient. All the arrangements for malting and for the subsequent conducting of the liquor through the various stages of brewing are based upon gravitation principles, and in this way an appreciable saving is effected in steam power. The processes carried out at the Park Brewery are of the kind usually associated with the brewing of high-class ales and porter in accordance with the most approved modern methods; and the mash-tuns and coppers, as well as the coolers and fermenting tuns, are all of large capacity and of the best class and construction. The brewery water is of singularly fine quality, an unlimited supply being obtained from wells on the premises; and, as the Park Brewery stands at the outskirts of the city, and upon high ground, when its site is compared with many of the surrounding districts, the water here used is of assured purity, there being no chance of pollution.

*Leader: Dr. J. B. Rouburn.*

##### 4. MESSRS. WM. McEwan and Co., Ltd., FOUNTAIN-BRIDGE, EDINBURGH.

The brewing of Edinburgh and Export Ales was shown at this Brewery.

##### 5. THE NORTH BRITISH DISTILLERY CO., LTD., GEORGIE ROAD, EDINBURGH.

Here were exhibited maltings with grain conveying machinery; the milling and mashing departments, the distilling apparatus, and the draft and pot-ale drying machine.

Lunch was kindly prepared for the visitors here.

##### 6. THE BROXBURN OIL COMPANY, LTD., BROXBURN.

The visitors started by train from Waverley Station at 9.20 in the morning for Drumshoreland Station, and thence travelled by coach to the Oil Works, where they were most cordially received by Messrs. Kennedy, Henderson, and Stewart, who subsequently acted as guides and demonstrators, the party being broken up into three groups, each of which was led by one of the gentlemen named. After the inspection a bountiful luncheon was provided for the party, and the President, Mr. Stanford, then expressed in the warmest terms, on a cordial vote of thanks, the sense of indebtedness of the large party which had availed itself of this opportunity for the great pleasure thus afforded. The following report will give an idea what that indebtedness was, and what the pleasure must have been:—

##### BROXBURN MINERAL OIL WORKS, AND THE PRODUCTS FROM SHALE.

*The Shale.*

The shale is mined in much the same manner as coal, and conveyed to the breaking-machine in railway waggons. The waggons are tipped by hydraulic machinery into the large hoppers of the breaking-machine, where the shale is broken into pieces about three inches square. It is then conveyed to the retorts in hatches containing about 12 hundredweights.

### The Retorts.

The retorts (known as "Henderson's patent improved retort") are vertical, and 28 ft. long. In the upper portion, about 11 ft. long, and made of iron, the oil is first distilled off the shale at a temperature of 900° F. The spent shale then passes downward into the brick portion of the retort, and is kept in constant motion by a roller at the bottom, which delivers it into a hopper below at any required rate. This portion is kept at a temperature of about 1,300° F. This higher temperature largely increases the yield of ammonia and permanent gases from the carbon of the shale. The hot products of distillation are drawn from the top of the retorts in the form of oil and water vapours, and permanent gas, passed through a long range of cooling pipes, and the condensed liquids, on being separated, are called crude oil and ammonia water.

The incombustible or permanent gas is used as fuel.

The spent shale, being of no further use, is stored in a large rubbish bin.

The ammonia water is distilled with steam in a special column-still, and the ammonia is passed into sulphuric acid, and sulphate of ammonia produced.

The crude oil is refined and fractionated into various qualities of oils, such as lamp oils, gas oils, lubricating oils, solid paraffin, &c., &c.

### The Crude Oil.

The crude oil is refined by repeated distillations, during which it is fractionated into products having the different gravities required, and by treatment with oil of vitriol and with caustic soda. The distillations are according to Henderson's patent continuous system.

The first distillation gives—

Green naphtha.

Green oil.

Still coke (a valuable smokeless fuel).

The "green naphtha" is treated with oil of vitriol and with caustic soda, and after another steam distillation, is ready for the market as shale spirit or naphtha.

The green oil receives treatments with oil of vitriol and caustic soda, and is then ready for the second distillation.

In the treatments the oil is stirred first with oil of vitriol and allowed to settle, when a black tar falls to the bottom, and is run off. The oil is run by gravitation into another vessel, and is mixed with solution of caustic soda. On settling, another black tar separates out. The chemicals are recovered from the tarry matters, and the residual tars are used as fuel by being injected with steam into the still furnaces (in the form of a fine spray) and burned. The recovered sulphuric acid is used for making sulphate of ammonia. The oil of vitriol used in the oil refining is manufactured by the Company.

In the second distillation the green oil is fractionated into light oils and heavy oils, the latter (heavy) containing solid paraffin. The light oils are treated and distilled several times, and are ready for the market as burning oils.

The heavy oils are cooled below the freezing point of water, and the paraffin strained out by passing through filter-presses, the two products from the filter-presses being now termed blue oil and solid crude paraffin.

The blue oil is treated and distilled, fractionated into intermediate oils—used for gas making and other purposes—and heavy oils for lubricating machinery.

The crude solid paraffin is passed direct from the filter-presses to the sweating chambers (Henderson's patent, for purifying paraffin), where it is fractionated and refined to from 100° to 120° F. melting point, and it is then known as semi-refined paraffin.

If this paraffin needs to be further refined or made pure white, the sweating and fractionating process is repeated, and the paraffin is then known as refined paraffin wax of from 125° to 130° F. melting-point.

After the sweating process, the liquid paraffin is mixed with char, settled, and then filtered through paper, when it is cooled into blocks of paraffin wax, and is ready for making into candles, night lights, wax matches, or for other purposes.

The total refined paraffin produced is about 4,000 tons per annum, the greater portion of which is made into candles at the Broxburn Works, and sent over all parts of the world.

The candle works are extensive, and capable of making from 14 to 16 tons of candles per day.

The soft paraffin, melting-point 100° F., is called match paraffin, being now used for dipping the ends of the wood matches instead of brimstone, and also for burning in miners' lamps, and various other purposes.

The average throughput of shale is about 1,300 tons per day, the Broxburn seam yielding 32 gallons of crude oil and about 46 lb. sulphate of ammonia per ton, while the lower seams of the Roman camp shales yield about 20 gallons of crude oil and over 72 lb. sulphate of ammonia per ton.

Over 11 million gallons of crude oil are refined annually.

The works and mines cover an area of 250 acres, and there are about 1,700 men and boys employed.

The following samples are to be seen in the show-case:—

BROXBURN SHALE, from which the following products are made.

7. MESSRS. JOHN FORD AND CO., HOLYROOD GLASS WORKS, EDINBURGH (Glass Manufacturers to the Queen).

Leader: John Ford, Esq.

These works are the oldest and most complete in Scotland, having been originally built at the beginning of the century, in succession to those of a similar description, carried on simultaneously for a time, at Portobello; owing to locality and the enterprise of the firm, a great variety of work has been and is done, comprising every description of flint glass for scientific, lighting, domestic, and decorative purposes.

The richest quality of lead glass is generally made, and has a world-wide reputation for quality, colour, and brilliancy; all the chemicals for this and other special glasses are obtained from England, France, and Germany.

The furnaces and workshops cover a considerable area, and have been added to and improved from time to time. The principal furnace is stoked by a Frisbie feeder, and consumes from 3 to 4 tons of coal per week; splint coal is in favour. This furnace has been burning for ten years, and can melt 8 tons of glass at a time. The premises for the operations of cutting, sand-blasting, engraving, etching, &c., have been specially constructed for efficient production. The machines and showrooms are stated to contain the largest and most varied stock in Great Britain.

The most magnificent engraved service of table-glass has just been completed for H.R.H. the Duchess of York, the representative pieces of which were commanded by Her Majesty the Queen to be submitted at Balmoral. The work occupied 12 months, and has been carried out by the highest class of artists, either trained by the firm, or having a long term of service under the direction of Mr. John Humphrey Ford, upon whom have rested the whole details of design and manufacture. The firm is presently engaged on some work for H.R.H. the Princess Beatrice, and H.E.M. the Empress Frederick of Saxony, who has graciously indicated by her own drawing the line of design which is to be followed.

Many distinguished visitors, including H.R.H. the Prince of Wales, have seen the works, which have always been carried on by the Ford family; four generations have taken part at Holyrood.

Mr. John Humphrey Ford, with his brother-in-law and partner, Mr. William Ranken, assisted by the staff, were prepared to show visitors over the works during any of the days of the conference, without restriction.

#### 8. MESSRS. WILLIAM YOUNGER AND CO., LIMITED, ABBEY BREWERY, EDINBURGH.

The visitors had the opportunity here presented of seeing over one of the oldest established breweries in the country. Mr. J. Younger, Esq., one of the directors, acted as conductor and demonstrator.

#### 9. THE EDINBURGH GAS WORKS, CANONGATE, EDINBURGH.

For those interested in the gas manufacture an opportunity was here afforded of inspecting an economic mode of firing gas retorts, the Siemens system being employed, and a set of 16 retorts being worked by one producer.

#### 10. THE GLASS WORKS OF A. D. JENKINSON, OF ABBEYHILL.

An opportunity was here afforded of witnessing the manufacture of ornamental glass, Venetian and Art glass.

#### 11. VISIT TO THE FORTH BRIDGE, AND GARDEN PARTY, on the Invitation of MESSRS. A. B. FLEMING AND CO.

At 1.40 p.m. a large party started from the Waverley Station by train for Granton, where a steamer was in attendance to convey the members and friends to view the Forth Bridge. The weather being exceptionally bright and clear, fine views were obtained, and the great bridge itself was seen under the most favourable conditions. Luncheon was partaken of on board the steamer. Later on in the afternoon the steamer returned to Granton, and then to Royston, where the party disembarked and ascended the hill to the residence of Mr. A. B. Fleming, which is most beautifully situated, and where all the preliminaries for an enjoyable Garden Party had been arranged by the hospitable host and hostess. A Reception was given by Mr. and Mrs. Robt. Irvine. Subsequently an inspection was made of the following branches of manufacture in the extensive factory of A. B. Fleming and Co.:—Lamp Black, Printing Inks, and Solidified Oils. It may be interesting to record here that the patent solidified oil is the invention of Mr. Robt. Irvine, the Chairman of the Scottish Section, who is also the chemical adviser of the firm. This oil is not sensitive to either heat or cold, but under all circumstances maintains its uniform consistency. It is consequently unaffected by climatic influences. It is specially recommended for use in the shafting and journals of mills, there being no danger

of leakage or saturation of walls or woodwork. Among other specialities should be mentioned Messrs. Fleming's bloomless vegetable and mineral mixing oils, for which it is stated there is a great demand. An opportunity was also afforded of inspecting the Marine Station at Cathline Park, after which the party returned to Edinburgh by special train at 6 p.m.

#### 12. THE LOTHIAN COAL COMPANY, LIMITED.

A supplementary opportunity was afforded the visitors of inspecting the colliery of the above Company, and Messrs. Jas. A. Hood, Jas. Hamilton, Jas. Simpson, and Thos. Webster, Esqs., undertook to meet and conduct the party over the works.

Coal has been worked at this colliery for a great number of years, and the daily output averages about 600 tons. The coal produced is used for both house and steam purposes. The plant inspected comprises air-compressing machinery, compressed air being used for the purpose of driving coal-cutting machines and pumps underground. Dynamos for driving pumps underground and for lighting. Guided ventilating fan and engine.

At the brickworks, which are extensive, the plant includes two brick-making machines, semi-dry, which make something like 17 to 18 thousand bricks a day each. Brick-making by hand was also seen. Machinery for the purpose of manufacturing fire-clay pipes, &c. For the burning of bricks a large Hoffman kiln has been in operation for many years, and there are also kilns for burning the fire-clay pipes, &c. Machinery for the purpose of grinding clay for the manufacture of bricks was also exhibited.

#### THE ANNUAL DINNER.

The annual dinner was held in the Waterloo Hotel on the evening of Thursday, 19th July. Mr. Stanford occupied the chair, and had on his right Lord Provost Sir Jas. A. Russell, of Edinburgh; Mr. R. Pullar, Perth; Professor Crum Brown, F.R.S., Edinburgh; Mr. Chas. Dreyfus, Manchester; and Mr. Horace T. Brown, F.R.S.; and on his left, Mr. D. Howard, London; Dr. John Murray, Edinburgh, &c. Messrs. R. Irvine, Edinburgh; C. A. Fawcitt, Glasgow; and I. Tyrer, London, were croupiers. There was a large company.

The toast of "The Queen and the Royal Family" having been duly honoured,

Mr. D. Howard proposed "The Society of Chemical Industry." He said that the industry of chemistry might claim that in Scotland it had received a marvellously hospitable welcome. If they might believe certain utterances which they had heard at Burlington House, and elsewhere, they were in such a parlous state that to propose their health was a desperate task. Though he knew full well the difficulties that those comments brought in daily life, he knew also that in many ways Britons had greater disadvantages than their neighbours. They were told that their only hope of further existence was to model their works upon a certain pattern which was described, which pattern, he believed, was drawn from a particular works in Germany—a works which had had enormous prosperity, owing to the British system of patent law, which protected the foreigner to the destruction of home industry; a works which also owed its great profits to the manufacture of synthetic remedies which were inaccessible to us, on account of that strange law which some mase-line women and effeminate men had passed for the prevention of the progress of knowledge in physiological chemistry. Those were disadvantages, and there were many more which it was of no use repeating. Yet he did not despair, pessimist though he was, of the future of chemical industry in this country, and very largely because of the existence of that Society, and of the existence of the spirit which had brought that Society into existence, and which was not confined to the operations of that Society. If the industrial chemists of the United Kingdom thought it worth while to spend 3,000*l.* a year in order to inform themselves of the progress of knowledge in the matters of their business, at any rate they were not blind to what was going on; they did not shut their eyes to

what was to be learnt. So long as this spirit existed he thought they had nothing to fear; at any rate they would make it as good a fight as they could. Might he echo once more the motto that was constantly being spoken of, and yet, unhappily, not always acted upon,—“What they wanted was research.” He wanted to carry out that further than it was generally carried out. It was not alone such research as had been nobly illustrated by a past President of that Society; it was not alone the research which found its outcome in papers in the Journal of the Society. It was that same habit of mind which produced great discoveries, which was wanted in the every-day work of the laboratory. It was the same spirit of research which was required in every detail of their work, which was required to make great discoveries. He would urge it upon their juniors not to expect to be taught what they wanted, for the wisest of their teachers only taught them how to teach themselves, and if they found that what they had learnt was not what they wanted, let them not blame their teachers, but blame themselves. It was the duty of the teachers to teach them to learn rather than to teach them to know. There were no two factories alike, not even those who were working the same process and doing the same thing; every one had their own peculiarities, and the chemist was only fit to work in any and all who was not content merely to know what could be taught in the name of that mysterious entity—technical education, but had learnt the great lesson of working by himself. That was what the Society of Chemical Industry had endeavoured, by example and precept, to carry out; and, might he say, they were most happy in their present President, whose name he coupled with the toast, in being a brilliant example of carrying out, in practical life, what he had endeavoured to express in theory.

The CHAIRMAN, in acknowledging the toast, said that what was wanted was original research and not class examination. They did not want to cut down their men to a Procrustean level; they wanted to encourage them each to go higher than the rest. That was the principle which this nation had yet to learn, and the principle which must govern their Society of Chemical Industry.

Professor IVISON MACADAM, Edinburgh, gave the toast of “The Lord Provost and Magistrates of Edinburgh.” He said that the Lord Provost, when first approached, heartily promised to look after the Society; that he was not able to fulfil his promise, was due to the fact that in obedience to the command of Her Majesty the Queen he had to go south at that time. He could assure them that not only was the Lord Provost ready to welcome them, but the magistrates, and Bailie Dunlop, who took his place, thoroughly backed up the Lord Provost, and they had all been most anxious that the visit of the Society to their city should be most happy and successful in every way.

Lord Provost Sir JAS. A. RUSSELL responded. He said he must begin with words of apology for failing to keep his engagement to receive them at his own house. They had already heard the reason, and he had no doubt they would excuse him. At the time he hoped to meet them he was being introduced to Her Majesty the Queen by his old friend (Lord Playfair), whose lectures he attended rather more than 30 years ago; and he thought it rather a remarkable coincidence that at the time he ought have been with the Society of Chemical Industry in Edinburgh, he was being honoured by one who was so much connected with science. They were delighted to see the Society in Edinburgh, partly because, and largely because, they were glad to receive them, and show them their hospitality; but they also expected to derive benefit from the visit of the Society. He thought that a Society which could give such instruction as was given in the speech of Mr. Howard could not visit them without leaving permanent benefit behind. Edinburgh was largely an educational city. The Town Council had from time immemorial been closely connected with education in various forms. It had been connected with the University and with large educational trusts, and they thoroughly appreciated the vital interest of encouraging true education, and not the mere acquisition of knowledge. And he believed that, so far as in them lay,

they were anxious to further that research and the real knowledge of the advancement of science, which would, by the discovery of great ideas, lead to their application in practice, and to the material benefit of the country. Recently the Town Council came into a small sum of money, derived from the Government grant, and he was curious to see from the newspapers what was being done in other towns with that money. He found that many of them applied the grant to the relief of their pockets, by lessening their taxes; others of them applied it partly for educational purposes; the Town Council of Edinburgh passed a resolution that it should be entirely applied to educational purposes. Though they had not the numerous chimneys which were at once the source of wealth and disfigurement to other towns, they had some interest in chemical industries, and some of their neighbours had shown that they had the ability to make original researches, and to apply those researches to practical ends; and he believed that the visit of the Society would be, to those who were engaged in chemical industries, a most valuable stimulus, a means of encouraging them in their work, and a valuable means of educating the public to give their support to work dependent upon science. Mr. Howard confessed himself to be a pessimist, and evidently deplored a tax being made upon the accumulation of wealth. If there was anyone who wished to cheat the Chancellor of the Exchequer, and who wished at the same time to benefit, not only his own generation, but future generations, let such be commended to play the rôle of a pious founder. Their city had benefited by pious founders in the past; but possibly the class was not so plentiful as it was 300 years ago. Educational foundations had done an immense deal for their town, but they had still much room for similar foundations, applied with modern ideas; and if one result of the visit of the Society should be to turn the thoughts of those among them who had been prospering in the lines of chemical industry into doing something for the advancement of science, he was sure the Society would be pleased, and the city would have cause to rejoice at their visit.

Mr. R. PULLAR, Perth, proposed “The University.” He said they heard a good deal of foreign competition. He had seen a good deal of industries abroad, and he could only say that they had many difficulties there, and that if in this country they just set themselves to, and kept themselves up to the mark they should be pretty well able to hold their own. It was not a bad country this to work in; there were a great many advantages in it in many ways, but that one important point in which they could improve the business of the country was to get the very highest and best talent into it, which could only be done by providing thoroughly educated men. There was no doubt that a thoroughly good and suitable education for those who were to be at the head of industries was a good thing, and that two or three years spent at a University, or a high school, was not lost time. He thought the more technical knowledge they had the better; if they had the knowledge they should soon apply it practically. They had no better illustration of that than in the gentleman whose name he was going to couple with the toast—Professor CRUM BROWN. They all knew the enthusiasm he showed in his work, and the interest he took in the progress of chemical science as applied in the various arts.

Professor CRUM BROWN, Edinburgh, in responding, said that a great many people imagined the University to be a place where pure, theoretical, quite unworkable modes of thought existed. Practical men knew that there was not that sharp division between practical and scientific matters which the uneducated imagined. The really wise man was the man who knew what to do in an emergency, and had the strength and presence of mind to do it. Life consisted, whether they were practical or scientific, in a constant succession of emergencies. There was no difference in the way in which they worked; it was sound judgment and common sense applied; and the difference was in the particular subject to which it was applied. They wished everyone to understand that a sensible, well-educated, and intelligent man was what they hoped the University would provide, in whatever kind of teaching it practised. They

wished that truth and reasonableness should prevail, and that scientific and practical men would unite and quench that nonsense which interfered so much with their success in every walk of life. The University had just put its house in order. A good many people felt a good deal of apprehension as to what would come of it. He was not a pessimist, and he never had the least suspicion or fear of what the Commission would do, because there was nothing better in the world than fresh air and light, nor a room or an institution the worse for it. The Commission had been a most painstaking one. He did not suppose that any one of the Commissioners would say that all they had done was right, but they had done a great deal that was right, and they had put the University in a much better position than it was in before.

Mr. R. IRVINE, Edinburgh, proposed "The Guests."

Mr. T. TYRER, in proposing "The Scottish Section," said the Society had been most courteously received by the Section, and that they had received loyal service, honorary service, especially from the local Treasurer and Secretary, who had made the arrangements for the visit, and whose names he begged to couple with the toast.

Professor IYVON MACADAM and Mr. J. STANLEY MUIR, Glasgow, responded, and the proceedings then closed.

### THIRD DAY.—FRIDAY, JULY 20.

#### VISIT TO ST. ANDREWS, RIVER TAY, AND PERTH.

A special train leaving the Waverley Station at 8.55 a.m., conveyed the large party taking advantage of this interesting excursion, and consisting of about 200 ladies and gentlemen, across the Forth Bridge on the Dunfermline route as far as Inverkeithing, then towards Burntisland, passing through the woods of Aberdour. The line, in approaching the coast, has on the left the "Kingdom"—so called because of its importance during the era of the Pictish kings. On the right fine views were obtained of the Firth of Forth and the numerous islands. Aberdour was at one time the port of Dunfermline. The Island of Inchcolm lies off the coast, and contains the ruins of an Augustinian monastery founded by Alexander I. Burntisland, three miles to the east, possesses a sheltered and roomy harbour, overhung by the ancient Castle of Rosend. Further east was Kirkcaldy, the premier manufacturing centre in this part of Scotland. The next place was Dysart, two miles east of Kirkcaldy. The lauds of Ravensraig adjoin the burgh on the west. They include the old Castle of Ravensraig or Ravenshough. This picturesque ruin occupies a conspicuous position on the summit of a lofty rock overhanging the sea. The line now leaves the coast, and turns to the north, *en route* for Thornton Junction, where the line from Dunfermline joins. Proceeding eastwards the coast was again approached at Leven. While on the journey towards Largo, there were observed the three upright red sandstones, popularly known as "The Standing Stones of Lauder." On nearing Largo, a low and sandy shore was approached, which rises towards the north, and culminates in the conical and beautifully green Law. Near Crail, the line turns to the N.W., passing Kingsbarns and Boarhills to St. Andrews. Here the train stopped for one hour and a half.

The party was now shown the various points of interest in this, the most ancient University City of Scotland, under the leadership of Baulie Ritchie Welch. These were:—(1.) The West Port, the last of the old City Gates, probably built about the beginning of the 17th century. (2.) The Madras College and the ruins of the Dominican Friary, rebuilt about A.D. 1520. (3.) The Town Church. Archbishop Sharp's Monument (killed at Magnus Muir A.D. 1679). (4.) St. Mary's College, University Library. (5.) St. Leonard's Church and the remains of College, founded in 1512. (6.) The Cathedral Ruins and St. Regulus Church. (7.) The Castle, Palace of the Bishops. 8. St. Salvator's College and Church, Bishop Kennedy's Monument. He died A.D. 1478.

The train then proceeded, *via* the Tay Bridge, to Dundee, where the saloon steamer "S. Ota" was waiting.

Leaving the pier at Dundee, and proceeding up the river to Newburgh and Perth, the first object which arrested attention was the "Mar-" training ship. This excellent institution supports and educates about 100 boys.

*The Tay Bridge.*—No one can pass through the lofty spans of the new bridge without recalling the terrible disaster which occurred here on the last Sunday of December 1879. The erection of the new bridge was entrusted to Messrs. Arrol & Co., of Glasgow, from plans prepared by Mr. Barlow, engineer, London, and was begun in 1883. The work has been carefully performed under strict Government inspection, and every pier on reaching high-water mark was subjected to a rigorous test before any of the superstructure was placed upon it, these tests having been in the case of every pier most satisfactory. The estimated cost of the bridge was about 700,000*l.*, made up as follows: Piers 5 to 77, are estimated to cost 232,000*l.*; girders and parapet, 265,000*l.*; subaqueous portion of works, 32,000*l.* The diameter of the cylinders for the piers varies from 23 ft. to 17 ft. 6 in. Some of the piers have been sunk to a depth of 35 ft. below the bed of the river. Each pier consists of two cylinders. Those piers under 23 ft. diameter are 26 ft. apart; while the 23 ft. cylinders are 32 ft. apart measuring from centres. The cylinders are carried up independently above high-water mark, and are then joined by a connecting piece consisting of brickwork backed with cement concrete 7 ft. deep, and strengthened with cast-iron bearers and tiers with wrought-iron tie-pieces. Above this is the iron superstructure on which the girders rest. The superstructure is connected to the brickworks by tie-bars. The larger spans are 245 ft. and 227 ft. (that is, in the gap), and 162 ft. and 145 ft. The others are 129 ft., 108 ft., 71 ft., and 68 ft. The cylinders were tested by test-weights varying from 600 to 2,400 tons, and the tests were very satisfactory in all respects. The total length of the bridge is 16,780 ft., while its width at the level of the railway line varies from 25 to 28 ft. The width of the river at the site of the viaduct is 9,580 ft. The height to the boom of the girder at the south side is 65 ft., at centre 77 ft., at north side 16 ft. The number of spans is 85.

On the left was seen Balmerino, where stood the abbey of that name, and where rests the remains of Queen Ermenegarde, wife of William the Lion, the founder of this and the Abbey of Arbroath. Balmerino gives the title to the celebrated lord of that name, who fell a victim to the cause of the Stuarts.

A little to the west a fine view was obtained of Birkhill, the seat of the Wedderburns of that ilk, hereditary Standard Bearers of Scotland. Looking towards the north and west, Castle Huntly and Rossie Priory, together with the villages of Longforgan and Inchtutho, and the Sidlaw Hills were seen. On the left are the Ochil Hills. A little to the west the ruin of Balmabreich Castle was visible, close to the water's edge. Balmabreich was one of the seats of the Leslies of Fife, and is now the property of the Earl of Zetland. Immediately to the south and west of this was fought the battle of Black Inneside or Earnside, where Wallace defeated the English under Sir John Steward. Immediately opposite, on the north bank of the river, on the rising ground, is the village of Errol, to the west of which is the mansion-house of Errol Park, owned by Mr. W. O. Dalgleish, and to the south is Port Allen.

On the Fife side is Parkhill, a modern mansion. About halfway between Parkhill and Newburgh lies Lindores Abbey, the most interesting ruin in the locality. Among the stone coffins found here are two which were said to contain the remains of the children of David, Earl of Huntingdon, brother to William the Lion, and whose death changed the hereditary descent of the Crown of Scotland, and led to the disputes that caused the wars in the days of Wallace and Bruce. This abbey is said to have been built by Earl David on his return from the Holy Land, about the year 1178. On the left is the village of Newburgh, which has long been famous for its fruit. Directly opposite Newburgh, in the middle of the river, is Mugdrum Island,

which was originally a large sandbank formed by the confluence of the Tay and Earn. It was artificially enlarged by the planting of reeds, which retained the mud and sand brought by the tide, and now contains a fertile farm. In the wood, on the south bank of the river, are the mansion houses of Magdram and Carpow. On the north side of the river is the Pifour Brickwork. This company's first contract was for 9,000,000 bricks for the building of the Tay Bridge.

On the left, above Newburgh, Abernethy, with its old Round Tower, was passed. It is beautifully situated at the foot of the Ochils, and is a place of great historical interest, having been at one time a Royal residence, then the see of a bishop and a seat of learning, until these were transferred to St. Andrews. On the right are the villages of Inchyra and Glencarse. On the south bank stands Eleho Castle. A nunnery of the same name also stood a little to the west of the castle. This interesting old castle was the scene of one of Wallace's heroic deeds on his return from France with Thomas de Longueville. On the right, a little further up, is Kinfauns Castle, occupying a fine position on Kinnell Hill, which is the western termination of the Sidlaw range. Its site has been that of a castle for centuries, and is the scene of several incidents described in Scott's works. A short sail round the southernmost portion of Moncrieffe Island brought the visitors to Perth.

Here they were met by Mr. R. D. Pullar, Oehil, and conducted to carriages which were in waiting to convey them to the Commissioners' Hall, where Lord Provost Dewar and the Magistrates took them over the Municipal Buildings, and afterwards entertained them to afternoon tea. The Lord Provost extended a hearty welcome to the visitors, and Mr. E. C. C. Stanford in turn thanked his Lordship, and expressed his delight at visiting the Fair City. Returning to the vehicles, several members of the party drove to the gas works, accompanied by Councillor Wright, who showed the working of Young's oil-gas process, while others had a drive over the length of Bridgend, and afterwards visited the Fair Maid's House, and the East Church with its organ with electro-pneumatic action. Shortly after five o'clock the whole company repaired to the City Hall, and were entertained to a banquet by Messrs. J. Pullar and Sons. The tables were artistically laid out; the front of the gallery was draped with pale blue art muslin, while the platform was covered with a fine collection of plants from Tayside and Rosebank gardens. After the seats running from east to west in the hall had been filled, the following guests, preceded by the Town's officers, took up their position at the top table—Mr. Robert Pullar of Tayside in the chair, and on his right Lord Provost Dewar, Professor Crum Brown, Dr. J. Murray, Lord Dean of Guild Wotherspoon, Dr. Charles Dreyfus, Mr. W. Sharp, Mr. S. K. Muspratt, Mr. A. Coates, of Pitculen, Prof. W. Ivison Macadam, Edinburgh, Mr. J. Stanley Muir, Glasgow; on his left, Mr. E. C. C. Stanford (President), Sheriff Grahame, Mr. R. Irvine, Mr. Wm. MacLachlan, City Clerk, Mr. B. E. R. Newlands, Bailie McNicoll, Mr. J. L. Wade, and Mr. T. Tyrer. Amongst the others present invited to meet the visitors were ex-Lord Provost Whittet, ex-Lord Provost Martin, Bailie Kyd, Councillor Wright, Mr. John Moncrieff, Mr. Robert Keay, city chamberlain, Mr. Thomas Whimster, gas manager. The gentlemen who acted as croupiers were—Mr. R. D. Pullar, Mr. A. E. Pullar, Mr. H. S. Pullar, Rev. A. J. B. Baxter, Mr. John Thomas, sheriff clerk, Mr. W. H. Gregor, and Mr. R. D. Wright, Pullars' Dyeworks. After the dinner the Chairman intimated apologies for absence from Mr. Jas. F. Pullar, of Rosebank Rector Chambers, Mr. John Alexander, Sharp's Institution, Mr. Melville Jameson, procurator-fiscal, Mr. J. D. Lumsden, Huntingtower, Mr. R. W. R. MacKenzie, of Stormontfield and Earlshall, Mr. John Hally, Auchterarder, Mr. R. McKillop, burgh surveyor, Mr. J. Burt-Marshall, Lunarcy, Mr. Jas. Shepherd, Kirkealdy, Bailie Cuthbert, ex-Provost Wilson, Mr. D. M. Watson, of Ballinfield, and Dr. Thomson, Perth Academy. During the progress of the dinner Mr. Edward Nicoll, organist North U.P. Church, played several selections on the grand organ.

The CHAIRMAN gave "The Queen." They could not, he said, say too much in praise of her wonderful reign, and they hoped she would be spared for many years longer to reign over a happy and contented people. They in Scotland were very much favoured by Her Majesty, and he thought they in Perth were particularly favoured, because she passed through the city very frequently on her way to her northern home, and without intruding on her privacy they had an opportunity of seeing her. He would couple the toast with the "Other Members of the Royal Family," and they must not forget the latest addition. If it should come about in the course of things that the little Prince should one day rule over Great Britain, he hoped it would be even greater than it was at present. The National Anthem was then sung.

The CHAIRMAN then proposed "The Ladies." He thought it was an excellent arrangement to have the ladies with them, and he hoped it would be carried out in future. They had ladies with them that day from England, Ireland, Scotland, the United States, and Canada.

Dr. MURRAY, replying on behalf of the ladies, quoted from a French review, with which he agreed, and in which it was stated that in a very short time ladies were to take a large part in scientific research. They could not make research pay so far as money was concerned, but they could make it pay with respect to the higher life, and to a service and duty rendered both to self and country. He thought it was certainly the case that women had a much more acute intellect than men, and knew better how to save the money.

Mr. ROBERT PULLAR in proposing the toast of the "Society of Chemical Industry," said his firm felt very highly honoured indeed that so many gentlemen connected with this industry, both in Great Britain and abroad, had favoured them with their presence there that day. He was sure no more distinguished company had ever been welcomed in Perth—men who were distinguished in many positions as professors, and as lecturers, and as investigators, and as those that were in charge of very large and very important chemical industries. He dated say a good many were rather puzzled as to what chemical industry was. He then quoted from the Journal of the Society, which had now appeared for 13 years, 23 different branches of chemical industry which the members all studied from time to time. It was just by studying such things that the greatness of their country was maintained, and it was by doing these things rightly that they would be able to keep their position. This Society was a very valuable factor in the various chemical manufactures of the country; and he was sure every year it was in existence it would make progress. They had at the head of it at the present moment, a President who knew the subject, and knew it very thoroughly, as was well exemplified by his address on Wednesday at the meeting in Edinburgh. And had there been time one could have enlarged still more upon that; but he could now only say that they, as a firm, welcomed most heartily the members. He had been told that there was one lady member in the Society. He hoped if ever the Society should come again to Scotland, they would pay another visit to Perth, and perhaps have a little more time at their disposal. Referring to the welcome given by the Lord Provost and magistrates, he felt that as a member of the Society they were highly honoured in being so courteously received by the dignitaries of the city. Mr. Pullar concluded by coupling the toast with the name of the President.

Mr. STANFORD said, he ought now to touch on the whole of these 23 subjects mentioned by Mr. Pullar, and probably a good many more. Their President had been already appointed for next year, but he had no doubt that in the following year the lady member spoken of by Mr. Pullar would be elected President. He would be delighted to see that himself, because then they would listen to real eloquence, which some of them were not accustomed to. He thought they were extremely obliged to their Chairman for having discovered the means of bringing their Society so far north. They were, in fact, at the first stopping place in Her Majesty's route to health. He strongly advised them to follow her further north. Mr. Pullar had

discovered that this Society—and this was the attraction—though it might have a very weak head, had a strong appetite. They remembered that Sydney Smith in his libel on the Scottish nation, said it required a surgical instrument to get a joke well into the Scotch understanding. He explained that afterwards by saying that the instrument he meant was a cork's raw. Mr. Pullar had also discovered that that was an instrument too, that was quite able to draw out the English nation. But in the very short time that he had that night he would say nothing more about the Society of Chemical Industry. He wanted to drink the health of their entertainers. They were accepting the hospitality of Messrs. Pullar and Sons, Perth, and with the organ they saw there to almost everything about the city the name of Pullar was associated. Their friend had not only done so much for Perth, but he had done a great deal for the Society of Chemical Industry, and he had never done so much for it as that day. He (Mr. Stanford) only wished they could have seen his works. The Messrs. Pullar employed about 2,000 men and women, and he was told that sometimes no fewer than 15,000 parcels a week were sent out of the establishment. He could not imagine for a moment how that was done. They had not time for Mr. Pullar to explain it, but he did think Mr. Pullar must be, and he knew he was, the greatest authority on parcels in the world. He knew Mr. Pullar was consulted by the Post Office when they began to try—and they failed miserably at first—to deal with the parcels of this kingdom. He believed at one time Perth was a great seat of the glove trade. That had now dropped altogether, he believed. No one had explained it, but it seemed to him perfectly obvious that no one wanted any new gloves now; they all came up to Perth to be cleaned. He knew there were numbers of ladies in London, noble ladies, who had the greatest difficulty with that awful atmosphere—he knew there were cockneys present, and he wanted to give it them—which spoilt their beautiful gowns and made them all black. What was a lady to do if she did not know there was a noble man up in the north who could pull (h)ar out of the difficulty. There was just one other point on which they ought to think of the very beneficent character of this great work, because there was a large class of their fellow-citizens, and especially their countrywomen, that were obliged to keep up a decent appearance with a very small income. He did not think it was possible to estimate the amount of good which was done to this nation in that particular way by the firm of Pullar and Sons, of Perth. Mr. Stanford hoped that, along with his excellent lady, Mr. Pullar would be long spared to enjoy good health.

Mr. PULLAR said he expected when a man had a toast to propose that he would stick to his text. His friend had departed from his text, however, and entered upon a difficult and complicated subject, which certainly they had not time to discuss that evening. If any of the ladies should happen to have a day to spare he would do his best to meet and show them all the interesting features of his works. He felt that it was a very high honour, and he accepted it on behalf of his firm, and they looked not upon themselves alone, as members of it, but also the very able and excellent men who were working along with them. He had now great pleasure in calling upon Professor Crum Brown to propose a toast.

Professor CRUM BROWN said the toast was one which it was impossible to do justice to in the short time he had at his disposal. At all events they must allow him to say three things. First, as to the fair city of Perth. Those who had seen Perth that day for the first time would, he was sure, admit it was a fair city. Although they entered it in a shower of rain, that only increased the beauty of it, for the dull sky set off to admirable advantage the superb environments of hill and wood that surrounded it. The beauty of Perth had been famed from a very early time; for they read when the Romans advanced towards it through a part of the county over which they had yet to march, they broke into exclamations of delight at the first glimpse of it: beauty. So much for the city; he had no time to dilate further upon it. Then

he came to the trade of Perth. They all hoped the trade of Perth would always flourish. He had next to speak of the government of Perth, coupled with the toast the name of Lord Provost Dewar. That such a city might remain fair and beautiful and healthy and prosperous depended to a very considerable extent upon those who governed it. And when they found it prosperous and beautiful, they might be sure it was a well-governed and well-managed city; and he believed that that was the case here. Lord Provost Dewar was one of the most enterprising and most zealous chief magistrates in the country. He was, he believed, the youngest chief magistrate in this country—the youngest man that ever occupied the position of Lord Provost. It was a great advantage that an old city should have a young Lord Provost. The rejuvenescence of the world was one of the great points. They had a good specimen of a gentleman beginning young, and he hoped Lord Provost Dewar had a long and prosperous reign before him. He had extreme pleasure in submitting for their acceptance the toast of "The City and Trade of Perth and the Lord Provost of Perth."

Lord Provost DEWAR returned thank for the very hearty reception they had given the toast. They were all very much pleased and honoured that the Society had paid a visit to Perth, and they welcomed them very heartily on account of the distinguished position that Society occupied, on account of the personal character of all the members, and also on account of their being the guests of their respected citizen, Mr. Pullar. In regard to the city of Perth, he did not think too much could be said of it. It had that peace and quiet and contentment about it, which, as a business man, he did not very much like. He had not the same difficulty in speaking to this part of the toast as he had about the trade of Perth. He was sometimes embarrassed in speaking of the city trade in presence of representatives from other communities that had advanced by leaps and bounds—which they in Perth undoubtedly had not done. He had sometimes to apologise in replying to this toast for the disappearance of the glove-making industry; and he was obliged to their President for suggesting a reason which had not occurred to him before. He was sorry to hear from Dr. Murray that his end of chemical science did not pay; but he could assure them the other end paid very well; and the industry of Perth in that respect was as flourishing as it possibly could be. They were all very much interested in local government; they did what they could to live up to the situation Providence had placed them in—he meant the situation of the town. All did their best to keep it as it was long ago, still the Fair City.

The CHAIRMAN said they had an excellent man at the head of the School Board, and he had very great pleasure in proposing the health of the Rev. Mr. Fleming, chairman of the School Board.

Rev. Mr. FLEMING thanked Mr. Pullar very much for the kind way in which he had proposed the toast of the School Board of Perth, coupled with his name. He might say in the presence of so influential and important a Society as that which they had the honour of seeing there, that they felt the claim which technical science had upon them; and it was their determination to keep up not only all the existing agencies, but, if possible, to extend and render them still more efficient. He had also to state that it was the desire of the present school board to do all that they could in the interests of the science of chemistry. They felt that this science had a very great future before it, and after what he had learned that day, he felt that the researches of the eminent men in connection with this science in future were destined not only to revolutionise the chemical industries of the country, but also the usual associations of the dinner table. He was sure that they all took an interest in everything connected with this science. The school board took an interest in it because they felt that chemistry played a most important part in the industries of this city, more especially of that industry of which their Chairman was the distinguished head. They felt it was their duty to take an interest in it from the circumstance that Perth was a large agricultural centre, and chemistry, he thought, was

very much bound up with the progress of agriculture. He had pleasure in stating the school board had given great importance to the study of chemistry in their educational institutions. They had attached great importance to it in their curriculum in the Academy, which, he might state, was now, as it had been for centuries, the leading educational institution in the city and county. He might also state that great importance was attached to that branch of study in Sharp's Institution, with which his friend, Mr. Pullar, was very intimately associated. They had at the head of the mathematical department of the Academy, Dr. Thomson, a gentleman who was quite an expert in everything connected with chemistry, and he had sent from his school some most distinguished students, and he had no doubt they would soon be in the classes which were so ably presided over by Professor Crum Brown. In conclusion, Mr. Fleming said the visit of the Society to Perth would give an impetus to the study of all the pursuits connected with chemistry.

The CHAIRMAN announced that they had reached the end of the programme, and gave "Sorry to part," &c. "Auld Lang Syne" having been sung, accompanied on the grand organ by Mr. Nicoll, the large party left the hall, and were driven to the station, where a special train was in waiting at 7.30 to take them direct to Edinburgh.

#### THE SMOKING CONCERT.

In the Reception Room of the Waterloo Hotel some 60 or 70 members of the Society attended an enjoyable Smoking Concert, which, commencing at 9.30 p.m., was continued into the small hours of the following morning. An attractive programme of vocal and instrumental music, &c. had been provided, and was duly honoured in the performance; but there were super-added some songs, recitations, and humorous speeches by other members of the company, in which, amongst others, Professor Crum Brown, Mr. B. E. R. Newlands, and the ex-President took part. It will be some time before those who heard it will forget the humorous version of the "Babes in the Wood," so minutely given by Mr. E. C. C. Stanford.

#### THE POWDERHALL REFUSE DESTRUCTOR, EDINBURGH.

Several members took advantage of the opportunity afforded to see the City Destructor, and were shown over the works by Mr. Mackay, the Inspector of Cleaning and Lighting for the City, on Saturday morning, July 21st.

### DISCUSSION ON THE PAPER OF MESSRS. SCHWEITZER AND LUNGWITZ ON THE COMMERCIAL ANALYSIS OF LARD.

(This Journal, 1894, 614—616.)

Mr. RIMMINGTON (Borough Analyst, Bradford) said that he found the results of authors' experiments so various and different, that he had come to hear what other people had to say on the subject. Referring to Mr. Stock's experiments, he had taken a sample of what he thoroughly believed to be pure lard as he obtained it from his brother. The melting point was 98° F.; the iodine absorption was 49; and the amount of ether-washed deposit from 3 cc. was 118 mgrms. The same with 5 per cent. of beef-suet showed that the amount of crystallisation was 187. In lard of his own rendering, the melting point was 96° F.; iodine absorption 52; and the amount of crystals 80. In a commercial lard the melting point was 87° F.; the iodine absorption was 60½; and the ether-washed deposit only 27 mgrms. He had not made any attempt at such elaborate analyses as the authors of the paper evidently had done.

Mr. A. H. ALLEN said he congratulated the Section upon having before it a paper by two American members of the Society. It showed that the Society was not simply of a local or even of a national character, but that its ramifications extended all over the world. The authors of the paper appeared to have dealt with the subject very completely, and he did not doubt that their results would be of permanent value. According to the book-writers, animal fats all had a closely analogous chemical composition, varying only in the relative proportions of olein, palmitin, and stearin they contained. But if this were true, it was difficult to account for the very different appearance presented under the microscope by pure lard, beef-fat, and other lard substitutes. He observed that the authors practically adhered to the Manfield method of preparing the lard crystals for microscopic examination; in his own experience that plan still held its own. The use of cotton-seed oil for mounting the crystals was no doubt original on their part, but it had already been used in England. The authors laid great stress on the crystallising point of the lard, as an indication of purity, which, in England, analysts would scarcely be inclined to do. When the sample was proved pure by other means, the crystallising point might afford a useful indication of its origin, but in practice, analysts had to report on lards of which they knew nothing, and the crystallising point varied very greatly according as the article was real leaf-lard (prepared from abdominal fat), back lard, or the hog-fat prepared so largely in Chicago and other American cities, by rendering the fat of the whole animal. This product was of a very different character from the old-fashioned lard of English manufacture, and he thought this should be borne in mind in interpreting the authors' results, which were probably applicable solely to the American product. The method used by the authors in determining the crystallising point differed from Dalican's test for the solidifying point of fatty acids, in the fact that he directed the substance to be stirred while cooling, whereas the authors avoided agitation. The subsequent rise of temperature observed when oleo-stearin was under examination, and the absence of the phenomenon in the case of cotton-seed oil, was of interest and might become of practical value.

With regard to the rise of temperature on treatment with sulphuric acid, there was no doubt that the strength of the acid employed was of the first importance. That is to say, that the temperature developed was largely affected by the exact strength of the acid used. But he had grave doubts of the practical advantage of making up an acid containing 100 per cent. of H<sub>2</sub>SO<sub>4</sub> by mixing fuming sulphuric acid with "acid of 66° Beaumé." He believed that equally good results were obtainable with acid of 98° per cent., which

was an article obtainable in commerce; but in any case the strength employed must be rigidly adhered to throughout a series of comparative experiments, or the figures obtained were not worth the trouble of recording. But he objected to the authors describing ordinary strong sulphuric acid as "acid of 66° Beaumé." It had been shown repeatedly that the density was valueless as an indication of even the approximate strength of concentrated sulphuric acid, but when the density was expressed in degrees Beaumé, and not in actual specific gravity, there was no certainty to 10 per cent. as to the actual strength of the acid used. It was a matter of astonishment that American chemists, who were ahead of those in the old country in so many respects, should continue to use the clumsy hydrometer of Beaumé, instead of expressing their densities in actual specific gravities, or in terms having some less arbitrary relation thereto than was borne by the degrees of Beaumé's scale. It was bad enough if one had to deal with accurately graduated instruments, but it was notorious that the Beaumé instruments made by different manufacturers differed very materially in their indications, and there was not one in ten of the makers who could tell on what principle he graduated them, except that they were tested against some instrument kept as a standard, and usually of unknown history. One was prepared to find the French continuing to record their results in degrees Beaumé, but that American chemists should do so was extraordinary.

As to the iodine absorption, he observed that certain experiments showed a variation from 57 to 85. Assuming that there was no clerical error here, he should regard these limits as extremely doubtful, and should require to know the precise conditions of operating before he accepted them as accurate. He congratulated the authors of the paper on their attempt to shorten the time of treatment in Hübl's process, but looked somewhat shyly at any method the accuracy of which depended on a precise adherence to a particular time and temperature. We had too many of such arbitrary processes already, and he should prefer to allow a longer time if by so doing he could ensure the completion of the reaction. It was only in this manner one could hope to avoid the errors due to personal equation, and could render the results obtainable in different laboratories fairly comparable.

With respect to the tests for cotton-seed oil based on its reducing action on silver nitrate, gold chloride, or phosphomolybdic acid, it was a remarkable fact that this reducing action was not more generally exercised by vegetable oils, supposed to be of a very similar composition to cotton-seed oil. Yet in one of the earlier forms of the silver-test the reagent was actually made up with rape oil. There were so many substances which exerted a reducing action on metallic solutions that he should think a long while before he based a positive opinion as to the presence of cotton-seed oil on the results of such a test. In short, the reduction tests should be regarded rather as useful indications than as absolute proof, and ought in every case to be supplemented by other methods of examination.

Prof. F. CLOWES said that analysts who had used the Mauméné process, considered it not wholly reliable; that although this test was useful when applied to many oils that did not occur as adulterants in lard, it had not been found correct when applied to oils or fats used in the adulteration of lards. The least differences as to detail in the method of working would be sufficient to cause a very great difference which was not in any way due to the fats or oils. Whether the analysts had paid attention to every detail in conducting the test, he could not of course say; but, presumably, they worked with ordinary care, and it was the test that was at fault. If a test could play such pranks as these, they must not place their reliance too firmly upon it. That was the extent of his information. He regretted it was not founded upon personal experience.

Dr. TRUMAN said that the great difficulty was to obtain quantitative determinations of adulteration of lard with cotton-seed oil, &c. The specific gravity, if normal, was no proof of purity, as mixtures might be made giving normal specific gravity. The iodine number was open to the

same objection. But if the normal number was exceeded, then one could estimate amounts in two ways. Taking the iodine number, e.g., 90, then the percentage of cotton-seed oil in the sample would be shown by the formula  $100 \left( \frac{90 - 60}{105 - 60} \right)$  (lard taken at 60 and cotton-seed oil at 105). Taking specific gravity of lard and cotton seed oil at 100° F., as 0.906 and 0.9135 respectively, then the percentage of cotton-seed oil was found by the equation,  $100 \left( \frac{\text{specific gravity found} - 0.906}{0.9135 - 0.906} \right)$ .

The qualitative tests were plain and abundant enough. Personally he preferred the  $\text{AgNO}_3$  reduction test to the phosphomolybdic acid one; it was more certain. The sulphur chloride test was useless. Colour reactions with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ , rise of temperature with  $\text{H}_2\text{SO}_4$ , solidification point and microscopical examination, all of them he found most useful.

He agreed as to the value of the six tests mentioned on page 615, but with the exception of the first, he had made use of them for years, and other analysts might have used the phosphomolybdic test. The authors state that less than 10 per cent. may escape detection by this test. The heating of the solution for the iodine number determination was an improvement, as it saved so much time.

Allen (Com. Org. Analysis) II., 56) describes the rise of temperature test fully. It was a pity that no figures are given by the authors of the paper; and that Allen gives no figures for lard.

Messrs. H. SCHWEITZER and E. LUNGWITZ (New York) send the following reply:—

A few points in our article evidently need further explanation. We repeat that we do not consider any one of the six tests, neither the crystallising point nor the test with nitrate of silver, as characteristic enough to determine the purity of lard. Our contention is that all of them must be made and that the final conclusion must be drawn from the results of all. After an exhaustive examination of all the tests hitherto known in literature, these six tests were selected, because they give, in our opinion, the quickest and most reliable final result.

It is true, and we find it daily confirmed that the crystallising point is of the greatest importance as an indication of the purity of lard. However, we state with regret that the presence of cotton-seed oil does not in all cases prevent the rise of temperature. According to our experience the temperature does not rise when compounded lards, prepared by mixing about 75 parts of cotton-seed oil with 25 parts of oleostearin, are examined, or when such mixtures are added in large quantities to genuine hog fat. If, however, only very small amounts of cotton-seed oil have been added to pure lard in conjunction with little oleostearin, then the temperature will rise. But the observations made while carrying out the test will furnish valuable material to the analyst. The temperature will sink very slowly, and will probably not go below 29° C., while the subsequent rise will most likely exceed 1° C. All these differences are best found out by comparative examination of lard of known origin with mixtures of known composition. To facilitate such comparative tests we have prepared about 100 mixtures showing the consistency of commercial lard but compounded in varying proportions from lard, lard-oil, cotton-seed oil, and oleostearin. By referring to these standard samples we possess a valuable guide whenever we meet difficulties in our analytical examinations.

With regard to the variation of the iodine number observed by different authors, we quote from Wiley's publication: "For instance, a sample of intestinal lard absorbed 57.34 per cent. of iodine, the leaf-lard from the same animal absorbed 52.55 per cent., the foot-lard 77.28 per cent., the head-lard 85.03 per cent."

We add that Wiley determined the iodine number after the old Hübl method. Quite recently† Samuelson pronounced the iodine number to be the only known reliable

\* Bulletin, 13, 417, 118.

† Z. its. f. anal. Chem., 33, 1-2; and this number, p. 766.

test for the purity of lard. We are obliged to differ very much from him. Since we examine weekly a sample of compounded lard containing 70 per cent. of genuine hog-fat and 30 per cent. of a mixture of cotton-seed oil and oleostearin which shows the correct iodine number of 60–61 after the Hubl method. The same lard also gives the Maumené figure for pure lard, whereas the results of the other four tests distinctly show adulteration. As to the reduction-test with nitrate of silver, we are of the opinion that reliable results can only be obtained if the directions of E. Millian are strictly adhered to. We attribute great importance to this test, and we prefer it decidedly to the reaction with phospho molybdic acid.

Finally, we say, with respect to Maumené's test, that we direct the use of an acid of 100 per cent.  $\text{H}_2\text{SO}_4$  because we find that the rate of action between fat and sulphuric acid increases with the strength of the latter. We do not doubt that acid of 98 per cent.  $\text{H}_2\text{SO}_4$  would also give good comparative results. But what we want to point out most distinctly is that the acid must be always of the same strength, and must be constantly controlled by analysis.

By using the term "66 Bé" we meant any commercial acid which by the addition of fuming acid should be transformed into acid of 100 per cent.

We did not give any analytical results for the Maumené test, as, owing to the personal character of the results, it is obviously impossible to lay down precise figures. Every analyst ought to find his own constants for his apparatus.

The following figures were found:—

---	Initial Tempera- ture of Fat.	Tempera- ture of Acid.	Final Tempera- ture.	Rise.
	° C.	° C.	° C.	° C.
Lard.....	35	35	70.0	35.0
" oil.....	35	35	80.3	45.3
Oleostearin.....	45	45	76.9	31.9
Tallow.....	45	45	76.6	31.6
Cotton-seed oil.....	35	35	90.5	61.5
Armour's compounded lard.	35	35	93.0	58.0

Generally we found 33.5–36° C. as rise of temperature for pure lard, and 61.5–63° C. for pure cotton seed oil; whereas Wiley found as extreme rise 38.8–42.1 for pure lard, and 80.4–90.2 for cotton-seed oil.

We cite the following absurd figures found for the above lard under the above conditions with an acid sold in New York as "chemically pure compound, 66 Bé," which on analysis was found to contain 92 per cent.  $\text{H}_2\text{SO}_4$ .

---	Initial Tempera- ture of Fat.	Tempera- ture of Acid.	Final Tempera- ture.	Rise.
	° C.	° C.	° C.	° C.
Lard.....	35	35	55.8	18.8
" .....	35	35	71.1	36.1

## Communication.

### CENTRIFUGAL METHODS OF MILK ANALYSIS.

BY ANDREW SCOTT.

WITHIN the last few years an entirely new principle has been applied to chemical analysis—that of centrifugal force; and it was with the object of ascertaining how far centrifugal methods could be relied on for milk analysis, that the experiments of this paper were undertaken.

The principal machines in use are the Löffmann Beam and the Lister Babcock Testers. In the former we have a metal arm fitted on a spindle, and to each end are riveted brass cups to hold the test-bottles. At the lower extremity of the spindle we have a toothed pin working in a larger wheel which acts as the driving wheel—each revolution of the latter being equivalent to eleven of the horizontal arm. According to the directions, 15 cc. of the milk to be tested are put into the bottle, 3 cc. of a mixture consisting of equal parts of fusel oil and strong hydrochloric acid are added mixed, and the strong sulphuric acid (9 cc.) poured in slowly, with agitation, until the bottle is filled nearly to the neck.

The liquid becomes hot, and the casein is completely dissolved, a dark reddish-brown solution being formed. The neck is filled to near the zero point with a hot mixture of sulphuric acid and water, and the bottles whirled in the centrifugal machine for from one to two minutes. Milk very poor in fat may require from three to four minutes. The volume of fat which rises in the neck can be read off directly.

The results by this machine are slightly on the high side, and much has been written on the subject of the fatty layer, which is slightly darker than that obtained by the Lister Babcock machine, to which I shall next refer.

I made a blank experiment with the bottles, using the usual proportions of acid and fusel oil, but with water instead of milk. After whirling for the usual time, I found a dark layer had separated and risen to the surface, representing 0.10 to 0.15 in the graduation. Then a sample of milk-fat drawn from one of the bottles and tested with silver nitrate solution gave a decided precipitate of silver chloride, so that the layer probably contains both hydrochloric acid and amyl alcohol, or some compound produced by amyl alcohol.

Various experimenters make the difference in fat between this process and Adams' coil 0.004 to 0.2 per cent. I have done a number of tests, and find that between duplicates the greatest difference is 0.15 per cent., while the greatest discrepancy between it and Adams' coil method is 0.13.

The following representative tests, taken from my notebook, show the results alongside those obtained by Adams' process. (A number of the samples were also tested by Dr. Bell's process, which gave results slightly lower than those obtained by Adams' method.)

Löffmann Beam.	Adams.
3.30	3.32
2.15	2.02
2.42	2.47
3.27	3.23
2.00	2.10
1.30	1.41
2.50	2.47
1.30	1.35

The next machine to which I have referred is what is known as the Lister Babcock. This method was introduced

by Dr. Babcock, of the United States, while the latest modification is produced by Messrs. R. Lister and Co., Limited, of Dursley. In this we have a driving wheel as before, inside which works a toothed pin; by means of a pair of bevel wheels below, the direction of motion is changed and rotates the cast iron flange, the centre of gravity being thus brought lower down than in the other machine. In the iron flange we have slots cut at intervals, in which rest the steel cages holding the bottles. These latter are graduated in a similar fashion to those of the other machine.

17.6 cc. of the milk to be tested is pipetted into the bottle held in an inclined position, then 17.5 cc. of sulphuric acid (sp. gr. 1.831 to 1.834, determined by the hydrometer supplied with the instrument). The milk and acid are well mixed and the bottles whirled in the machine for 10 minutes. After this time they are filled to the centre of the stem with boiling water, and the tank which surrounds the whole, filled to the bottom of the test-bottles. The machine is rotated for two minutes and the fat measured. The speed during the test is 650 revolutions per minute; that is, 65 turns of the driving wheel.

The fat-results are low by this machine, but by a constant figure, and it is necessary to add 0.3 to the measured fat to obtain the correct percentage. I have had occasion to carry out a large number of tests with this machine, and have never got a greater difference than 0.1 between duplicates, while the variation above or below Adams' coil is only 0.11 in the greatest.

The following tests, taken from my note-book, include the greatest and least differences:—

Lister Babcock.	Adams.	Error.	Lister Babcock.	Adams.	Error.
3.40	3.42	- .02	2.40	2.33	+ .07
3.80	3.77	+ .03	2.10	2.10	..
3.20	3.23	- .03	2.10	2.02	+ .08
3.30	3.32	- .02	2.00	2.00	..
3.20	3.34	- .04	1.55	1.59	- .04
2.80	2.91	- .11	1.45	1.52	- .07
2.70	2.78	- .08	1.40	1.38	+ .02
2.50	2.57	- .07	1.35	1.41	- .06
2.50	2.58	- .08	1.39	1.35	- .05
2.50	2.47	+ .03			

(In every case 0.3 has been added to the actual reading of the Babcock machine.)

The low readings in this machine are said by some to be due entirely to the graduation of the bottles; by others, to a proportion of fat remaining in the acid liquid and consequently being lost to measurement. Probably both are responsible, but certainly small globules of fat may often be observed in the acid liquid; and on submitting a sample of milk to centrifugal force for 15 minutes, or five minutes longer than the directions advise, a further quantity of fat rose to the surface representing 0.1 and 0.15 per cent. of the total fat in the sample; again, on working the machine for the usual time, but at double the speed, I succeeded in obtaining 0.15 more fat in the milk. This latter course, however, I would not recommend, as the bottles are apt to break when driven at such a high speed. I find that as a rule 0.3 added to the reading gives the correct percentage of fat; in some cases of milks between 1 and 2 per cent. fat, 0.35 seems a better figure, but on studying the table it is evident that 0.4 is too high.

The advantages of centrifugal analysis for milk are obvious—(1) reliability, I have shown; (2) accuracy of results is also clear; (3) the saving of time is patent. All we have to do is to take the specific gravity of the sample by means of the bottle or a reliable hydrometer, to whirl the measured quantity in the machine, and by Fleischman's or Richmond's formula we get at a glance the total solids.

The ash should also be done. (4) Seeing, however, I would not advocate the use of the centrifugal machine for prosecution or suspected samples, we have this further advantage—that fresh determinations by Adams' or Bell's method can be proceeded with while the milk is sweet.

On the whole the Lister Babcock machine is to be preferred. It is a little cheaper; I have found it give quite as trustworthy results, while it is much simpler. The whole apparatus consists of the machine and bottles, a milk pipette, a measure for the acid, and a hydrometer to test the same. Let me notice here that it is necessary to use the acid of the fixed strength recommended, as stronger acid not only darkens the fat, but causes bad separations, particles of charred curd rising to the surface, and making the reading very difficult.

Nothing but sulphuric acid being used in this machine, the fatty layer consists of nothing but butter-fat; in the Leffmann Beam, on the other hand, we have the use of a volatile acid, hydrochloric, and also amyl alcohol, which is by no means pleasant to work with, while we cannot be sure that pure fat only separates and rises in the stem.

Though it is necessary to test the acid for the Lister Babcock machine, Richmond has shown that it is not only necessary to test the acid for the Leffmann Beam, but variations in samples of amyl alcohol render it necessary to test each lot of this too.

It has sometimes been found difficult to read the fat layer in the Leffmann Beam tester, especially in cold weather, owing to congelation, but that is obviated in the Babcock machine by the hot-water tank, though I have not found the hollow lid filled with hot water, as adopted in a later form of machine, necessary.

The centre of gravity in the Leffmann Beam being so high, causes great oscillation, which is especially objectionable in a chemical laboratory, besides which we have at least a possible danger of one of the cups flying off when driven at such a great speed. One chemist indeed thinks it safer to erect an iron screen round his machine.

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*Action of Aluminium on Cast Iron.* Bull. Soc. Chim.  
11—12, 1894, 374—379.

See under X., page 737.

*Execution of Masonry and Brickwork during Frost.*  
Alfred Greil. Zeits. des österr. Ing. und Arch. Ver. 1894,  
95. Proc. Inst. Civil Eng. 116, 1894, 9—11.

THE information embodied in this paper is the result of the investigations undertaken by a committee of the Austrian Union of Engineers and Architects to determine the most reliable method of proceeding with masonry or brick construction during severe frost.

The first portion of the report summarises the previous records and experiments on the subject, and the experience of experts in Russia, Sweden, Norway, and elsewhere. The consensus of opinion is in favour of Portland cement, with a certain quantity of common salt in the water, and the brick or stone used dry.

The general results indicate that lime-mortar is useless for either brick or stone. Roman cement gives fair results for brickwork, and Portland cement good results; both are improved by mixing with warm water, and distinctly improved by the addition of salt. The "frostproof" Roman and Portland cement give excellent results. For masonry, Roman cement is not very satisfactory, though improved with salt; Portland cement gives good results, though not improved by warm water, but very good with the addition of salt.

It appears in brief that reliable results are to be looked for only with Portland cement used with cold water and the addition of 7 per cent. of the cement and water in common salt; this applies both to brickwork and to masonry.

### PATENTS.

*Improvements in Apparatus for Condensing Vapours and Heating or Vaporising Liquids respectively.* W. Henneberg, Hamburg. Eng. Pat. 5262, March 13, 1893.

THE apparatus consists of a number of pipes or channels, through which the liquid or vapour is passed, and surrounded by a vessel containing a liquid such as water, which latter is caused to circulate through the vessel and so heat or cool by conduction the liquid or vapour contained in the pipes. To promote the efficiency of the apparatus, ribs and pockets are formed in the side walls of the channels to agitate the contents and thereby bring new particles under the action of the heating or cooling medium.—E. G. C.

*Improved Still and Apparatus for the Distillation of Ammoniacal Liquid and other Fluids.* G. Pettigrew, Middlesbrough. Eng. Pat. 10,171, May 23, 1893.

See under VII., page 734.

*Improvements in Apparatus for Evaporating Liquids by means of Steam.* E. Latham and E. G. Guyot, both of London. Eng. Pat. 10,467, May 27, 1893.

A NUMBER of pairs of concentric steam tubes are arranged in the evaporating vessel, the inner tubes being open at both ends and completely surrounded by the outer tubes, which are closed at the top and open to a steam exit chamber below. Steam is allowed to circulate through the inner tubes and in the annular space between the inner and outer tubes, thereby heating the water contained in the evaporator. The evaporated vapour is collected by a

perforated ring-pipe and led away to a condensing arrangement, while the sediment left in the vessel is discharged by a suitable cock.—E. G. C.

*Improvements in Thermostatic Instruments.* A. G. Brookes, From G. W. Gregory, Boston, U.S.A. Eng. Pat. 11,052, June 6, 1893.

THE apparatus is intended for use in an electric circuit so as to give an alarm when the temperature becomes excessive, as in the case of fires and the like. It consists of a capsule containing a volatile liquid fastened down to a stout non-conducting base, and connected to the electric terminals of a circuit containing an alarm bell by means of strips of fusible metal passing through the solid base. When the temperature rises, the expansion of the liquid within the capsule forces the latter away from the base, and in so doing ruptures the fusible connections, thereby breaking circuit and giving the alarm. Should the capsule fail to rupture the connections, a slight increase of temperature will melt the solder and break circuit.—E. G. C.

*An Improved Machine for Straining Pulp and the like.* P. Reinicke, Coblen, Germany. Eng. Pat. 11,531, June 12, 1893.

THIS is an improved machine for straining pulp and the like, having fixed on a rotary shaft a number of discs adapted to reciprocate within splices, on both sides of which annular screens are arranged, the said shaft being caused to produce abrupt reciprocating motion in an axial direction for the purpose defined. The discs are inclined upon the shaft of the strainer, or are corrugated, so as to give one or more lateral impulses when revolved.

*A New or Improved Hydrostatic Apparatus for Automatically Mixing with Water, or other Liquid, Disinfectants, Softening or Purifying Substances, or Saturated Solutions of any Soluble Substances in Definite Proportions.* F. Spence, Newcastle. Eng. Pat. 13,146, July 5, 1893.

THE apparatus consists of a conical vessel of glass or earthenware, provided with an external channel, terminating outside the vessel near the top and communicating with the interior of the vessel below; the top of the vessel stands above the level of the water in the tank or cistern in which it is placed. While the tank is being emptied, water flows out of the vessel through the disinfectant or other substance contained therein and mixes with the water outside, while during the filling of the tank, water flows into the vessel and forms a solution of the substance ready for discharge at the next emptying of the tank.—E. G. C.

*Improved Apparatus for Cooling or Warming Liquids.* R. Ch. Baker, London. Eng. Pat. 14,145, July 21, 1893.

THIS invention relates to the shape of tubes used in open-air coolers, consisting of a number of horizontal tubes disposed in rows one above the other, over which the liquid to be cooled runs down in a thin stream, whilst the cooling liquid circulates through the tubes in an opposite direction. The new tubes are of elliptical section with the major axis horizontal, the surface of the tubes being corrugated longitudinally, and each tube carries along its underside a longitudinal depending fin or blade serrated or undulated at the lower edge.—B.

*Improvements in Bottles for Holding or Containing Poisons or Poisonous Liquids.* R. H. Quinn, Pendleton, Lancashire. Eng. Pat. 11,553, July 28, 1893.

THE bottle is constructed with a flat side upon which it can rest, and the two adjacent sides and end are bevelled so as to make the top side short and narrow. The neck is placed obliquely at the end and above the level of the top, so that

when the bottle is laid upon its flat side the contents cannot run out if it be uncorked. The word "poison" is moulded upon the upper side, and the end is so narrow that the bottle cannot stand upright. The sides of the bottle are made so narrow that to grip it properly the fingers must come into contact with the surface on which it rests.

—E. G. C.

*An Improvement in Apparatus for Drying Animal and other Matters.* W. C. Carne, Birkdale, and W. E. Rowlands, Liverpool. Eng. Pat. 16,198, August 28, 1893.

THE object of this invention is to economise first cost in apparatus, also time and fuel used in the operation. The drying cylinder (in which an agitator revolves) is enclosed in a steam boiler, either entirely, or except at the ends. By this arrangement there is little loss of heat by radiation, and no necessity for the discharge of condensed water, which is required when the ordinary steam-jacketed cylinder is employed.—J. J. K.

*Improvements in Drying Apparatus or Chambers relating to the Drying and Preserving of Animal, Vegetable, and other Substances.* T. Christy, London. Communicated by K. F. Töller, Bremen, Germany. Eng. Pat. 21,787, November 15, 1893.

THIS invention relates to an apparatus for drying (without the application of heat) organic or inorganic substances, which are liable to decompose when dried by heat, or exposed to the action of open air. The apparatus is composed of a chamber of zinc, or wood lined with zinc, the door of which is made air-tight by means of india-rubber or other fittings. The material to be dried is placed in boxes or trays, which are supported on brackets in the chamber. The water-absorbing chemicals, such as sulphuric acid, chloride of lime, or unslaked lime, are placed in a receptacle on the bottom of the chamber, and the door is then hermetically closed, when the drying process commences. The same substances are proposed for the purpose of preventing shop windows from becoming wet in cold weather, and for preserving surgical instruments and other metallic goods free from humidity.—J. J. K.

*An Improved Fluid for Preventing and Removing Incrustation in Boilers.* S. Borecký and J. Komčstik, Pardubice, Bohemia. Eng. Pat. 5431, March 15, 1894.

CAINED soda, oil, oil soot, lime water, and granulated zinc, are mixed together in the following approximate proportions:—Calcined soda, 60 parts; olive oil, 2 parts; oil soot, 1 part; lime water, 80 parts; granulated zinc, 1 part. One part of this fluid is added to every 200 parts of water in the boiler.—J. J. K.

*Improvements in Filter Presses.* T. F. Seitz, Kreuznach, Germany. Eng. Pat. 5973, March 22, 1894.

THE principal improvement embodied in this invention consists in the application of means for shutting off the liquid from a number of the press-plates, thereby reducing the number of plates in operation at any time as may be desired. The accompanying figures indicate the arrangement.

The filtering liquid enters by the lower pipe *o'*, and, having passed through the filtering surfaces into the hollow press-plates, is emitted through the pipes *r* into the upper collecting pipe *o*, whence the purified liquid is withdrawn. If it be desired to exclude any of the press-plates from the operation, the plugs *T* held on the end of tubes *1* are pushed forward as shown, confining the liquid to the space in front of the plugs. A metal plate *e* is further inserted behind the last press-plate in use, shutting off the liquid from the space behind. The enlarged section shows the construction of the plugs *T*, the india-rubber ring *3* being held between

the flanged caps 2 and 5 secured to the tube *1*, and to the concentric rod 4. On the rods 4 being turned after the

plugs have been pushed into the desired position, the caps 5 are screwed against the india-rubber rings, which by their expansion make tight joints within the pipes *o* and *o'*.—B.

*Improvements in and relating to Apparatus for Distilling Sea-Water and other Liquids.* H. E. Fouché, Paris. Eng. Pat. 6594, April 2, 1894.

THE improvements consist in the application of "triple effect" to the distillation of sea-water, in combination with the use of low-pressure steam for heating. The apparatus is of the tubular kind, provided with parallel tubes for the purpose of evaporation and with coils for condensation. The steam for heating the last set of tubes is taken from the third cylinder of a triple-expansion steam engine, or reduced to equally low pressure by means of a reducing valve if taken from an auxiliary boiler when the main engines are not working. The sea-water is heated to nearly boiling point before entering the apparatus, by being passed through a feed heater, and is kept in constant circulation in each department by means of special pumps. The steam given off in the final vessel is used for evaporation in the second vessel, and the vapour raised in the latter serves for heating the third. The condensed vapours are collected and returned to the fresh-water cistern, and the pressures in the various sections are maintained and equalised by means of water columns and siphons between adjacent vessels, the whole of the arrangements working automatically after the first start.—B.

*An Improved Filter for Air, Gas, Steam, and the like.* K. Moeller, Brackwede, Germany. Eng. Pat. 7523, April 16, 1894.

THE filter consists of a casing traversed by vertical tubes of filtering material opening at both ends into chambers attached to the casing. The dust-laden air enters the tubes at both ends, leaving the dust inside the tubes, whilst the purified air passes into the casing which is provided with outlet branches. Movable brushes are fitted, one in each tube, and, on being passed up and down, deposit the dust in the lower chamber, where it can be collected and removed in any convenient manner.—B.

*Improvements in or appertaining to the Pipes or Tubes of Heating, Cooling, or Evaporating Apparatus.* W. P. Thompson, Liverpool. From A. Dumas, Brévaux, France. Eng. Pat. 3182, April 25, 1894.

This invention contemplates insertion into tubes for heating or cooling apparatus of longitudinal partitions or wings of various shapes in cross section, the purpose being to increase the metallic surfaces of the tubes. The partitions are removable, and may be either straight or of helical form longitudinally.—B.

## II.—FUEL, GAS, AND LIGHT.

*Water-Gas in America.* F. Bredel. Zeits. angew. Chem. 1891, [10], 292—293.

COMMENTING on the observations of Lunge (Zeits. angew. Chem. 1894, 137) that the supply of gas-coal is failing in the United States to such an extent that ere long (perhaps even now) it will be necessary to import gas-coal from England, the author remarks that on the contrary, the United States is the richest of any country both as regards the quantity and quality of gas-coal. The following are the more important coal-fields:—Pennsylvania, whence the best gas-coal is obtained, viz., the so-called Youghiogheny coal. West Virginia; the gas-coal here is richer in sulphur than the last-named. The coal of the Indian Territory is a relatively good gas-coal and is much used in Texas. The Colorado coal-field yields a very good gas-coal. The coal of the State of Washington is also considerable in quantity, and good in quality as a gas-coal.

With the best Youghiogheny gas-coal a yield\* of 5—5.15 cub. ft. of gas per pound of coal is afforded. The lighting power of this gas is 18—20 candle-power (London Parliamentary). The author then enters into details respecting the gas and coke production of the various sorts of American coal.

Coal-gas is cheaper than water-gas when both are calculated to candle-power; the only advantage that water-gas possesses over coal-gas is that the former possesses an illuminating power of 23—28 candles per 5 cub. ft., whereas the highest limit that can be obtained with the latter, is 20 candle-power. Many manufacturers enrich their coal-gas with naphtha gas, which is made in the same way as Pintsch's gas.

In many States a mixture of two-thirds coal-gas and one-third water-gas is supplied; this gives a very beautiful light equal to 22 candle-power. The following table shows the price and quality of the gas supplied in various parts of the United States:—

	Price per 1,000 Cub. Ft.	Illuminating Power in English Candles.	
New York .....	Dols. 1.25	22	Mixed gas.
Philadelphia ....	1.60	22	"
Cleveland .....	0.80	18.75	Coal gas.
Wheeling, W. Va.	0.75	18	"
Chicago .....	{ For lighting gas 1.20 For heating and motive power 1.00 }	23	Water-gas.
Milwaukee .....			
Baltimore .....	{ For lighting gas 1.00 For heating and motive power 0.80 }	24	Water-gas (1) (Coal-gas (1/2)).
St. Louis .....			
Baltimore .....	1.25	28	Water-gas.
St. Louis .....	1.18	20	Mixed gas.

Contrary to Lunge's statement, purification of gas with ferrous oxide is more general than purification with lime. The latter is used in very few factories, and then only for the purpose of removing the carbonic anhydride from water-gas.—A. R. L.

### PATENTS.

*Improvements in and in the Mode of Utilising the Pressure in Cylinders or Reservoirs of Compressed Gases in the Application or Employment of such Gases.* The Manchester Oxygen (Bris's Patent) Co., Ltd., and W. M. Jackson, both of Manchester. Eng. Pat. 10,554, May 30, 1893.

THIS invention has reference to apparatus for utilising the pressure in cylinders containing compressed oxygen, to induce or draw in a stream of gas, such as coal-gas, so as to mix with the oxygen and thereby give a mixed jet for producing the oxy-hydrogen flame. The apparatus consists of an inner tube tapering to a very fine outlet, through which oxygen is passed under pressure, thereby inducing a current of coal-gas from the reservoir connected to the outer and enveloping cone and delivering the mixed jet into a suitable outlet pipe, as in the manner of an ordinary injector; the outlet pipe conducts the gases to a mixed jet burner. To prevent the fine outlet of the oxygen pipe being blocked up, one or more layers of gauze are placed over the oxygen inlet, and the gases, after mixing, are passed through a plug of fibrous material to prevent noise or vibration due to the injector acting injuriously upon the flame.—E. G. C.

*Improvements relating to Incandescence Bodies for Incandescent Gas Lamps.* G. A. E. Schneider, Chemnitz, Saxony. Eng. Pat. 12,029, June 19, 1893.

THIS invention relates to the "hoods" of incandescent gas lamps, and consist in using a fabric of incombustible threads. The hood made from this is repeatedly dipped into a suitable liquid, in which absorbent, combustible, finely-divided fibres are suspended, whereby it is coated with a layer of them. It is then impregnated, dried, and finally burnt. The hood thus produced has, in addition to the usual skeleton of ashes, a fire-proof skeleton to support them.—R. E. P.

*Improvements in Ovens or Furnaces for Drying and Coking Peat Briquettes and the like.* E. Stauber, Hamburg, Germany. Eng. Pat. 14,203, July 22, 1893.

THE drying oven is constructed of iron, and has a feed hopper A, and an outlet B on top. The discharge-opening C and the air-inlets D are at the bottom. The briquettes

Fig. 1.

are fed in at A, and fall on to a hot plate E, along which a conveyor band F traverses them. They then fall on to a second hot plate E', are moved back along this by a second conveyor band F' until they fall on to the third hot plate, and so on, being finally delivered through C, thoroughly dried. The dried briquettes then go to the coking oven shown in Fig. 2, into which

Fig. 2.

they are fed through the hopper 1 until the coking space 3, which is closed by the plate 2, is filled. The hopper is then closed air-tight. The fire-box 4, filled with glowing fuel, is next pushed back into the fire-space 3, the disc 2 is withdrawn, and the coking commences. The gases drawn off are exhausted through the outlets 6, 7, 8, by the ventilators 9. After the removal of all moisture, air inlets, constructed on the exterior of the furnace, are from time to time opened. The outer air enters through small connecting tubes 10 in the caps 11, which are fastened to the central outlet 6. The air here mixes with the water-gas produced in the furnace, causing it to ignite and complete the coking process. The products of combustion pass along 6, 7, and 8 into the outside air. The fire-box being at this time drawn out by rotating the shaft 14 and the attached vanes 13 a quarter of a turn, the coked material is from time to time withdrawn into waggons 12. By these means the whole contents of the furnace are prevented from tumbling out when a waggon load is being withdrawn.

—R. B. P.

*Improvements in Apparatus for Washing and Purifying Gas.* F. D. Marshall, Copenhagen. Eng. Pat. 22,576, November 24, 1893.

The improved apparatus is two-chambered, the roof of the lower chamber, *a*, Fig. 1, being the floor of the upper one, *c*. An axial vertical tube, *d*, puts the two chambers in communication; the lower opening of this tube is flush with the roof of the lower chamber, while the tube projects from the floor to about one-third the total height in the upper

chamber. The lower chamber is about one-third full of water, and the pipe, *b*, leading the gas into the apparatus, dips into this water. The annular space between the projecting vertical tube and the walls of the upper chamber is also partly filled with water, and into this water dips a bell-like structure *f, g*, suspended against a counterpoise

Fig. 1.

Fig. 2.

Fig. 4.

Fig. 5.

Fig. 3.

outside the apparatus, the connection between bell and counterpoise being a rod *s*, attached to the top of the bell and passing through a stuffing box in the roof of the upper chamber; the rod is attached to a flexible connection, which, after passing over a pulley *t*, suspends the counterpoise.

The bell itself is a highly complicated structure. It is double walled, each wall being built up of eight rectangular structures, joined together by their side edges; while the two walls so built up are joined to the single top plate, which completes the bell. A horizontal section of the bell therefore shows two regular and concentric octagons.

Each of the 16 rectangular structures is composed (see Figs. 2, 3, 4, and 5) of an outer plate *g*, perforated by eight vertical slits, and an inner plate *n*, similarly perforated. The perforations *p* of the outer plate alternate with those, *o*, of the inner plate. Between the two plates are a series of channelled bars *j, j* (riveted to the cross-bars *k, k*, which are attached to *g*), and a series of metallic strips *l, l*, alternating with the bars *j, j* (the strips are held in position by the angle-iron *m*, which is riveted to the framing *f*). The outer plate *g*, with its cross-bars *k, k* and their attached channelled bars *j, j*, can slide in and out under the guides *h, h* and *i*.

The action of the apparatus is as follows:—Gas enters the lower chamber, passing through the water therein and losing, therefore, part of its tar and ammonia; from the lower chamber it passes by the vertical tube to the inside of the bell, then through the apertures *o* (see Fig. 5) of the inner plates, where each stream is immediately divided into two by the strips *l*. The divided streams next pass through the narrow slits existing between *l, l*, and *g*, and thence by the apertures *p* of the outer plate, the gas reaches the space between the outer and inner walls of the bell. The outer

wall is similarly penetrated, and, passing through the water, the gas reaches the upper part of the upper chamber, in the wall of which is the exit pipe A.

The bell is immersed to a great or small extent in the water of the upper chamber, according as the pressure of the gas overpowers the counterpoise.—E. R. B.

*Improvements in Methods and Apparatus for Generating Gaseous Fuel from Solid Hydrocarbonaceous or Carbonaceous Material.* B. H. Thwaite and G. Threlfall, London. Eng. Pat. 1690, January 26, 1894.

THE inventors describe a new form of fuel gas generator which, while it permits the use of "slack," carrying as much as 30 per cent. of volatile constituents, on the one hand, or "breeze," carrying as much as 25 per cent. of incombustible matters, on the other, and allows of the recovery of much of the radiated heat, produces permanent gas, suitable for internal combustion engines, &c.

Two generators, placed side by side and joined by three connections, as shown in Fig. 1, are employed. By means of an air-blast the fuel is rendered incandescent in each and then a definite cycle of gas manufacture is established, which consists in making the gas generated in the first generator descend through the incandescent fuel in the second, so that any steam or hydrocarbons still remaining in the gas produced by the first generator, is decomposed into H and CO in the second. The gaseous current is then reversed, the second generator now acting as crude gas producer, while the first ensures the permanent character of the gas. Throughout the process the direction of the gas current is reversed at short intervals of time. In Fig. 1, A and B are the two generators, and C, E, and K, J, Z, D, the three connecting conduits with their valves. The chamber D

Fig. 1.

of the middle conduit contains the reversal gear, consisting of two bells, X and Y, suspended each over one of the exit passages Z Z of the respective generators, and the final gas exit, 17.

The bells forming the gas-reversal valves are suspended by chains attached to two projections, 8, 8, on the periphery of the wheel 7. The axle of this wheel carries a rocking

lever, 20 in Fig. 2, to the ends of which are suspended two accurately balanced pyramidal brackets, 18, capable of being filled from the water supply pipes, 29, 30, above them. The flow of water is controlled by the three-way cock, 28, which is operated, through the lever 27 and the link 26, by the rocking lever 20. The air-reversal valves are similarly operated by another link and lever (Fig. 1) from the rocking lever. The motion of the latter is determined by the fall of the upper bracket, which takes place immediately the amount of water it has caught overpowers the spring catch, 21, which retains it; the lower bracket is then swung up and caught by its spring catch (20), and water commences to flow into it, while, simultaneously, the direction of the water-supply alters.

Other special features of the apparatus are, 1 (see Fig. 4).

Fig. 2.

*Improvements in or connected with Hydrocarbon Burners.*  
A. Kiesow, London. Eng. Pat. 3319, February 15, 1894.

This invention relates to an improved method of inserting the wick into a lamp burning fluid hydrocarbons, and to an improved method of securing the burner to the vessel containing the fluid.—R. B. P.

*Improvements in and relating to the Purification of Gas.*  
E. Fleischhauer, Gotha, and M. Bernstein, Berlin. Eng. Pat. 4719, March 6, 1894.

This patent principally relates to a new apparatus for removing tar and ammonia from coal-gas. In the figure, A B is a vessel partly filled with water, and with gas inlet and outlet, *m* and *s* respectively; it also contains the horizontal shaft *c* driven by the pulley *d* and carrying four discs, *e*<sup>1</sup>

to *e*<sup>2</sup>. The second and fourth of these discs carry a series of pockets, *i*, *l*, having one side open, and sets of perforations, *g*, *h*, on the other sides: a set of pins or stops, *k*, keep the discs 1 and 3 apart from 2 and 4 respectively. The stop *r* prevents gas passing, above the discs, from the entrance to the exit side of the apparatus, without being intimately engaged by the discs.

The action of this part of the apparatus is as follows:—Any gas in A B is caught up by the pockets of disc *e*<sup>1</sup>, which is revolving rapidly, and is driven by centrifugal force partly through the perforations at *g* and partly through those at *h*. That passing through *h* impinges against the casing of the apparatus, while that passing through *g* impinges against disc *e*<sup>2</sup>, and thus by centrifugal force is driven through the narrow spaces between the pins *k*, and impinges against the casing. Having arrived in the space between the pairs of discs, it is caught up by the pockets of *e*<sup>2</sup>, and is treated by *e*<sup>2</sup> and *e*<sup>3</sup> as it was by *e*<sup>1</sup> and *e*<sup>2</sup>. Gas and water-sprays are therefore being constantly dashed against the sides of the apparatus, and the tar, which is constantly being deposited on the walls, is continually being washed off. The object of the hurdle *p* is to keep the bottom part of the liquid contents from agitation, so that tar which has sunk below this level may quietly separate out. The gas now passes by *s* to the second part of the apparatus.

This consists of a vertically-adjustable shaft *x*, rotating in upper and lower bearings *z*, and carrying seven pans *u*, the whole being enclosed in a casing *w*, which

resembles a series of bottomless pans joined together, and which communicates at the bottom with a reservoir *v* partly filled with water.

Gas entering by *s* passes through *v* into *t*, and then between the rotating pans and the casing to the exit *e*; its upward passage is greatly assisted by the presence, on the under side of the pans, of deep radial ribs *u*<sup>1</sup> reaching nearly to the casing, which have a fan-like action on the gas when the shaft is rotated. The pans are kept supplied by water through *2* and *t*<sup>1</sup>, which is constantly being flung against the sides of the casing, partly as consequence of the rapid rotation of the pans, and partly owing to the action of certain wings *y*, which project downwards from the horizontal parts of the casing into the water in the pans, in a slanting direction, opposite to that of the rotation. This agitation and sub-division of the water is further aided by the radial partial partitions *3* in the interior of the pans.—E. R. B.

### III.—DESTRUCTIVE DISTILLATION. TAR PRODUCTS, Etc.

*The Commercial Position of the By-Products of Gas Manufacture.* P. Mallet. Bull. Soc. Chim. 9, 218—220.

The most important factor influencing the commercial value of the by-products from the manufacture of gas is the rapidly increasing number of coke ovens at work. In 1893 there were 210 of these ovens in use in France, capable of carbonising from 180,000 to 190,000 tons of coal per annum; in England there were about 413, and in Germany more than 1,250. Were, however, the whole of the coal required for the preparation of the coke used in metallurgical operations treated in ovens, the quantities of by-products turned out would rival and sometimes exceed the amounts produced by gas manufacturers; for in France  $1\frac{1}{2}$  million tons of metallurgical coke are used per annum, which would yield 18,000 tons of ammonium sulphate, 44,000 tons of tar, and 3,000 tons of light oils; while Germany requires 74 million tons of coke, equal to 110,000 tons of sulphate, 375,000 tons of tar, and 10,000 to 30,000 tons of light oils.

Tar itself is likely to continue to fall in value, chiefly owing to the progress that has been made in designing furnaces capable of burning economically fine coal alone, this having resulted in a diminished demand for pitch for briquette manufacture. Almost all the tar products, including benzene and anthracene, will in all probability become still cheaper than they are at present, with the exception perhaps of the heavy oils, for which the railway companies keep up a constant demand for preserving sleepers, the use of copper and zinc salts for this purpose dying out by reason of the higher cost and inferior results. At the same time, the attempts that are being made to replace wooden sleepers by iron must be carefully watched.

Of ammoniacal products, the trade done in liquefied ammonia, ammonium chloride, and nitrate is very insignificant, while the price of aqueous ammonia depends on the ammonia-soda trade. In 1891, 116,323 out of 196,583 tons of carbonate of soda were made in France by this latter process, requiring, on the average of 8 kilos. of ammonia per ton of soda, 930,000 kilos. of ammonia. Thirty-five years ago ammonium sulphate was used only as a source of ammonia alum, and it continued to be exported from France till 1868. Then its use as a manure began to spread, and the price rose from 28 to 50 francs per 100 kilos., where it remained till 1882, when the competition of the South American sodium nitrate became noticeable. In 1873 the total exports of nitrate were 285,000 tons, and in spite of a tax of 6.24 f. per 100 kilos. imposed by Chili in 1880, this amount has risen to 932,000 tons in 1889, while the price has fallen in the same time from 44 f. to 19½ f. Legrand has calculated that Belgium consumes per unit of surface six times more nitrate than Germany, nine times more than France, and 11 times more than England, and that the present requirements are only  $\frac{1}{10}$ ,  $\frac{1}{30}$ , and  $\frac{1}{100}$  respectively of what they should be were the soil properly manured; but the deposits of Tarapaca and Acatama are estimated to contain 250 million tons, and this amount at a very favourable computation will last more than another 40 years, so that the only hope for better prices in the sulphate market lies in a possible union between the manufacturers.

Coke is after all the most important by-product, its value reaching half that of the gas made from the same quantity of coal. Thirty years ago there was no domestic outlet for coke at all, and it was hardly used in any manufacturing operation except lime-burning; now, however, improved forms of warming and ventilating stoves are being brought out, constructed to burn either coke or anthracite (and the latter is too expensive to use in France, costing, as it does, in Paris, without tax, 50 f. per ton), so that its use is constantly spreading among private consumers. It is being employed, too, in blast furnaces, many in the Loire district being run with 30 to 40 per cent. of coke. Outlets are also being found for the smalls, some furnaces being constructed which will burn without a blast up to 70 per cent.

of the fine powder. The outlook, therefore in this department is favourable, the chief obstacle to any increase in price being the gas-makers themselves, who are using a smaller proportion of their make, and consequently throwing more on the market. T. H. L.

*New Apparatus for Fractional Distillation.* E. Vazeille. Bull. Soc. Chim. 11—12, 1894, 289—292.

See under XVIII., page 704.

*The Removal of Sulphur from Mineral Oils at Chicago.* —Biche and —Roume. Annales des Mines, 5, 95, 1894. Proc. Inst. Civil Eng. 1894, 116, 187—89.

At the Standard Oil Company's refinery at Whiting, near Chicago, a new establishment covering 300 acres and employing 1,000 men, the crude oil of Lima, in Ohio, which was formerly used only as fuel, on account of its disagreeable odour and the sulphur gases evolved in burning rendering it unfit for illuminating purposes, is now refined by methods which destroy the sulphur compounds, leaving the hydrocarbon oils unaltered. These oils are very variable in composition, their density ranging from 0.816 to 0.950, their average yield on treatment being—

Naphtha and burning oil .....	56.88
Heavy oils .....	32.00
Residues .....	9.50
Water .....	0.75
Sulphur .....	0.65
	100.84

Two processes are used in the treatment, both being based upon the use of cupric oxide as a desulphuriser, a method used in France for desulphurising glycerin in the soap manufactories at Marseilles.

In the first method the crude oil is subjected to distillation without reagents, the oil-vapours from the still being passed into vessels containing cupric oxide, where the sulphur is separated as cuprous sulphide, while the cleaned oil passes on to a large tubular cast-iron condenser cooled with water, where it is collected for further treatment. In this way the whole of the volatile contents of the oil are subjected to the desulphurising treatment.

In the second method, which, in spite of its involving a double operation, is now becoming general, the first distillation is conducted in the ordinary way, the lighter products, spirit and burning oil, being kept apart and subsequently transferred to another still provided with a stirring apparatus, in which they are heated with finely-divided oxide of copper, the contents being kept intimately mixed by the agitator. This second distillate is perfectly free from sulphur, showing no trace of colour in a solution of acetate of lead, which is readily blackened by the crude oil, as well as by the first distillate, and as burning oil it is equal in quality to that obtained from Pennsylvania petroleum, as it burns without a sulphurous odour and does not blacken the chimney of the lamp.

In conducting the operation it is necessary to use a large excess of cupric oxide, otherwise the pipes of the still are rapidly corroded, even when heavy steel ones are substituted for those of sheet iron ordinarily used.

The residue in the still consists of a mixture of tar and cuprous sulphide. It is drained and finally squeezed on a press or roller mill, giving a thick fluid, which yields a solid cake in the filter-press. The pressed cake is broken up and heated in an inclined cylindrical furnace lined with fire-brick, with a fireplace at the lower end, the heat being just sufficient to start the combustion of the mass, which is continued by the oxidation of the sulphur, the final product being a finely-divided powder of cupric oxide, which is returned for use to the refinery after being dried in thin layers under shed in the open air.

About 10,000,000 barrels of Lima oil are refined annually, a further quantity of about 30,000 being treated in the smaller establishment at Lima, where the method was originally developed.

## PATENTS.

*Improvements in the Distillation of Petroleum.* J. A. Wanklyn and W. J. Cooper, both of New Malden, Surrey. Eng. Pat. 4097, February 24, 1893.

In this apparatus the boiler, or still, has a tall trunk, rising up to the condenser C. At its upper end there are a number of outlets, each connected to a tube in the condenser, which

Fig. 1.

is of the surface-condensing type. Its tubes, which correspond in number to the outlets from the still trunk, slope downwards from their inlet ends, and discharge into a common receiving chamber R. From the latter an outlet pipe Z passes downwards, of sufficient length to get a column of liquid 40 ft. high. By means of two cocks, one on the

Fig. 2.

top of the receiving chamber and the other at the lower end of the outlet pipe, the distillation can be carried on at all pressures from an approximate vacuum to that of the atmosphere. This form of outlet enables the apparatus to create and maintain its own vacuum. The cooling medium used in the condenser is the liquid to be distilled, which is thus heated to a certain extent before it is fed into the still.

*An Improved Artificial Asphaltum or Pitch, and Process for Making same.* R. Hadden, London. From G. R. Anderson, A. H. Shotton, W. Kochler, and C. H. Dorer, all of Cleveland, Ohio, U.S.A. Eng. Pat. 9550, May 12, 1893.

This invention relates to the production of artificial asphaltum, or pitch, from hydrocarbon oils or their products (especially the heavy distillates and the residuum from distillation, which may or may not have been previously treated with acids) by the addition of resinous substances, preferably those from the pine tree, and, if sufficient acid is not present, the addition of acid, preferably sulphuric acid, and subjecting the whole to heat and partial distillation. The amount of each ingredient is determined by the qualities the final product is to have, and all proportions are claimed.

—R. B. P.

## IV.—COLOURING MATTERS AND DYES.

*Acetine.* E. Kopp and E. Grandmougin. Bull. Soc. Ind. Mulhouse, 1894, 112—116.

*Manufacture.*—Heat together in an enamelled copper vessel, by means of an oil-bath, 60 parts of glycerol and 82 parts of glacial acetic acid for 12—15 hours at 120° C., then gradually raise the temperature to 160° C. to drive off excess of acetic acid. The product consists of 93 parts of concentrated acetine, a dense liquid smelling more or less strongly of acetic acid, and varying in colour from pale yellow to dark brown according to the glycerol employed.

*Valuation.*—It is evidently important that the union of the glycerol with the acetic acid should be as complete as possible; in other words, that the acetine should contain the maximum of combined, and the minimum of free acetic acid. These two factors are therefore estimated. The density, which varies from 1.1608—1.1896 may serve as a rough indication, the more free acetic acid present the less the density. The estimation of free and combined acetic acid is thus carried out:—50 grms. of acetine are diluted with water to 500 cc. In 50 cc. of this solution determine the free acetic acid with normal caustic soda and phenolphthalein indicator. Then to 10 cc. of the acetine solution add 15 cc. normal soda, heat to boiling, and boil for five minutes, then after dilution estimate excess of soda with normal acid. For example, if 4.5 cc. normal acid are required, the combined acetic acid corresponds to 15—4.5=10.5 cc. of normal caustic soda (1.5 cc. being the amount necessary to neutralise the free acid of the 10 cc.) = 9 cc. normal soda, which, for 50 grms. acetine, would mean 27 grms. combined acetic acid, or 54 per cent. It is possible also to estimate the glycerol, but the process is too long for practical use, and is, moreover, unnecessary, the above estimations indicating sufficiently the value. The following table gives the results of analysis of three samples:—

No.	Density.	Acid, Free.	Acid, Combined.	Remarks.
		Per Cent.	Per Cent.	
I.	1.1774	9.2	46.0	Acetine obtained with above proportions of glycerol and acetic acid.
II.	1.1896	6.98	55.7	.. ..
III.	1.1608	23.0	43.5	Almost colourless; smells very strongly of acetic acid.

Sample II. is good, I. of medium quality, III. contains too much free, and too little combined acetic acid.

*Employment.*—As a solvent, especially for basic colours, e.g., Induline and Perkin's violet. To dissolve induline, heat with the acetine in a copper vessel, boil for two hours, allow to cool, and pass through a silk filter.

*Supplementary Note.*—Ethyl- and methyl-tartaric acids, which are used for the same purpose as acetine, are valued in much the same way, viz., by estimating free and combined tartaric acid. Acetine is to be preferred as a solvent, because acetic acid injures the fibres less than tartaric acid.—R. B. P.

*Oxindophenolic Colouring Matters from Gallanilide and Galloparatoluide.* P. Cazeneuve. Bull. Soc. Chim. 11, 1894, 85—87.

In a French patent of July 27th, 1877, Durand and Huguenin describe the preparation of a blue colouring matter obtained by the action of nitrosodimethylaniline on the condensation product of tannic acid and aniline. The olive-green product insoluble in water is converted into the sulpho-derivative by boiling with alcohol and sodium bisulphite, or by the action of fuming sulphuric acid. Both the sodium and ammonium sulpho-salts are valuable blue dyes, sold under the name of "Gallic blue" or "Tannin indigo." This compound is undoubtedly a derivative of gallanilide.

The author has obtained a similar compound from gallotannolide. The first product is an insoluble green crystalline substance; the ammonium and sodium salts of the sulpho derivative are blue colouring matters closely resembling those from gallanilide in tint and character.

The author considers these compounds to be analogous in constitution to indophenol. For the gallanilide derivatives the formula would be—

and—

(See under XX., page 755)—L. T. T.

### 2,3-Naphthylene Diamine. P. Friedländer and S. v. Zakrzewski, Ber. 27, 761—765.

THEORETICALLY 10 different naphthylene diamines can exist, of which at present only 9 have been obtained. The authors have prepared the missing isomide (2,3), employing as starting-point  $\beta$ -naphthol-disulphonic acid R, which (according to Pfitzinger and Duisberg) has the constitution 2,3,6. This was fused with 5—6 times its weight of caustic soda at  $200^\circ$ — $220^\circ$ ; the termination of the reaction is marked by thinning of the melt, and cessation of foaming. On solution in water, nearly neutralising, filtering, and faint acidulation of the filtrate, shining crystals separate, consisting of the sodium salt of dihydroxynaphthalene monosulphonic acid. On boiling this with mineral acids the sulphonic group is removed and a dihydroxynaphthalene results; since this is not the well-known 2,6 modification, it follows that it must be the 2,3. Finally, by heating this with ammonia to  $240^\circ$  for 12 hours, the hydroxyl groups are displaced by amidogen, and 2,3-diamidonaphthalene results. This melts at  $191^\circ$  and is readily soluble in alcohol, extremely so in ether, but only with difficulty soluble in water. The hydrochloride is easily soluble in water, only sparingly soluble in excess of acid. With 1 molecule of a diazo-compound it combines, forming a red diazo dyestuff. With acetic anhydride it forms a diacetyl derivative,  $\text{C}_{10}\text{H}_6(\text{NH}(\text{CO}.\text{CH}_3))_2$ . When 2,3-dihydroxynaphthalene is heated with ammonia to a lower temperature than that requisite to form the diamine, 2,3-amidonaphthol results (10 parts concentrated ammonia at  $135^\circ$ — $140^\circ$  for some hours); this melts at  $234^\circ$ . 2,3-naphthylene-diamine does not form a tetrazo derivative with nitrous acid, but produces a weakly basic azinide,  $\text{C}_{10}\text{H}_6\text{N}_3$ . Fusion with oxalic acid forms dihydroxynaphthylquinoxaline; with dihydroxytartaric acid in hydrochloric solution, naphthyl-2,3-quinoxaline orthodicarbonic acid is produced as a nearly insoluble precipitate.—C. R. A. W.

### The Manufacture of Copper-plate Ink. A. M. Villon. Bull. Soc. Chim. 9, 1893, 929—936.

THE inks employed in printing from a copper plate are compounded in a somewhat similar manner to those used

by letterpress printers, but the "varnish" is usually thinner and lampblacks are replaced by other forms of pigment. Copper-plate varnish, or "burnt oil," is prepared in three qualities, thin, medium, and strong. According to the older methods of manufacture the raw linseed oil was heated in a movable pot, set fire to, and allowed to burn for five minutes, well stirred, removed from the fire, and extinguished by means of a closely-fitting lid. Several slices of stale bread were then successively introduced with a pair of tongs and stirred round in the oil until they were browned but not burnt by the heat, this device—which is still believed in by almost all practical varnish makers—having for its object to remove the "greasiness" of the oil. Occasionally peeled onions were used instead of the bread to the same end, although the action of either substance on the oil is quite unknown. This operation being over, the oil was either allowed to cool down, or else inflamed again for a few minutes, put out, stirred up, and again set light to, till the requisite strength was reached, the strong varnish having, when cold, a viscosity resembling molasses. In large modern ink-works the linseed or nut oil is first refined or "freed from grease" by treatment with nitric acid or magnesia, then 200 litres are warmed slowly up in a pan, so that after three hours the temperature is  $180^\circ \text{C}$ , 500 grms. of potassium bichromate in fine powder are added, and the heat raised to  $300^\circ$ ; when the frothing is over it is increased to  $315^\circ$ — $320^\circ$ , and 500 grms. of Prussian blue ("pencil blue") put in, and the heat maintained—for the strong varnish—half an hour. For the medium varnish the oil is kept at  $300^\circ$ — $305^\circ$  for five minutes only, and for the thin it is not allowed to exceed  $275^\circ$ , where it is maintained from 15 to 30 minutes. The best varnishes are made from nut oil, but sufficient viscosity for the strong variety cannot be obtained without the addition 12 to 15 per cent. of linseed oil. Oxygen may be employed instead of fire heat, by warming either nut or linseed oil, or both together, to  $180^\circ$  and passing over them a current of the gas. However prepared, the varnishes must be allowed to settle for a month.

As black pigments, instead of the ordinary lamp- or "vegetable" black, the following substances are employed:—*Frankfort-black*, prepared by calcining the refuse from wine-making; *fish-black*, from oyster shells, &c.; *cork black*, and "*German*" *black*, made from a mixture of these substances together with greasy bones. The carbonisation takes place in specially designed retorts, holding from 40 to 50 kilos, each, set on tiles over the hearth, and so arranged that the acetic acid and other liquid products can be collected, and the permanent gases burnt underneath. The resulting blacks are ground with water, carefully levigated, and moulded into "drops." In compounding the inks, mixtures of these pigments are employed, as each one has a special shade of its own, a good mixing being as follows:—*Frankfort-black*, 50 parts; *bone-black* and *fish-black*, 25 parts each. On the small scale, the ink is often made with a muller and stone, the black being moistened with a few drops of thin varnish, and when thoroughly mixed, strong varnish added until the proper consistency is reached, blue being put in if desired. On a larger scale 1,000 parts of thin varnish are heated in a steam-jacketed pan provided with a mechanical agitator, 50 parts of "pure" blue added, the temperature raised to  $150^\circ \text{C}$ , and, after half an hour's stirring, 25 parts of rosin soap thrown in. The mass is cooled over night, and 500 parts of the previously-described mixed black and 200 of strong varnish mixed in, and the whole finally ground on granite or iron roller mills. The author quotes a number of formulae for the manufacture of different grades of ink, the following being specially recommended as having a deep black colour, free from "bronze" and keeping well. Thin nut-oil varnish, 1,000 parts; strong varnish, made from 50 per cent. of nut oil and 20 per cent. of linseed oil, 200; Carbauba wax, 25; paraffin, 35; rosin soap, 25; Paris-violet, 0.5; "pure" blue, 10; cork black, 100; blood black, 50; *Frankfort black*, 20; and *bone black*, 150 parts. The violet is dissolved in alcohol before being added to the hot varnish, and the blue is ground and put through a silk sieve.

## PATENTS.

*The Production of Colours on Fibres.* H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 11,891, June 16, 1893.

THE colours are produced from the dyestuffs referred to in Eng. Pats. 8530 of 1890, 9636 of 1891, 22,641 of 1891, 11,395 of 1892, and 15,439 of 1892 (this Journal, 1893, 238, 593, and 754), by diazotising them on the fibre and subsequently treating the fabric in a hot acid or alkaline bath. Similar shades are obtained if instead of diazotising and subsequently treating the dyed fabric as above, it is subjected to the action of weak oxidising agents. For instance, the colouring matter from one molecular proportion of tetra-*o*-ditolyl chloride and two molecular proportions of 1,3'-*n*-naphthylamine sulphonic acid is dyed on cotton in a bath containing sodium sulphate and sodium carbonate. After rinsing, the dyed fabric is immersed in an acidulated bath of sodium nitrite for about half an hour, when the bluish-black colour is turned to violet-brown. The material, after washing, is then heated at about 50° C. in a 5 per cent. bath of sodium carbonate, when a cutch-brown shade is produced fast to washing. A similar shade is obtained by dyeing the fabric as above and then treating it for some time in a weak bath of chloride of lime. The strength of the bath is about 0.25° B. and the temperature 30°–40° C. The products obtained are supposed to be azoxy compounds.

—T. A. L.

*Improvements in the Manufacture of Colouring Matters.* H. H. Lake, London. From A. Leonhardt and Co., Mülheim-on-the-Maine, Germany. Eng. Pat. 12,323, June 22, 1893.

By condensing *m*-amido-*p*-cresol, 1,2,4- $C_6H_3(CH_3)_3NH_2.OH$ , with formaldehyde, preferably in presence of a mineral acid, it yields diamido-dihydroxyditolylmethane, which, on treating with a dehydrating agent, such as sulphuric acid, and subsequently oxidising, is converted into a colouring matter. A colouring matter of the rhodamine series is also produced by heating *m*-amido-*p*-cresol, and phthalic anhydride in presence of sulphuric acid. The following quantities are employed for the preparation of the methane derivative. About 12 kilos. of *m*-amido-*p*-cresol are dissolved in 200 litres of water, containing 14 kilos. of 30 per cent. hydrochloric acid, and treated with 3.8 kilos. of a 40 per cent. formaldehyde solution. After standing some time, the solution is heated to 60° C., a small quantity of sodium carbonate is added to precipitate impurities, and the diamido-dihydroxy-ditolyl methane is precipitated from the filtrate by adding sodium carbonate. The product, when crystallised from spirit, melts at about 225° C. By heating it with five times its weight of sulphuric acid to 100° C., it forms a yellowish-red melt, and when a sample supersaturated with caustic soda gives no precipitate on adding acetic acid, it is poured into 20 times its weight of ice water, when most of the condensation product is precipitated. The mother-liquor is mixed with salt and zinc chloride, and oxidised with ferric chloride or potassium bichromate. The colouring matter is purified by dissolving in water and reprecipitating. The orange-red colouring matter from *m*-amido-*p*-cresol and phthalic anhydride is obtained by heating together 1 kilo. of the latter, 2 kilos. of the former, and 8 kilos. of sulphuric acid to 160° C. for several hours. The melt is poured into 100 litres of water, the whole boiled up and filtered, when the greater part of the colouring matter crystallises out on cooling, the remainder being precipitated with salt.

—T. A. L.

*The Manufacture of New Leuco Compounds and the Production of Colouring Matters therefrom.* H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 13,394, July 10, 1893.

THIS specification describes another method of obtaining the dyestuffs referred to in Eng. Pat. 11,876 of 1892 (this Journal, 1893, 595). The methods now mentioned are for

the production of the leuco derivatives of the above compounds, and these are obtained by condensing the alkylated diamido-diphenyl methanes or homologues thereof with oxazine dyestuffs, or else by condensing the alkylated diamido-benzhydrols with the leuco derivatives of the oxazine dyestuffs. The two following examples illustrate the production of these leuco derivatives. (1.) 31 kilos. of new blue R and 26 kilos. of tetra-methyl-diamido-diphenylmethane are dissolved in 250 kilos. of alcohol and kept at 80° C. for several hours. The leuco compound produced can be precipitated by adding water. (2.) The same quantities of new blue R and alcohol are taken, and zinc dust and hydrochloric acid are added until the solution is decolourised. The filtered solution is then mixed with 27 kilos. of tetra-methyl-diamido-benzhydrol, and heated at 70°–80° C. for 12 hours, when the reaction is complete, and the leuco compound is precipitated by water. The leuco compound produced according to either of the above examples is mixed with 50 kilos. of acetic acid and 125 kilos. of a 20 per cent. lead peroxide paste. Sulphuric acid is then added to precipitate the lead, and after filtering off the lead sulphate the filtrate is mixed with 25 kilos. of zinc chloride and sufficient salt to precipitate the dyestuff, which can be purified by dissolving and reprecipitating it. The colouring matter thus obtained is found to be identical with that described in the first example of Eng. Pat. 11,876 of 1892. By using twice the quantity of lead peroxide paste and working the product up as before, a product is obtained which is identical with that mentioned in example 2 of the before-mentioned specification.

—T. A. L.

*Manufacture of Colouring Matters by Reduction of Tetra-nitro-anthrachrysone and Dinitro-anthrachrysone-disulphonic Acid.* O. Inray, London. From "The Farbwerke vormals Meister, Lucius, and Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 13,395, July 10, 1893.

THESE colouring matters, which dye mordanted wool green and blue shades, are obtained from tetra-nitro-anthrachrysone and dinitro-anthrachrysone disulphonic acid by reduction in an alkaline or acid solution. The following substances may be employed as alkaline reducing agents:—Sodium or ammonium sulphide, glucose, sulphate of iron, and similar reagents, and the method employed is to dissolve the tetra-nitro-anthrachrysone in about 20 times its weight of water containing rather more carbonate of soda than corresponds to four hydroxyl groups. Sodium sulphide (for four nitro groups) is then added, and after standing some time the solution is warmed on the water-bath for an hour. After cooling, the colouring matter is precipitated by salt or acid and is used for dyeing as a paste. It dissolves in hot water with a blue colour, in dilute caustic soda with a violet, and in ammonia with a blue colour, and is precipitated easily from these solutions by salt or acid. The solution in concentrated sulphuric acid is violet. On chromed wool it gives deep green to blackish-green shades fast to soap and fulling. In order to carry out the reduction in an acid solution the tetra-nitro-anthrachrysone is mixed with 30–40 times its weight of diluted hydrochloric or sulphuric acid, and rather more zinc is added than is required for four nitro groups. After about 12–24 hours the colouring matter separates in flakes, and the reaction is completed by warming the melt on the water-bath, when the dyestuff is filtered off and purified by precipitating its dilute alkaline solution with salt. The colouring matter forms a greyish-blue paste, which dries to a black powder with a metallic lustre, dissolving in concentrated sulphuric acid with a brownish-red colour. On chromed wool the shades range from bluish-grey to blue, and are said to be perfectly fast to fulling, soap, and light. In a similar manner colouring matters can also be produced from dinitro-anthrachrysone disulphonic acid. These, however, are also capable of dyeing unmordanted wool from an acid bath on unmordanted wool are blue, whilst on chromed wool they are green, and on wool mordanted with alumina they are bluish-green. The colouring matter obtained by employing acid reducing agents gives pure violet shades on

unmordanted wool from an acid bath, on chromed wool pure blue shades, and on alumina mordants the shade is violet-blue. On mordanted wool the colours are fast to fulling.—T. A. L.

*Improvements relating to the Production of Amidophenol and Amidocresolsulpho-Acids, and to the Manufacture of Colouring Matters therefrom.* H. H. Lake, London. From K. Ochler, Offenbach-on-the-Maine, Germany. Eng. Pat. 13,402, July 10, 1893.

The sulphonic acids referred to are obtained by heating the disulphonic acids of aniline and of *o*- and *p*-toluidine with caustic alkalis to 200–230° C. So-called amidophenol sulphonic acid III. is obtained by heating 1 kilo. of sodium aniline *o*-disulphonate with 2 kilos. of 50 per cent. caustic soda lye to 200° C., and precipitating the cold melt with hydrochloric acid. When heated in the water-bath with sulphuric acid it is converted into the isomeric amidophenol-sulphonic acid IV. By fusing 12 kilos. of the acid potassium salt of  $\alpha$ -aniline *m*-disulphonic acid with 36 kilos. of 50 per cent. soda lye for 7 hours to 220° C., the so-called amidophenol sulphonic acid V. is produced by precipitating the melt with hydrochloric acid. In a similar manner the sodium salt of *p*-toluidine disulphonic acid (obtained by sulphonating *p*-toluidine), when heated with twice its weight of 50 per cent. caustic soda lye for 5 hours to 210–230° C., and precipitated with hydrochloric acid, gives amidocresol-sulphonic acid. The same acid is obtained by sulphonating *p*-nitrotoluene, reducing, again sulphonating, and then heating with caustic soda lye. By treating *o*-nitrotoluene in this way an amidocresol sulphonic acid IV. is produced, which on heating with acids gives an amidocresol melting at 157° C. All these compounds will combine with diazo compounds, or the compounds themselves may be diazotised and combined with amines and phenols and their derivatives. The shades of the colouring matters obtained range from scarlet to yellow, whilst the hexazo compounds obtained by combining a diazo compound with the combination from tetrazodiphenyl and amidophenol, or amidocresol sulphonic acid and resorcinol, or *m*-phenylene diamine, gives darker shades.—T. A. L.

*Improvements relating to the Production of Colouring Matters.* A. Ashworth and J. Burger, Bury. Eng. Pat. 13,419, July 11, 1893.

The *o*-nitroso-naphthols,  $C_{10}H_6(OH)NO$  [1.2 or 2.1] or  $\alpha$ -amido- $\beta$ -naphthol, can be condensed with gallic acid or with tannin by warming with sulphuric acid, giving colouring matters which dye on chromium mordants. A solution of 18.8 kilos. of crystallised or 17 kilos. of dried gallic acid or 32 kilos. of tannin in 200 kilos. of sulphuric acid of 66° B. has gradually added to it 17.3 kilos. of  $\alpha$ -hydroxy- $\beta$ -nitroso-naphthalene or  $\beta$ -hydroxy- $\alpha$ -nitroso-naphthalene, the temperature being kept below 25° C. When all is dissolved, the temperature is raised to 40° C. for an hour, then in another hour to 60–70° C., and finally for two hours to 85–90° C. The melt is then cooled down, poured on to ice, and the colouring matter, which precipitates in flakes, is filtered off. When dry it forms a black powder, sparingly soluble in cold water and alcohol, soluble in hot water, and very slightly soluble in ether. The colour in dilute caustic soda is brown, and purplish-brown in sulphuric acid, giving brown flakes on dilution. The colouring matters are used preferably in the form of paste, and when dyed on chromium mordants give brown shades fast to light and soap.

—T. A. L.

*Manufacture of Mordant-dyeing Colouring Matters.* C. D. Abel, London. From "The Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 13,833, July 17, 1893.

The colouring matters described are azo-dyestuffs derived from  $\alpha$ -amido- $\beta$ -naphthol and the two sulphonic acids of the same,  $C_{10}H_5NH_2 \cdot OH \cdot SO_3H$  [1.2.6] and [1.2.7], which contain a hydroxyl and an amido group in the ortho position. The colouring matters obtained by combining diazo and tetrazo compounds with these substances dye wool mordanted

with a chromium salt in shades fast to fulling and light. The diazo compound from 9 kilos. of sulphamic acid is combined with 8 kilos. of 1.2 amido-naphthol dissolved in dilute acetic acid. The colouring matter separates as a blackish-green crystalline precipitate, which dyes wool mordanted with chromium salts a blackish-violet. The diazo solution from 21 kilos. of *p*-nitraniline, in which the free acid has been neutralised by the addition of sodium acetate, is added to a cold solution of 11 kilos. of 1.2.6-amido-naphthol sodium sulphamate. The colouring matter forms a brownish-violet powder and dyes chromium-mordanted wool a deep violet-blue shade. Tetrazo-diphenyl or Triolyl may also be combined with the substances referred to, and in this way mixed diazo compounds may be obtained. In this case, if amido-naphthol be one of the components, either the other component must contain sulphonic or carboxylic acid groups, or the *p*-ol amine must be a sulphonic acid, such as tetrazo-benzene-disulphonic acid, in order that the final product may be sufficiently soluble in water.—T. A. L.

*The Manufacture and Production of New Basic Colouring Matters.* J. Y. Johnson, London. From "The Badische Anilin and Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,014, July 19, 1893.

These dyestuffs are acridine derivatives, and are obtained by alkylating the compound formed by treating fluorescein with ammonia having the empirical formula  $C_{12}H_8N_2O_2$  and the constitution—

On alkylation, by heating with an alcohol and hydrochloric or sulphuric acid at about 100° C., or by carefully treating with an alkyl halogen compound, there results a product of the general formula—

where X represents either hydrogen or an alkyl group, and R is an alkyl group. The bodies obtained are yellow and orange dyes, and the following quantities are given for the production of a dye-stuff which much resembles phosphine. About 1 kilo. of the compound  $C_{20}H_{13}N_3O_2$  is mixed with 10 kilos. of 96 per cent. ethyl alcohol and heated under an inverted condenser on the water-bath, a slow current of hydrochloric acid gas being passed through the liquid until no further production of the dye-stuff takes place. The alcohol and hydrochloric acid are then distilled off on the water-bath and the residue is dissolved in boiling water. After filtering, the dyestuff is precipitated with salt, and is purified by repeating this treatment. The dyestuff is an orange-coloured powder soluble in water and alcohol, giving reddish-yellow solutions having a yellowish-green fluorescence. An autoclave may be used instead of an upright condenser, and by carrying the alkylation further, redder products are obtained corresponding to an alkylation in the amido groups.—T. A. L.

*Improvements in the Manufacture or Production of Colouring Matters derived from Anthraquinone.* H. E. Newton, London. From "The Farbwerke vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 11,315, July 25, 1893.

By the action of sulphuric acid on di-*o*-nitroanthraquinone no valuable dyestuffs have hitherto been obtained, but by the addition of boric acid to the melt, colouring matters which give brilliant shades are formed. It is assumed that the hydroxyl groups in the hydroxyanthraquinone derivatives produced, form boric ethers which are stable in

presence of concentrated or fuming sulphuric acid, even at high temperatures. The following example illustrates the method employed:—A mixture of 10 kilos. of di-*o*-nitro-anthraquinone, 10 kilos. of crystallised boric acid, and 200 to 300 kilos. of sulphuric acid of 66° B. (containing 92 to 93 per cent. of pure sulphuric acid), is heated in an enamelled pan with constant agitation. At about 230° C. a reaction sets in and the temperature rises to 250° or 260° C. The melt is then allowed to cool, poured into 3,000 litres of cold water, boiled up, filtered, and washed free from acid. The dye-stuff so formed consists principally of the hexahydroxyanthraquinone described in Eng. Pat. 17,712 of 1890 (this Journal, 1891, 917), together with a small quantity of a compound containing nitrogen similar to that formed by the action of ammonia on hexahydroxyanthraquinone, as described in Eng. Pat. 8702 of 1891 (this Journal, 1892, 514). It also contains small quantities of the alizarin hexacyanine of Eng. Pat. 4871 of 1891 (this Journal, 1892, 513). On wool mordanted with chromium salts the dyestuff produces intense blue shades. The proportions of the different components vary according to the strength of the sulphuric acid employed: for instance, by using a weaker sulphuric acid than that mentioned above, the product consists almost entirely of hexahydroxyanthraquinone. The same process may also be applied to the isomeric dinitroanthraquinones, or to the crude mixture of nitroanthraquinones obtained by nitrating anthraquinone or anthracene, or the sulphonic acids of these nitroanthraquinones may be similarly treated.—T. A. L.

*The Manufacture and Production of a New Amido Sulpho Acid and of New Azo Dyes therefrom.* J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,678, July 31, 1893.

THE new acid is *m*-phenylene diamine disulphonic acid obtained by the action of fuming sulphuric acid on *m*-phenylenediamine or one of its salts, sufficient acid being taken that at least two molecular proportions of  $\text{SO}_3$  are present for every one molecular proportion of *m*-phenylenediamine. The sulphonation is complete when on combining a sample with diazotised primuline in an alkaline solution an orange-yellow dyestuff for cotton is produced. The presence of *m*-phenylenediamine or of the monosulphonic acid produces a much browner shade. The quantities employed are as follows:—One kilo. of *m*-phenylenediamine hydrochloride is mixed with 5 kilos. of fuming sulphuric acid containing 40 per cent. of free anhydride, and the temperature is gradually raised to 120° C. until the reaction is complete as described above. The melt is then poured into water, limed, filtered, and converted into the sodium salt, or the free acid may be separated by concentrating the solution of the calcium or sodium salt and adding an excess of strong hydrochloric acid. By combining the acid with diazobenzene chloride in presence of sodium acetate a colouring matter is obtained which dyes wool yellow from an acid bath. An orange-yellow colouring matter for unmordanted cotton is produced by diazotising 112 kilos. of primuline with 16 kilos. of sodium nitrite and 140 kilos. of 30 per cent. hydrochloric acid, and combining this with an ice-cold solution containing 55 kilos. of *m*-phenylenediamine-disulphonic acid and 112 kilos. of calcined soda in 700 litres of water. The whole is agitated for 24 hours, and the colouring matter precipitated with salt, filter-pressed, and dried.—T. A. L.

*Improvements in the Manufacture of Colouring Matters.* C. D. Abel, London. From "The Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 14,895, August 3, 1893.

DIRECT-dyeing colouring matters for unmordanted cotton giving very dark shades from a single bath, without the necessity for diazotisation and combination on the fibre, are obtained by combining one molecular proportion of a tetrazo compound with one molecular proportion of the amido-naphthol disulphonic acid of Eng. Pat. 15,175 of

1889 (this Journal, 1890, 854), rediazotising the intermediate compound thus formed, and combining it with two molecular proportions of *m*-tolylene diamine, *m*-phenylene diamine or resorcinol. With regard to the quantities employed, 21.2 kilos. of tolidine are converted into a tetrazoditolyl salt and combined with a solution containing 32 kilos. of amido-naphthol disulphonic acid and 30 kilos. of sodium carbonate. When the formation of the intermediate compound is complete, the product is diazotised by adding 90 kilos. of hydrochloric acid of 20° B. and 7 kilos. of sodium nitrite. The new tetrazo compound thus produced is run into a solution containing 30 kilos. of *m*-tolylene diamine and 30 kilos. of sodium carbonate. After agitating for some time the solution is boiled, the colouring matter salted out, filter-pressed, and dried. It dyes unmordanted cotton a deep black from a soap bath, fast to acids and alkalis.—T. A. L.

*Improvements in the Manufacture of Colouring Matters.* H. H. Lake, London. From A. Leonhardt and Co., Mühlheim-on-the-Maine, Germany. Eng. Pat. 15,080, August 5, 1893.

GREENISH to reddish-blue basic colouring matters may be obtained from *m*-amidoeresol ( $\text{CH}_3 : \text{NH}_2 : \text{OH} = 1 : 2 : 4$ ) or its mono-alkylated derivatives—(1) by reacting with the nitroso or azo derivatives of dialkylated *m*-amidophenol or *m*-amidoeresol on the amidoeresols; (2) by converting the amidoeresols into azo compounds and combining these products with amidoeresols or aromatic amines; and (3) by condensing the amidoeresols with the *p*-nitroso derivatives of aromatic amines, with dichlorimides, with aromatic *p*-diamines or with *p*-amido-azo compounds. The process generally consists in heating the substances together in a medium, such as spirit or acetic acid, and precipitating the colouring matter by means of salt and zinc chloride. For instance, a mixture of 6 kilos. of amidoeresol, 16 kilos. of nitroso-dimethyl-*m*-amidoeresol hydrochloride, and 40 litres of spirit, is heated under a condenser until the nitroso compound has disappeared. The melt is then diluted with 200 litres of hot water, any impurities present are precipitated by adding 7 kilos. of sodium acetate, and, after filtering, the colouring matter, which dyes mordanted cotton blue, is precipitated by adding salt and zinc chloride. As an example of the second method, 6 kilos. of benzene-azo-ethylamidoeresol, 2.5 kilos. of *m*-amido-dimethyl-*p*-toluidine, 4 litres of 30 per cent. hydrochloric acid, and 15 litres of spirit, are heated under an inverted condenser for 24 hours until a sample diluted with water shows the formation of a bluish-violet colouring matter. After dilution with 200 litres of boiling water and addition of 3 kilos. of sodium acetate, the colouring matter is precipitated from the filtered solution with zinc chloride and salt. The process described in Eng. Pat. 13,565 of 1890 (this Journal, 1891, 760) for the preparation of colouring matters from dialkylated amidoeresols may also be applied by substituting for them amidoeresol or mono-alkylated amidoeresol. The following example illustrates the method for obtaining a colouring matter by oxidising a *p*-diamine together with *m*-amidoeresol or its alkyl derivative according to this invention. A solution of 6 kilos. of amidoeresol, 20 kilos. of sodium acetate, and 10 kilos. of *p*-tolylene diamine hydrochloride in 500 litres of boiling water, is gradually oxidised by adding 140 litres of a 15 per cent. ferric chloride solution. After cooling, the liquid is filtered and the colouring matter precipitated as before. It dyes mordanted cotton violet-blue.—T. A. L.

*Improvements in Colouring Matters.* R. G. Williams, Heywood, Manchester. Eng. Pat. 15,509, August 15, 1893.

THIS is an improved method of obtaining colouring matters similar to those produced according to Eng. Pat. 1593 of 1888 (this Journal, 1889, 279). In the present process one molecular proportion of *m*-phenylene diamine or one of its homologues is mixed with two molecular proportions of

sodium nitrite and one molecular proportion of a phenol, resorcinol, or a naphthol, and dilute hydrochloric acid is run into the solution at a low temperature. The colouring matters dye unmordanted cotton from an alkaline or neutral bath. The dyestuff from *m*-phenylene diamine and resorcinol is produced as follows:—A solution of 10.8 lb. of *m*-phenylene diamine, 60 lb. of caustic soda, 14 lb. of sodium nitrite, and 11 lb. of resorcinol in 35 galls. of water is cooled with ice to about 5° C., and dilute hydrochloric acid is run in slowly until the reaction is complete, caustic soda being added from time to time if necessary so as to keep the solution "strongly alkaline during the whole operation." An excess of hydrochloric acid is then added to precipitate the colour, which is filtered off, washed, and dried at a low temperature with sufficient caustic alkali to render it soluble in water. It dyes mordanted cotton brown from an alkaline bath with or without the addition of salt.

—T. A. L.

*Manufacture of Colouring Matters applicable to Unmordanted Fibres or Fabrics.* J. Murray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis," Paris, France. Eng. Pat. 23,578, December 7, 1893.

BLACK, blue-black, and blackish-green colouring matters for unmordanted cotton are obtained by heating certain aromatic diamines, amido phenols, and other bodies with sulphur and caustic soda. The colouring matters are divided into two series, to the first of which belong those derived from *p*-phenylene diamine, *p*-amido-dimethylaniline, Bernthsen's mercaptan (Annalen, 251, 23), azophenine, and indamines, amido-azo-benzene, and generally azo compounds which, on reduction, give a *p*-diamine. The colouring matters of this series are very soluble in water, but insoluble in acids, and dye yellowish or greenish-black shades. Precipitated by acid, they are only slightly soluble in cold alkalis, but are easily soluble in sodium sulphite, and dye best from this solution, and on exposure to air or treatment with an oxidising agent the colour develops on the fibre. The colouring matters of the second series, which are obtained by the action of sulphur and caustic soda on *o*- or *p*-amido-phenol, oxy-azo-benzene, azoxybenzene, and azo colouring matters which, on reduction, give *o*- or *p*-amido-phenol, are very soluble in water, alkalis, or alkaline sulphites, are insoluble in acids, and, like those of the first series, are best applied from a sodium sulphite solution. For obtaining a colouring matter from *p*-phenylene diamine, a mixture of 1 kilo. of the diamine, 0.5 kilo. of sulphur, and 1 kilo. of caustic soda of 40° B., is heated for 10 hours to 180°–210° C. The bronzy-black mass thus obtained is powdered, and can be used directly for dyeing. By substituting the same weight of *p*-amido-phenol for the *p*-phenylene diamine in the example just given a dark reddish-brown mass is obtained, which, after grinding, can be used for dyeing as described above.—T. A. L.

*Manufacture of Colouring Matters Dyeing Unmordanted Cotton, and their Salts and Sulpho Derivatives.* F. Petersen-Müller, Bâle, Switzerland. Eng. Pat. 8536, April 30, 1894.

VIOLET to blue colouring matters for cotton are produced according to this specification by heating rosaniline with benzidine, telidine, diamido-methylbenzidine, diamido-diphenylalkylether, diamido-hydroxydiphenylalkyl ether, or diamidostilbene, together with benzoic or acetic acid, to 130°–185° C. The rosaniline is substituted to a lower or higher degree according to the proportions of the constituents, the temperature and the length of time the melt is kept on, but in no case is a homogeneous product obtained, although by suitably varying the conditions the product may consist principally of the component desired. Thus, in order to obtain a substituted rosaniline containing three diphenyl rests, 10 kilos. of rosaniline are heated with 100 kilos. of benzidine and 2 kilos. of benzoic acid for two hours to 150°–185° C. The melt is then extracted with dilute hydrochloric acid, and the colouring matter precipitated as hydrochloride by salt. It forms a brown powder, and

dyes unmordanted cotton blue from a slightly acid bath. In place of the benzidine, other diamines may be employed, or a mixture of these with aromatic monamines such as aniline or toluidine, or with diamines such as *o*, *m*, or *p*-phenylene diamine, tolylene diamine, or a triamine such as triaminobenzene. On treatment with sulphuric acid or other sulphonating agents, mono-, di-, and tri-sulphonic acids of the colouring matters can be obtained. —T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

### PATENTS.

*An Improved Paste or Size for Use in the Pasting of Cap Bottoms and the Sizing of Cotton Goods.* W. A. Brown, Manchester. Eng. Pat. 12,345, June 23, 1893.

The patentee employs for above purpose a mixture of starch or farina, pulverised soap, and sugar. These ingredients are taken in the following proportions:—Farina or starch, 16½ ozs.; soap, 1 oz., and sugar, 1 oz.; and dissolved in two gallons of water. After being boiled, the paste is ready for use.—H. S.

*Improvements in or connected with the Producing or Printing of Designs upon Waterproof Fabrics.* J. Frankenburg, Salford, and C. O. Weber, Manchester. Eng. Pat. 12,367, June 23, 1893.

POWDERED alpha-oxy-cellulose is applied to the adhesive rubber surface of waterproof cloth by passing the latter under a gauge, in front of which the dry powder is placed. In this manner an even film is obtained, which, owing to the great affinity of alpha-oxy-cellulose for dyes is printed upon like an ordinary calico. Finally the material is thinly coated with a rubber solution, and the whole vulcanised.

—H. S.

*Improvements in the Manufacture of Flax or other Vegetable Fibre Roofing.* G. McTear, Belfast. Eng. Pat. 14,551, July 28, 1893.

See under IX., page 737.

*Improvements in or relating to the "Retting" of Fibres.* J. C. Pennington and W. O. Allison, New York. Eng. Pat. 22,808, November 28, 1893.

ACCORDING to the patentee the "retting" of flax and other fibrous materials is a partially putrefactive fermentation brought about by the agency of microbes, which destroy the gum and extractive matters. He therefore adds to the retting liquid, tepid water containing pchizomyces microbes and such soft salts and oxides as shall furnish alimentation to the microbes, and promote their growth and multiplication. It is stated that by this treatment flax straw may be retted thoroughly in from 36 to 48 hours.

—H. S.

*A New or Improved Process for Rendering Textile Materials Waterproof and Flame-proof.* H. Rous and G. N. West, London. Eng. Pat. 5718, March 19, 1894.

Two solutions are prepared, one of sugar of lead (½ lb. to 1 gall. of tepid water), and the other of alum (¼ lb. to 1 gall. of tepid water). Both solutions are allowed to stand for 6 hours, and are then mixed together, well stirred, and allowed to stand for 36 hours. As a precipitate results, the liquid is drawn off, and the material to be treated soaked in this liquid for 48 hours. Then the fabric is dried, and afterwards immersed for 36 hours in a solution of tungstate of soda and bromide of potassium (½ lb. of the former and ¼ lb. of the latter to every gallon of water). Finally the material is steamed, dried, submitted to hydraulic pressure, and finished.—H. S.

*An Improved Process for Producing Artificial Whalebone, and Method for forming the same into Strips.* G. Fehrenbach and L. Prud'hon, Paris. Eng. Pat. 6221, March 27, 1894.

HITHERTO the caustic baths employed in the manufacture of artificial whalebone from hair, bristles, or wool have been composed of a mixture of caustic lime and caustic potash. It is proposed to omit the lime, using either caustic potash or caustic soda of a concentration determined by the conditions of temperature and duration of steeping. The hair or other material which has been causticised in this bath is next steeped in very dilute acid, whereupon "the proteinous matter appears and remains adhering to each hair." The material is then washed, the fibres are arranged parallel, and in piles to a given thickness, and submitted to hydraulic pressure whilst hot. The strips thus obtained are laminated, dried, polished, and cut to size.—A. G. B.

## VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

*On the Nature of the Forces which play a part in the Process of Dyeing.* M. A. Rosensiehl. Bull. Soc. Chim. 1894, 11—12, 44—48.

THE author (like others before him) shows, on the basis of well-known facts and simple observations, that the supporters of both the mechanical and chemical theories of dyeing err in their one-sidedness, and he defines the process of dyeing as an operation consisting in covering the textile fibre with a perfectly adherent layer of a coloured substance, this layer being sometimes a compound of a part of the substance of the fibre with a colouring matter.—F. M.

*New Dying Process.* Presented in Competition for a Prize of the Society by M. Bonnet, with report on the same by E. Kopp, E. Noelting, and E. Grandmougin. Bull. Soc. Ind. Mulhouse, 1894, 82—99.

FOUR new processes are described, followed by a report on the correctness and practical utility of the author's observations, the report being based on numerous and detailed experiments carried out by MM. Kopp, Noelting, and Grandmougin.

A. New method of producing manganese brown, and its application in the production of aniline black. The property possessed by tannin of reducing permanganate is made use of. Cotton is boiled in a tannin solution containing at least 60 grms. per litre, or in a decoction of elina galls at 5°—6° B. Allow the cotton to cool in the bath, fix with tartar emetic, and dye in permanganate solution containing not less than 5 grms. per litre. The method may also be applied in printing, the tannin being printed on the goods, which are subsequently passed through permanganate.

Aniline black is produced on cotton dyed as above, by successive treatment with aniline and bichromate according to well-known processes. Blacks may be dyed on mixed silk and cotton goods by making use of the fact that treatment with tannin prevents the formation of manganese brown on silk. By adjusting the amounts of tannin and permanganate used previous to the aniline bath, it is possible to obtain a black on the cotton only, on the silk only, or on both fibres alike.

*Report on above.*—The only novelty in the author's process is the use of tannin: as an almost identical process, in which Cachou de Laval was employed, was in use some years ago. The defects of the process—leaving out of the question the price of tannin and of permanganate—are rapid decomposition of the permanganate bath, difficulty of washing, attacking of wooden vessels, lack of brilliancy and evenness in the aniline black. In printing it is difficult to

produce a discharge on account of the large quantities of tannin used. Clear whites are only obtained by the use of sodium bisulphite, and this injuriously affects the black.

Experiments made with wool show that it behaves almost exactly as silk: however, on chlorinated wool dark shades can be produced with tannin and permanganate.

B. New method of mordanting with lead, and its application for chrome yellow, &c. The mordant used is potassium plumbate, made by boiling lead dioxide with concentrated caustic potash. It is applied by alternately passing the cotton through plumbate solution, and fixing by washing in running water, the operations being repeated several times. For chrome-yellow, mordant in plumbate solution (100 grms. per litre) 15 minutes at 50° C., then pass into bichromate. For brown or black, mordant with plumbate, dye with ammonium sulphide; a black may be thus produced which is fast to soap and weak acids. For mixed silk and cotton fabrics, mordant with plumbate; the cotton only is affected, and on treating with bichromate is dyed yellow, while the silk remains white and can be shaded at will with coal-tar colours. On mordanting with plumbate and passing through permanganate, oxide of lead is fixed on the cotton and oxide of manganese on the silk.

*Report.*—The plumbate may be prepared as follows:—150 grms. caustic potash are dissolved in 125 cc. water, the solution boiled gently, and 130 grms. lead dioxide gradually added. A greyish crystalline deposit of potassium plumbate is formed, which on cooling appears as a solid deliquescent mass, 340 grms. of which are obtained from the quantities given. For use it is dissolved in dilute caustic soda; the resulting solution stands at 31° B., or can be further diluted to 19°, 10°, or 5° B. Its use depends on the fact that on dilution lead dioxide separates out. One minute's immersion in boiling water is a better way of effecting this than the author's method of washing in running water.

The treatment with plumbate is carried out cold, owing to the alkalinity of the liquid: even then the fibre is mercerised if the solution is strong. This mordant has no advantage over other lead compounds for chrome yellow or for sulphide browns and blacks, nor does it show any advantage over permanganate in preparing cotton for aniline black.

A reaction with tannin is worthy of notice and very delicate. 4 cc. of a 0.1 per cent. solution of tannin give a distinct currant-red coloration with plumbate at 31° B. The colour becomes brown on standing.

C. Fixation of lead oxide by alkaline plumbites. Litharge or massicot is dissolved in excess of boiling caustic soda at 26° B., the solution diluted as required, the fibre steeped in the solution and fixed in running water.

*Applications.*—(1.) Mineral colours.—Sulphide browns and blacks, mordant as above, develop in sodium sulphide solution. Chrome yellow: mordant as above, treat with bichromate cold. Metallic oxides: oxides of iron, copper, or manganese are deposited by passing through solutions of salts of the metals.

(2.) Dyewoods.—The black with logwood is worth notice.

(3.) Cachou de Laval and tannin yield very dark shades.

(4.) Artificial colours.—Alizarin gives a violet, naphthol brown a mahogany brown, &c.

(5.) Aniline black.—Mordant with plumbite, chrome, dye with aniline, chrome again. Or mordant with plumbite, pass into manganese chloride, then into permanganate, dye with aniline, chrome. Or pass successively through plumbite, tannin, or cachou de Laval boiling, permanganate, aniline, and bichromate.

(6.) Printing with plumbite.—The plumbite may be discharged with oxalic or nitric acid.

*Report.*—The plumbite is best prepared from lead acetate. To 130 grms. lead acetate dissolved in 2,000 cc. water, are added 1,700 cc. caustic soda at 38° B. heated to 60° C. On adding to this 6,300 grms. water, 10 litres of a solution at 12° B. are obtained. To mordant, pass twice through this solution cold, and after 12 hours wash well with water.

The plumbite is better fixed by cold running water than by immersion in boiling water. It is not readily precipitated on dilution.

**Applications.**—(1.) Mineral colours. — The sulphide colours are fast to soap, but lacking in richness. For chrome yellow use bichromate at 100 grms. per litre. The fixation of metallic oxides offers no point of interest.

(2.) As mordant for dyestuffs. — The shades produced are of little value and fugitive to light. With cochineal a violet appears to be produced, and not a red, as stated by the author. The formation of a violet with alizarin is also doubtful. Basic coal-tar colours can be dyed on cotton prepared with plumbite and tannin, but the method offers no advantage, and the colours are blackened by sulphuretted hydrogen.

(3.) Aniline black. — The plumbite is not practically useful.

**D. Method of obtaining two different shades on mixed fabrics of silk and wool.** Mordant boiling with bichromate; the wool only is mordanted, and acquires the property of oxidising aromatic amines, thus becoming dyed, while the silk remains white, and can be afterwards dyed with suitable coal-tar colours.

**Report.** — In order to apply this process for aniline black, 50 per cent. of bichromate must be used and the mordanting repeated three or four times. Mordant boiling, and dye cold with nitrates of amines, *e.g.*, aniline, ortho- or para-toluidine,  $\alpha$ -naphthylamine, &c. Repeat two or three times. By dyeing cold we obtain the minimum of colour on the silk, but even in this case a good white on the silk does not result. The method can, however, be applied in connection with phenolic colouring matters. Mordant with 3 per cent. bichromate, boiling, dye with anthracene brown, chromotrop, &c. The wool only is dyed. The process is of little practical interest. — R. B. B.

#### *An Application of Silicate of Soda.* G. Geisenheimer. *Comptes rend.* 118 (1894), 192–194.

HOWEVER pure may be the chemicals employed in bleaching linen, one is never sure of getting it perfectly clean, even if the soda crystals are quite white, the soap rich in fatty matters, and the caustic soda free from sulphides and silicates. Often the linen remains reddish, or is covered with large yellow spots, or retains all its original stains. To remove these blemishes the bleacher increases the quantity of caustic or the time of boiling, and even if he succeeds in his endeavours the linen is damaged in the process. These mishaps are usually attributed to the chemicals, whereas they should be attributed to the nature of the water used. Some waters are well spoken of, whereas others are rejected as unsuitable for bleaching. This distinction ought to disappear. The only salts which can usually exercise any effect are those of calcium and magnesium. On boiling, or on addition of soda, calcium bicarbonate forms a precipitate which adheres to the linen; acting as a lake, it fixes in the tissues the yellowish colour of the alkaline solution, and the stains thus produced are not removed by subsequent washings or by oxidising agents. Calcium sulphate acts in a similar way.

When distilled water is used, or water which has been simply purified, these mishaps do not occur; and a chalky water can be rendered harmless by adding to it an alkaline silicate. The silicate must be completely soluble in water, and can be prepared by mixing powdered anhydrous carbonate of soda with 15 or 20 per cent. of a saturated solution of silicate of soda  $\text{NaO}(\text{SiO}_2)_2$ . The salt thus prepared is easily transported and retains its solubility, whereas no silicate obtained directly by fusion is wholly soluble. When added to the lye the silicate produces with the salts of lime and magnesia a flocculent precipitate which settles quickly, is not at all adhesive, and which on boiling becomes as powdery as sand. Experience shows that when the water has been purified in this way very little caustic soda is required. The method here recommended is in accordance with the practice, frequently employed, of using wood-ashes in

bleaching, for when the extract from such ashes is analysed it is found to contain only carbonate and silicate of soda or of potash. — D. E. J.

#### *Discharges and Resists on Silk.* H. Knochlin. *Bull. Soc. Ind. Mulhouse*, 1894, 107–111.

**Fat Resist** consists of resin, pitch, yellow wax, stearin, and rectified petroleum. The fabric, after printing, is dyed in the cold with a coal-tar colour and passed through benzine to dissolve the resin, after which it may be steamed to better fix the colour. For black, mordant the printed pieces with ferric nitrosulphate and dye with logwood. The mordants should always be applied after printing the resist, *e.g.*, a deep blue is obtained as follows:—After printing the resist, work in pyrolignite of iron, pass through chalk water, and dye hot with alizarin blue in alkaline bath, wash, and soap.

**Tin and Zinc Resists and Discharges.** Print with acetate of tin or hydrosulphide of zinc; the resist may be coloured with methylene-blue, phosphine, safranin, &c. Then dye with a "direct cotton" colouring matter. Or dye with the direct cotton colour, *e.g.*, diamine-blue, and print the tin or zinc compound with thickening as a discharge.

**Tartar Emetic Resists under Tannin Colours.**—The resist may contain tartar emetic, gum, oxide of tin, magnesium acetate, zinc sulphate, acetic acid, and a colouring matter if required. After printing this, apply by means of a roller a tannin colour; *e.g.*, for blue use a basic violet and malachite green with tannin, gum, acetic, and tartaric acids; steam and wash. The tannin colours are fixed on silk readily by steaming, but not by dyeing.

**Discharges on Aniline Black.**—Prepare with antimony tannate, pass through aniline ferrocyamide and potassium chlorate, and print acetate of soda and colouring matter, steam for half an hour, treat with weak bichromate, and wash.

**Chromic Acid Discharge on Indigo.**—Applied to silk, this process, which consists in printing on indigo a colour together with bichromate, and passing into oxalic and sulphuric acids, does not give a white, but a light brown; dilute boiling sodium bisulphite serves, however, to destroy this brown colour.

**Resists under Vat Blue.**—Only employed in England. Copper resists are printed on to the silk, which is dyed in the indigo vat and exposed to air to re-oxidise the indigo.

—R. B. B.

#### *The Formation of Resorcinol-green on Cotton, Wool, and Silk.* M. Pokorny. *Bull. Soc. Ind. Mulhouse*, 1894, 116–119.

RESORCINOL-GREEN is usually fixed by dyeing on an iron mordant. It can also be formed in the four following ways:—

I.—Mix together resorcinol and an iron salt, steep the fibre in the solution, and then pass into an acidified solution of sodium nitrite, wash, and dry. Ferric salts are better than ferrous, and the best proportions are 1 molecule of resorcinol to  $\frac{1}{2}$  molecule ferric chloride.

II.—In the above process part of the green colour remains in the nitrite bath, and in this bath mordanted wool can be dyed. A soluble iron salt of dinitrosoresorcinol appears to be formed, somewhat resembling Naphthol-green B (Cassella); the latter, however, contains the  $\text{SO}_2\text{H}$  group.

To prepare the colouring matter take 1 mol. resorcinol,  $\frac{1}{2}$  mol. ferrous sulphate, 2 mols. sodium nitrite, and 2 mols. acetic or hydrochloric acid. A green solution is obtained, and a precipitate which dissolves on prolonged boiling with water. Common salt precipitates the colouring matter from its aqueous solution. This colouring matter dyes mordanted wool and silk, and the bath may be completely exhausted. Copper sulphate completely precipitates the colour from its solution. The dyed wool treated with hot copper sulphate solution acquires a much deeper shade. The resorcinol may be replaced by naphthol, phenol, &c.

111.—A soluble green colouring matter can also be prepared by mixing dinitrosoresorcinol with ferrous or ferric salts under certain conditions. Here also the proportion 1 mol. ferrous sulphate to 1 mol. dinitrosoresorcinol is the best. A precipitate is formed which dissolves on heating with water for some time, the solution having a more bluish shade than 1. or 11. Ferric salts may replace the ferrous. Mordanted wool is readily dyed in the solution.

In all the above methods the iron compounds may be replaced by salts of cobalt, nickel, or copper.

IV.—If dinitrosoresorcinol is heated with solutions of potassium ferro- or ferricyanide a green solution is obtained in which wool can be dyed. The best proportions are  $\frac{1}{2}$  mol. potassium ferricyanide to 2 mols. dinitrosoresorcinol; e.g., 0.4 gram. ferricyanide and 3.5 grams. dinitrosoresorcinol are dissolved in 250 cc. water, and this solution on boiling forms dye-bath.—R. B. B.

#### PATENTS.

*Improvements in, or in connection with, "Hawking" Machines for Indigo Dyeing.* G. and J. Stubley, Wakefield. Eng. Pat. 9938, May 18, 1893.

In addition to the usual "nipping rollers" rotating in the vat, through which the fabric passes, the inventors have added one or more pairs of similar rollers, acting above the vat, and consequently out of the liquor. These rollers are fixed so as to clear the serays, when raised from the liquor. Suitable means are provided for adjusting the pressure between the rollers. It is claimed that there is a great saving of dye material and time by working with this arrangement.—W. P. D.

*Improvements in the Manufacture of Coloured Waterproof Fabrics.* T. Birnbaum, Bow. Eng. Pat. 11,110, June 6, 1893.

THE fabrics are coated in the usual manner with india-rubber, the coating material being tinted or coloured by any suitable method before or after application to the fabric. This coloured ground is then treated with a coating of dyed or tinted farina, the latter being obtained by impregnating farina with a solution of colouring matter with addition of mordants or the like, as required. The process is finished by fixing the farina-coating by any of the well-known vapour or liquor processes, or by a combination of both. Thus a shot effect is obtained by means of the contrast between the coloured ground and the superposed dyed farina.—H. S.

*Improvements in the Bleaching or Cleansing of Vegetable Yarns and Fabrics.* J. Riley and the Thornliebank Company, Limited, Glasgow. Eng. Pat. 11,929, June 17, 1893.

VEGETABLE yarns and fabrics are bleached and cleansed, by the simultaneous action of steam, and alkaline, or other suitable agent. The goods are carried in loops, or festoons, on transverse supports, which are caused to travel through a chamber similar in construction to the ordinary steaming apparatus. The steam fills the chamber, and at a convenient point the cleansing liquor is sprayed down on the goods, so as to thoroughly saturate them. The waste liquor may be collected at the bottom of the chamber and used again.

—W. P. D.

*Improvements relating to the Dyeing of Cotton and other Textile Fibres, and to Apparatus therefor.* H. B. Lake, London. Communicated from Diego Mattei, Genoa, Italy. Eng. Pat. 12,466, June 24, 1893.

THIS invention refers to the dyeing of fibres in the form of sliver, slub, or roving. The arrangement consists of sets of several pairs of rollers, placed above suitable receptacles for collecting the expressed dye liquor. The lower rollers have on their periphery, a rectangular groove to receive the sliver, the bottom of the groove being covered with india-rubber. Before the sliver passes through the rollers it is carried on an endless band, under a special injector, having an interior nozzle of transverse section, changing gradually

from a circular to a rectangular form. The sides of the nozzle are pierced with holes inclined to the longitudinal axis of the nozzle itself. The method of working is as follows:—The fibre to be treated enters the first injector, while the dye liquor passes through the holes in the nozzle under pressure, so as to thoroughly soak the sliver. Then after leaving the first injector it passes through the rollers, the liquor flowing into the first vat, and so on. The sliver, after leaving the last pair of pressing rollers, is dried in the usual manner. By means of suitable pumps, the waste dye liquor can be re-used after the addition of further dye-stuff.—W. P. D.

*Improvements in or relating to Dyeing Apparatus.* J. O. Obermaier, Rheinpfalz, Germany. Eng. Pat. 14,154, July 21, 1893.

THIS refers to improvements in the cop-dyeing machine described in Eng. Pat. 15,000 of 1892. The dye vessel is provided with longitudinal and cross partitions, and the latter are divided into two parts by a central vertical opening, arranged to permit the insertion of a wedge-shaped block. By this means the frames or blocks containing the cops may be wedged very tightly into the dye vessel. Or the cross partitions may be dispensed with, and the frames set closely against one another, to obtain the same effect of tight packing.—R. B. B.

*Improvements in the Means and Method of Preparing Vegetable and Animal Fibres, Fabrics, or Piece Goods for the Reception of Aniline Black.* J. Clapham and W. W. L. Lishman, Bradford, Yorks, and J. Pieard and C. Villedieu, Paris. Eng. Pat. 15,028, August 5, 1893.

THE process of preparation consists of five operations, the goods being steeped successively for a few minutes in each of the following baths:—(1.) Water at 15°–20° C., with a sulphonated or soluble oil, or soap, with or without glycerin, glucose, &c. (2.) Slightly acidulated water. (3.) Water, acid, and a manganate or permanganate, with or without an alkaline chloride, sulphate, nitrate, &c. (4.) Acidulated water. (5.) Water to wash off. The goods are now prepared for the reception of aniline black.

Bath No. 3 may be also used in connection with the dyeing of logwood black on vegetable yarns, and is best applied immediately before the logwood bath.—R. B. B.

*A New or Improved Method of Oxidising Indigo Blues and the like, and Apparatus employed therefor.* J. Grime, Busby, N.B. Eng. Pat. 5870, March 21, 1894.

A MOVABLE endless band made of cotton, metal, or other suitable web is fitted over and driven by two rollers with suitable adjustment for securing correct tension on the band. The goods, after passing through the dye vat and over a draw roller in the usual way, fall in a series of loose folds on to the endless band. This carries the cloth forward at a suitable rate. At the further end of the band, the cloth is again caught up over another draw roller, and then enters the second dye vat, and so on, until the desired shade is obtained.—W. P. D.

*Improved Process for Scouring, Cleansing, Bleaching and Disinfecting Wool and other Fibres or Fibrous Materials.* W. H. and S. F. Hughes, Liverpool. Eng. Pat. 7041, April 9, 1894.

THE material to be treated is first immersed in a hot bath of an infusion of quillain bark in order to dissolve and separate the grease and other adhering matters; then it is transferred into a second bath containing a solution of permanganate or bichromate of potash or soda, and finally passed through an aqueous solution of sulphurous acid, to which a small percentage of oxalic acid is added. The patentee states that this process is more efficient and expeditious than the usual method with alkali and soap.

—H. S.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Thirtieth Annual Report on Alkali, &c. Works, by the Chief Inspector.* Proceedings during the Year 1893, presented to the Local Government Board and to the Secretary for Scotland.

THE passing of the Amending Act in 1892 has considerably increased the work of the inspector under the Alkali, &c. Works Act. The number of works registered in England, Ireland, and Wales up to the close of 1893 was 1,016, showing an increase of 136 on the preceding year. In Scotland there were registered 127 works, concerning which a separate report is made. The number of processes under inspection gives a better indication of the wider scope of the inspectors' work. There are now 1,495 processes of manufacture under inspection, as against 1,225 in 1892, an increase of 270. Adding the 208 processes under inspection in Scotland, the total number in the United Kingdom is 1,703.

Tables are given showing the number of alkali and other works registered in each of the seven districts into which the country is divided for the purposes of inspection, and also of the number of separate processes in each district. From the first of these tables it is seen that there are 101 alkali works registered in 1893, as against 100 in 1892, and 945 other works, as against 810 in 1892. A table is also given showing the average result of all the tests of the acidity of chimney, condenser, and chamber-exit gases made during the year in each district. In all 4,824 visits to works were paid and 4,613 tests made. The tests point out that the condensation and absorption of acid vapours have been maintained at the high degree of efficiency in 1893 that has prevailed during recent years. It has only been found necessary to prosecute two works for contravention of the provisions of the Act. Two works were also prosecuted for non-registration.

**Alkali Works.**—Of the 101 works registered under this head only 58 carry on the old alkali or soda-making process. The remaining 43 are so registered because the work done in them comes within the original definition of an alkali work made use of in the Act, though no soda-making is carried on in them. The ammonia-soda process still continues to gain ground upon the Leblanc process, as shown by the following table:—

SALT DECOMPOSED IN THE LEBLANC AND AMMONIA-SODA PROCESS (INCLUDING SCOTLAND).

	1893.	1892.	1891.
	Tons.	Tons.	Tons.
Leblanc process.....	467,562	519,533	567,983
Ammonia-soda .....	349,609	501,897	278,528
Total.....	817,171	1,021,430	846,511

It is a matter of surprise that the Leblanc process, "which has flourished for more than a century, but seemed now to have received its death-blow, has during the last 18 months shown such renewed vitality that during that time five new Leblanc works have been started, all of which are now in operation."

In 1890, the salt decomposed for alkali-making in the United Kingdom reached the total of 855,029 tons. Since then the total make of alkali has steadily decreased. In 1893, however, there would have been an increase instead of a further decrease had it not been for the scarcity of coal, caused by the long-continued strike of the coal miners during the year.

The new alkali process by Mr. F. Gossage, of Widnes, mentioned in the Chief Inspector's Report for 1892 (this Journal, 1893, 675), has made some progress, but still awaits further development.

A drawing is given of a contrivance which has been devised by Mr. W. L. Renoldson, of Allhusen's works, for

distributing the water in hydrating acid condensers, but which may be of more general application for the condensation of gases. The device consists of a simple means of gauging the quantity of water flowing into the tower at any time. This is done by allowing the water first of all to flow into a small tank, out of which it runs through a number of short nozzles, each of which is fixed at a lower level than the one before it. The quantity of water flowing out of the tank can therefore be gauged by counting the number of nozzles through which it is being discharged. By altering the main supply cock, more or less water can be sent into the tank, and so regulated that the water flows out through more or fewer nozzles. From this small gauge-tank the water flows into a tumbling box below, from which it is thrown alternately on one side or the other of the tower, filling the pipes, which distribute it over every portion.

**Cement Works.**—No radical improvement has been made in the working of cement kilns to prevent the dense white vapour and diminish the foul smell which arises from them, especially in those places where clay, highly charged with organic matter, as in the Southampton district, is used.

An important step is being made at the works of the Oldbury Alkali Company in an endeavour to manufacture cement from the waste carbonate of lime from the Chance-Claus process. The cement already produced stands well all the tests usually applied, and it is to be hoped that longer experience will prove its good quality. This would offer a useful application for a very large quantity of material now entirely waste.

**The Nitric Acid Chlorine Process.**—Last year this process for manufacturing bleaching powder was undertaken in Ayrshire and in Cheshire. In Ayrshire the difficulties met with from the outset prevented the work from being fairly started, and for a time it has been abandoned. In Cheshire the attempt, under another patent, has also not yet been successful.

**Sulphate of Ammonia Works.**—No complaint has been brought during the past year against these works. Although formerly this was one of the most offensive manufactures, it is now "carried on at 368 works in England, &c., and at 59 in Scotland, and yet the public may be said to be quite ignorant of their presence." The following table shows the amount of sulphate of ammonia produced in the United Kingdom, and the sources from which it is obtained. It will be seen that the production is increasing year by year, but there has been a falling off in the quantity made in the iron and carbonising works in consequence of the stoppage of many of these works during the recent coal strike:—

AMOUNT OF SULPHATE OF AMMONIA PRODUCED IN THE UNITED KINGDOM.

	1893.	1892.	1891.
	Tons.	Tons.	Tons.
Gasworks .....	112,179	110,748	107,370
Ironworks .....	8,833	11,000	6,289
Shale works .....	28,485	23,105	26,690
Coke and carbonising works....	3,275	1,071	2,766
Total .....	152,772	144,924	143,115

**The Chance-Claus Process.**—Many improvements have been made since the process was first adopted in 1889, chiefly in details of construction. Owing to great care in the construction of the numerous cocks and pipes which form a part of the apparatus, the complaints of nuisance arising from the escape of sulphuretted hydrogen may be said to have ceased, and no accident arising from its inhalation by workpeople has been reported during the year. In all, about 35,000 tons of sulphur can be produced annually

when the whole of the plant is in operation. Last year the production was 31,350 tons. Most of the tank waste produced on the Tyne, at Oldbury, and at Wednesbury, is treated by this process. In the St. Helen's and Widnes district the plant for treating the whole of the waste made by the United Alkali Co. has been erected, but, as is stated in the report of the district inspector, Dr. Adleck, for some reason or other this company have not yet found it practicable to treat the whole of the waste made. About 200,000 tons of waste were made in their Widnes works, of which 144,000 tons, or 72 per cent., were treated by this process, and yielded 12,835 tons of sulphur and about 1,000 tons of sulphuric acid of 123 Tw. The weak point of the Chance-Claus process is still the imperfect decomposition of the sulphuretted hydrogen. The gases escaping at the final exit contain both sulphurous acid and sulphuretted hydrogen, equivalent to nearly 15 per cent. of the sulphur contained in the waste. These gases are passed through a fire or through heated flues with sufficient air to completely burn the sulphuretted hydrogen before being discharged into the atmosphere.

**Venetian-Red Works.**—In these works red oxide of iron is usually prepared by the roasting of sulphate of iron, whereby a mixture of sulphurous and sulphuric acid is discharged, which has usually been allowed to escape into the air. The number of these works now registered is 15. There is considerable difficulty in dealing with these acids, as no means may be employed that would interfere with the furnace draught. As the production of particular shades of colour is aimed at, no interference with the working of the furnace is permissible. It has been found possible to separate the sulphuric acid by cooling and condensation, and by washing with water; but the sulphurous acid is only sparingly soluble in water and is not condensed on cooling. A method proposed by the chief inspector is now on trial and appears likely to be successful. It is that of leading the mixed hot gases through a tower or chamber filled loosely with light scrap iron down through which water percolates. A solution of sulphate of iron is formed which may be evaporated to the crystallising point by the waste heat of the Venetian-red furnaces, and the crystals recovered can then be used for the further production of Venetian-red.

**Arsenic Works.**—These are of two kinds. Firstly, those in which arsenious acid is made by roasting arsenical pyrites or as a by-product in the roasting of tin and copper ores. Secondly, works in which arsenic acid is made by the oxidation of arsenious acid with nitric acid or a nitrate. Of the former class there are 35 works registered, and these are all situated in Cornwall and the western portion of Devonshire. The difficulty to be overcome in these works is the prevention of the discharge of the arsenic into the atmosphere. The employment of wash towers is only partially successful, as water does not readily take hold of finely-divided dry solid matter suspended in air. By this means also the arsenic is only transferred from the air to the water, which, passing into a neighbouring stream, might do much damage. A dry filter of brushwood, gorse, &c. has therefore been advised and in several cases adopted quite successfully. As brushwood is, however, too quickly destroyed by the acids which accompany the arsenic, some more durable material is sought for. The effect of such filters has been to arrest almost the whole of the arsenic, bringing it below one-tenth of a grain per cubic foot of the chimney smoke on the average.

In the second class of arsenic works there is no danger of the escape of arsenic, but of nitric or nitrous acid. One method of dealing with these nitrous vapours is to lead them into a sulphuric acid chamber, but an objection to this is the intermittent nature of the process. In other cases the fumes are absorbed by strong sulphuric acid in a tower packed with flints, and the nitrated sulphuric acid may be then used in the Glover tower. Another and more common method is to lead the red fumes together with steam and air into columns packed with coke. The acid is thus re-oxidised and is ready for use in a further operation. This method is so nearly perfect that the loss of nitric acid from all causes is less than 5 per cent.

**Hydrochloric Acid Works.**—These works include a number of processes by which hydrochloric acid is produced by other methods than by the decomposition of common salt in the soda manufacture. Prominent among these is a process for the recovery of hydrochloric acid from galvanisers' dippings, devised by Mr. Thomas Turner, of Birmingham. The chloride of iron liquors are allowed to flow gradually upon the hearth of a reverberatory furnace: the chloride of iron is decomposed by the heat, and the hydrochloric acid that is driven off is caught in a wash tower such as is used in alkali works.

**Fibre Separation Works.**—In these works rags consisting of mixtures of cotton and wool are treated with hydrochloric acid gas, which destroys the cotton in the fabric. By cleansing and then mechanically separating the woollen fibres a new white wool is produced, which may be compared not unfavourably with the original wool in appearance. Under the name of "shoddy" this is used in the fabric of new cloth. In the report of the East Lancashire and Yorkshire inspector, Mr. R. Forbes Carpenter, some account is given of the apparatus used in these works. In the first and oldest class of works the rags are suspended in chambers built of brick, tarred inside and out, and heated below by a stove. Hydrochloric acid gas, in proportion to the cotton to be destroyed in the rags, is turned into the closed chamber and the action is allowed to continue through the night; in the morning the chambers are draughted to the condenser by chimney suction, and the fresh air admitted at an opening in the chamber door sweeps the surplus gases before it. In the second class of works the rags are treated in revolving machines of rectangular section placed in a heated stove, the hydrochloric acid gas being introduced at the axis of the machine. Great economies of space, time, and labour are obtained by this method, but it is not suitable for every description of rags, and the old method finds more favour where the least amount of "tendering" and loss of colour are essential. Another step in advance has been to make the operation a continuous one, but this can only be carried out where the rags are uniform in quality. Another process that has recently been proposed, which is being tried experimentally, is the first departure from the usual lines to meet the question of nuisance from the escape of gaseous HCl, and at the same time bring it into use without absorption by a condenser. The surplus gases from the machine, together with the fuel gases from the stove, fired for this purpose with coke, are drawn by a fan through a second machine filled with fresh moist rags to be dried and subsequently carbonised. The second machine acts as a dry condenser; the HCl is kept gaseous by the hot stove gases, and performs its function by partly carbonising the rags in the machine. The completion of the carbonisation is afterwards much more rapid, and a saving of 20 per cent. of acid is claimed. Manufacturers have all of them been informed of the duties laid upon them by the Alkali Acts, and a few have responded promptly and willingly, but the inspector has met with a great deal of opposition and passive resistance from the majority of those engaged in this industry, arising from their profound ignorance of even elementary chemical facts.

**Tar Works.**—The inclusion of these works under the Alkali Act has added most to the work of the inspectors. 118 of these works have already been registered. In preventing nuisance during the distillation of tar the escape of noxious vapours from the ends of the still worms and from the pitch bays has been found to be the chief difficulties to overcome. The gases from the ends of the still worms contain sulphuretted hydrogen, particularly at the beginning and end of tar-distillation, and also a considerable amount of light hydrocarbon vapour which does not condense at the usual temperature of the worms. In some works the gases are passed through a bed of oxide of iron or slaked lime. In other works they are burned in a furnace fire, various methods being adopted to prevent firing back, such as reducing the diameter of the pipe as it approaches the fire, the introduction of a water seal between the still worm and the furnace, or the production of a strong draught by means of a steam jet or a fan. In the report of Mr. Ballard, the inspector for Cheshire, North Wales, and part of

Lancashire, the firing back was found to be quite prevented by the inrush and cooling effect of the air on the end of the pipe by allowing it to enter the fire with an open space all round it instead of building it in. Details of various methods of dealing with these gases are described in the reports of the inspectors. In many cases, owing to the differences in the character of the tar to be distilled, the means to prevent nuisance applicable in some cases cannot be used in others. Thus, in the case of a tar distilled in the eastern counties a carbonaceous deposit has frequently been found to form in the still; this from time to time separates suddenly from the bottom of the still, and exposes an over-heated surface which causes a violent disengagement of vapour. These eruptions would be dangerous were any obstruction offered such as would be caused by a bent pipe or closed box at the end of the still worm. The most serviceable arrangement there is the plain worm end fitted with a loose cap from which a pipe rises to lead off the noxious gases.

The second source of nuisance which has called for attention are the vapours given off during the running of the pitch. The usual custom in tar works now is to distil the tar until "hard" pitch is obtained. It is then mixed with a proportion of creosote oils or waste anthracene oils so as to make it into "medium soft" or "soft" pitch, as required. It is then run from the still into a cooling vessel, and thence it is run into the pitch bay. It would be very desirable that all pitch bays be covered in, but in some cases this is not practicable because of a deposition of a highly carbonaceous hydrocarbon which ignites on exposure to air. It is deposited under protection of a dense cloud of tar-vapour, but when this is blown away by a slight gust of wind the carbon has become ignited and has transmitted the fire to the mixture of tar-vapour and air, thus causing explosion with burst of flame. Much interesting information with regard to tar works will be found in the report of Mr. F. Napier Sutton, the inspector for the south-eastern counties. An account will also there be found of a continuous tar still, the invention of Mr. F. Lennard, of the firm of Forbes, Abbot, and Lennard. This still is capable of treating from 15,000 to 20,000 gallons of tar per 24 hours, and has been at work successfully for the past 12 months, during which time about 4,000,000 gallons of tar have been passed through it. The chief inspector has tabulated the information so far collected with regard to the number and capacity of stills used in different works, the type of pitch-cooler used, the temperature at which pitch is run, the means used for destroying still-gases, &c. These tables occupy six pages of the report.

**Felt Works.**—In these works tar is heated in large open pots and conveyed to a small tank through which an endless sheet of felt passes; on leaving the tank the felt then travels between heated rollers. This operation is carried on in a closed workroom, in which many women and lads are employed, and the atmosphere of the place is charged with tar-vapour to an extent which must be highly injurious to the operatives. It has not been found easy to confine this vapour, as there must be free access for the workmen to the tar tank and machine, but it is hoped that a satisfactory plan may soon be arrived at.

**Zinc Works.**—The complaints brought against these works for nuisance are due to the sulphurous acid driven off in roasting blende, and to vapours of oxide of zinc which escape at the nozzles of the retorts in which the zinc is smelted. As in many other metallurgic processes whereby sulphurous acid is evolved from furnaces, no effectual means of arresting it is known. The difficulty of dealing with the vapours of oxide of zinc is increased by the fact that they rise from numerous small sources and are not enclosed in a furnace or flue. An attempt has been made to collect them by draughting them away through a projecting hood of sheet iron, but these hoods reflected too much heat on the heads of the men, or if removed further they failed to collect the fumes. A partial success has been obtained by enclosing the nozzle ends behind loose iron plates, which can be removed when necessary for the working. From above this enclosure the fume is draughted away to the flues, where the greater part of it is deposited.

For treating dust-laden air of this character the chief inspector suggests the use of a dry filter of such materials as are best suited to the occasion. In the case of fumes of zinc, lead, copper, &c., light waste scrap iron, such as thin sheet clippings, waste wire &c., might be useful. A hood of 5 or 6 ft. in thickness and of considerable superficial area might be supported on iron bars placed in a brick chamber. The smoke, admitted into the cavity below, would rise up through the filtering material and thence to the chimney, and if suitable holes were left in the sides of this chamber, iron bars might from time to time be inserted so as to shake up the filtering medium and cause the lead or zinc oxide to fall into the cavity below, thus keeping the filter clear.

**Alkali, &c. Works in Scotland.**—The Amending Act of 1892 has released 11 small saltworks from the obligation to register, and three new works, viz., one Venetian-red work, one muriatic acid work, one nitrate of iron work, have been registered. There is an increase of 30 in the number of processes under inspection. The total number of works registered is 127, and the number of processes is 208. The details of the inspection of these are given in the report of Mr. W. S. Curphey, the inspector. With one unimportant exception the infractions of the Act, reported during the year, were such as occurred from temporary unavoidable causes.

A general index of the first 30 reports under the Alkali, &c. Works Regulation Act is appended to this year's report.—H. S. P.

*The Concentration of the Mother-Liquors obtained in the Manufacture of Alum.* J. Wiernik. *Zeits. angew. Chem.* 1894, [10], 289—290.

THE concentration of the mother-liquors forms an important phase in the manufacture of alum. In the first place, the excess of sulphuric acid (which acid is employed for the decomposition of the aluminous minerals—bauxite, alunite, kaolin, &c.) remains in the mother-liquors, and can, by concentrating the latter, be recovered and turned into account. Secondly, the washings of the decomposed mineral residues, as well as the washings of the crude alum, consist of more or less dilute solutions of alum (generally very dilute), and to recover the alum it is necessary to concentrate them to the point of crystallisation.

The mother-liquors and washings are mixed in a wooden cistern lined with lead, and evaporated with steam to a density of 40° Beaumé. The lyes thus concentrated are, before cooling, mixed with an additional quantity of sulphuric acid (account being taken, of course, of the amount of sulphuric acid which they already contain) and employed for the decomposition of a fresh amount of aluminous mineral.

By means of this *modus operandi* nothing, so to speak, is lost from the mother-liquors. When, however, ferriferous minerals (bauxite, alunite, and the like) are made use of, the iron accumulates in the mother-liquors, until at last these contain so much iron that they not only render a fresh quantity of alum highly impure, but hinder its crystallisation. Such ferriferous mother-liquors form a troublesome by-product which is not easily disposed of; they cannot be run into the sewer on account of the not inconsiderable amount of acid which they contain.

It might be supposed that such ferriferous lyes could be utilised as a source of iron sulphate; this is, however, impossible, since, when they are evaporated, nothing but a muddy mass is obtained, which cannot be separated from adhering mother-liquor.

By the following process it is possible to free the mother-liquors from the greater portion of the iron which they contain:—The concentration of the lyes is taken to 50° Beaumé instead of 40° Beaumé, and after turning off the current of steam, a precipitate of iron salt forms, which varies in composition according to circumstances. This precipitate quickly settles; the supernatant liquor contains considerably less iron and can be used again for crystallising purposes. The

decrease in the amount of iron with increasing concentration is shown in the following tabulated analyses :—

	Fe Grms. per Litre.
Mother liquor of 90° Beaumé .....	16.80
Same mother-liquor evaporated to 12° B. and diluted to 30° B. ....	13.20
Same mother-liquor evaporated to 15° B. and diluted to 30° B. ....	11.56
Same mother-liquor evaporated to 17° B. and diluted to 30° B. ....	8.80
Same mother-liquor evaporated to 19° B. and diluted to 30° B. ....	8.04

The composition of the precipitates above mentioned varies according as the iron exists in the mother-liquor in the ferrous or ferric condition. By evaporating completely oxidised (ferric) lyes, the precipitate is yellowish-white, crystalline, and insoluble in water. It forms hard incrustations on the steam worm and the concentrating cistern, which are very difficult to remove. A point of supreme importance, however, is that the formation of this precipitate is attended with a loss of alumina and potash (also of ammonia when "mixed alums" are manufactured). A specimen of this precipitate was withdrawn, and, after washing and drying, submitted to analysis. From the mean values of two analyses it appeared to be a basic ammonium potassium aluminium sulphate of the formula  $2\text{Fe}_2\text{O}_3 \cdot 5\text{SO}_3 \cdot \text{Al}_2(\text{SO}_4)_3 \cdot \text{K}_2\text{SO}_4 \cdot (\text{NH}_4)_2\text{SO}_4$ . The salt is not only insoluble in water, but also in acids, and is decomposed with the evolution of ammonia and separation of ferric oxide and alumina when treated with alkalis in the cold. It follows from these observations that the constituents of this salt can no longer be turned to account in the manufacture, and therefore the formation of the salt must, if possible, be avoided. With this object in view, it is advisable to keep the major portion of the iron present in the mother-liquors as ferrous salt; this is accomplished by reducing the lyes (the reduction need not be complete) in the evaporating tank. After numerous experiments, the author finds that thin chips of green poplar wood form the best and cheapest

of reducing agents. The chips are packed into a high leaden sieve, which is then lowered into the concentrating tank. Under the influence of the hot acid lyes the chips are dissolved without carbonisation (apparently forming in the first stage, oxalic acid, which then decomposes into carbonic oxide and carbon dioxide), with the simultaneous reduction of the ferric oxide to ferrous oxide. When, under these circumstances the lyes are evaporated to a density of 50° Beaumé, most of the iron separates on the bottom of the tank as a black, muddy, amorphous precipitate, also in other parts of the apparatus (on the steam worm, for example) in small black crystals; the mass is readily soluble in water. Analysis of a portion of the dried substance points to the formula  $3\text{FeSO}_4 \cdot 2\text{Fe}_2(\text{SO}_4)_3$ , thus :—

	Found.	Calculated.
	Per Cent.	Per Cent.
FeO .....	16.98	17.29
$\text{Fe}_2\text{O}_3$ .....	25.76	25.48
$\text{SO}_3$ .....	57.68	57.32

The removal of this precipitate from the evaporating tank after running off the concentrated lyes is, on account of its nature, quite easy.—A. R. L.

#### *Reactions of Acid Potassium Arsenite with Metallic Salts.* C. Reichard. Ber. 1894, 27, 1019—1036.

THE author has filled up several gaps in the known series of metallic arsenites. The salts were prepared by the interaction of acid potassium arsenite with the metallic sulphate, chloride, or nitrate; in many cases some of the acid of the salt was liberated.

The following list of arsenites epitomises the author's work :—

Composition.	Prepared from	Acid liberated.	Description.	Originally prepared by
$\text{H}_2\text{O} \cdot \text{As}_2\text{O}_3$ .....	$\text{HgNO}_3$ .....	.. ..	Yellowish, decomposed by light.	Berzelius
$2\text{CuO} \cdot \text{As}_2\text{O}_3$ .....	$\text{CuSO}_4$ .....	Sulphuric acid	Green powder	Bloxam
$2\text{CdO} \cdot \text{As}_2\text{O}_3$ .....	$\text{CdSO}_4$ .....	Sulphuric acid	White amorphous powder	..
$2\text{HgO} \cdot \text{As}_2\text{O}_3$ .....	$\text{HgCl}_2$ .....	Hydrochloric acid	Yellowish-white, decomposed by light.	Berzelius
$2\text{PbO} \cdot \text{As}_2\text{O}_3$ .....	$\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ .....	Acetic acid	White	Filhol
$3\text{Au}_2\text{O} \cdot \text{As}_2\text{O}_3$ .....	$\text{AuCl}_3$ .....	Hydrochloric acid	Purple-red powder, blackened by warming.	..
$3\text{Ag}_2\text{O} \cdot \text{As}_2\text{O}_3$ .....	$\text{AgNO}_3$ .....	Nitric acid	Yellow microscopical needles, decomposed by light.	Filhol, Bloxam, Pasteur, &c.
$3\text{PbO} \cdot \text{As}_2\text{O}_3$ .....	$2\text{PbO} \cdot \text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ .....	.. ..	White	Streng
$3\text{MgO} \cdot \text{As}_2\text{O}_3$ .....	$\text{MgSO}_4$ .....	Sulphuric acid	White powder	Stein
$3\text{ZnO} \cdot \text{As}_2\text{O}_3$ .....	$\text{ZnSO}_4$ .....	Sulphuric acid	White crystals	Bloxam
$5\text{SnO}_2 \cdot 2\text{As}_2\text{O}_3$ .....	$\text{SnCl}_4$ .....	Hydrochloric acid	Yellowish-white	Berzelius
$5\text{TiO}_2 \cdot 2\text{As}_2\text{O}_3$ .....	$\text{TiO}_2 \cdot \text{SO}_3$ .....	Sulphuric acid	White crystals	..
$\text{PtO}_2 \cdot \text{As}_2\text{O}_3$ .....	$\text{PtCl}_4$ .....	Hydrochloric acid	Bright yellow	Simon
$\text{PdO}_2 \cdot \text{As}_2\text{O}_3$ .....	$\text{PdCl}_4$ .....	Hydrochloric acid	Bright yellow	..
$\text{UO}_2 \cdot \text{As}_2\text{O}_3$ .....	$\text{UO}_2(\text{NO}_3)_2$ .....	.. ..	Bright yellow	..
$\text{Fe}_2\text{O}_3 \cdot \text{As}_2\text{O}_3$ .....	$\text{FeCl}_3$ .....	Hydrochloric acid	Rusty yellow powder	..
$\text{Al}_2\text{O}_3 \cdot \text{As}_2\text{O}_3$ .....	$\text{Al}_2(\text{SO}_4)_3$ .....	Sulphuric acid	White	Thorey
$\text{Cr}_2\text{O}_3 \cdot \text{As}_2\text{O}_3$ .....	$\text{Cr}_2(\text{SO}_4)_3$ .....	Sulphuric acid	Dark green, soluble in KOH.	..
$\text{FeO} \cdot \text{As}_2\text{O}_3$ .....	$\text{FeSO}_4$ .....	.. ..	Greenish-white, becomes brown in air.	..
$\text{BaO} \cdot \text{As}_2\text{O}_3$ .....	$\text{Ba}(\text{NO}_3)_2$ .....	.. ..	White, soluble in much water.	..
$3\text{CoO} \cdot 2\text{As}_2\text{O}_3$ .....	$\text{Co}(\text{NO}_3)_2$ .....	Nitric acid	Amethyst-coloured powder.	Girard
$3\text{NiO} \cdot 2\text{As}_2\text{O}_3$ .....	$\text{Ni}(\text{NO}_3)_2$ .....	Nitric acid	Bright green.	Girard

Composition.	Prepared from	Acid liberated.	Description.	Originally prepared by
$3\text{CaO} \cdot 2\text{As}_2\text{O}_3$ .....	$\text{CaCl}_2$ .....	Hydrochloric acid	White powder, soluble in much water	"
$3\text{SrO} \cdot 2\text{As}_2\text{O}_3$ .....	$\text{Sr}(\text{NO}_3)_2$ .....	Nitric acid	White powder, soluble in much water.	"
$3\text{MnO} \cdot 2\text{As}_2\text{O}_3$ .....	$\text{MnCl}_2$ .....	Hydrochloric acid	White, becoming red to brown in air.	Strom
$3\text{SnO} \cdot 2\text{As}_2\text{O}_3$ .....	$\text{SnCl}_2$ .....	Hydrochloric acid	Yellowish white, decomposed by acids and alkalis with separation of arsenic.	Berzelius

**Leadon Pipes in Vitriol Manufacture.** A. Lambert.  
Bull. Soc. Chim. 11, 1894, 343—351.

WHEN considerable lengths of piping are requisite for the conveyance of vitriol from one part of a factory to another, it is convenient to know what dimensions will suffice to obtain a sufficiently rapid flow without entailing the locking up of capital in leaden installations more solid and of greater magnitude than is necessary. The formulae applicable in the case of water cannot be employed in such

cases; the practical formula  $V^2 = \frac{2gh}{1+R}$  may, however, be used, where  $V$  is the velocity of the fluid,  $h$  the "head" or elevation from which it flows, and  $R$  a coefficient referring to the resistance to passage of the fluid, and composed of four parts, viz.,  $Z_1$ , applying to the resistance at the entrance of the fluid into the pipe;  $Z_2$ , to sharp angles in the pipe;  $Z_3$ , to less abrupt changes of direction; and  $Z_4$ , the resistance due to friction; so that  $R = Z_1 + Z_2 + Z_3 + Z_4$ . The value of  $Z_1$  was determined for acid at 60° B. by noting the time requisite to run the acid down through a certain difference of level in a large reservoir, using orifices respectively of 35, 40, 45, and 50 millimetres in diameter; figures varying between 0.67 and 0.70 were obtained, giving an average 0.686, or more than 10 times the value corresponding with the flow of water under the same conditions. As regards  $Z_2$ , pipes bent to sharp angles (elbows) of 60° and 90° gave respectively the average values 0.925 and 2.525, whereas where water is in question, the resistance is given by a formula of the character—

$$Z_2 = A \sin^2 \frac{\delta}{2} + B \sin^4 \frac{\delta}{2}$$

Applying this formula to sulphuric acid the equation becomes—

$$Z_2 = 2.366 \sin^2 \frac{\delta}{2} + 5.224 \sin^4 \frac{\delta}{2}$$

For curved pipes with radius of curvature 15 cm., and interior diameters 35, 40, and 45 mm. respectively, the corresponding values of  $Z_3$  were 0.814, 0.797, and 0.798. The resistance due to friction when a fluid passes along a pipe is proportionate to the diameter, so that  $Z_4$  may be put  $= \lambda \frac{1}{d}$ , whilst  $\lambda = \frac{V}{0.042001}$ , where  $V$  is the velocity.

Putting together these various valuations, tables may be calculated for various cases, based on the general formula—

$$h = (1 + Z_1 + Z_2 + \dots + \lambda \frac{1}{d}) \frac{V^2}{2g}$$

—C. R. A. W.

**Specific Gravity of Calcium Chloride Solution.** S. U. Pickering. Ber. 27, 1372—1385.

IN the course of an experimental examination of the physical properties of calcium chloride solution, the following figures were obtained (*inter alia*) as regards the

relationships between the strength, the freezing point, and the density

Specific Gravity at 17.925° C.	Percent- age of $\text{CaCl}_2$	Freezing Point.	Specific Gravity at 17.925° C.	Percent- age of $\text{CaCl}_2$	Freezing Point.

**Spontaneous Formation of Pyruvic Acid from an Aqueous Solution of Tartaric Acid.** R. Otto. Ber. 27, 838.

AN approximately 25 per cent. solution of tartaric acid contained in a stoppered flask of colourless glass was exposed to light at a western window for a year. The solution at the end of this time was of a dark yellow colour, smelt strongly of caramel, and was formed by the phenylhydrazine reaction to contain pyruvic acid.—A. R. L.

**Spontaneous Formation of Pyruvic Acid from an Aqueous Solution of Tartaric Acid.** R. Otto. Ber. 27, 1264—1265.

AN examination of the dark-coloured solution containing pyruvic acid (last abstract) has shown that it is quite free from micro-organisms, so that the observed conversion of tartaric acid into pyruvic acid cannot, as was at first supposed, be due to the agency of such organisms.

—A. R. L.

**Formation of Aluminium Sulphide.** F. Gruy. Zeits. angew. Chem. 1894 [10], 299.

See under XI., page 742.

*Effect of Heat on Iodates and Bromates.* E. H. Cook.  
Proc. Chem. Soc. 1894 [139], 119—129.

POTASSIUM iodate is difficult to purify; repeated crystallisations from water fail to give a reliable product. The method adopted was, therefore, to crystallise from water once or twice, then to precipitate the solution by means of alcohol, collect the precipitate and recrystallise from water. The first effect of heat on the iodate is to cause the substance to become brown. This brown substance has the same composition as the original iodate, and it is formed without any alteration taking place in weight. When the heating of the iodate is continued up to the time of its ceasing to lose weight, the following changes are observed: the brown substance fuses and becomes a colourless liquid; during the fusion, iodine is evolved; after continued and regulated heating, the liquid becomes a white solid, and when thoroughly solid, ceases to lose weight; the residue is potassium iodide.

The experiments having failed to produce any oxy-compounds, it was thought that these compounds might be formed if the heating were effected under reduced pressure; but at a pressure of 70 mm. the results were precisely the same as under normal conditions.

Finally, in order to discover at what stage the chlorine known to be evolved when chlorate is heated is produced, experiments were made with that substance. It was found that the chlorine was evolved just at the same period as the iodine from the iodate, viz., during the melting of the salt. The amount formed is 0.03 per cent.

It would therefore appear that the halogen is liberated early, but that it is not actually set free until the structure of the salt is broken down—in the case of the iodate by fusion, and in that of the bromate by decrepitation (at about 180° C.).

#### PATENTS.

*Improved Still and Apparatus for the Distillation of Ammoniacal Liquor and other Fluids.* G. Pettigrew, Middlesbrough. Eng. Pat. 10,171, May 23, 1893.

ABOUT a third of the upper part of a vertical still is fitted with shallow trays, "helical in form," communicating each with that next below, by an overflow pipe into a walled receptacle, forming a water joint, so that the liquor continuously overflows on to that tray. The ammoniacal liquor is run continuously into a centrally-placed pipe at the top of the still, into the centre circumference of the first tray, from which it flows spirally outwards, and is discharged into the tray beneath, in the manner described, near the circumference, whence it flows spirally towards the centre, to descend by an overflow pipe to the centre of the next tray, and so through the series. The fluid is taken from the last tray nearly to the bottom of a compartment below, whence it passes by a siphon into a lower compartment to meet milk of lime entering in "specified quantity" by a siphon arrangement. Steam is admitted to the bottom of the still in the usual manner, and, with accompanying gases, passes upwards through hooded short pipes placed about equidistant along the circumvolutions of each tray. The bottom edges of the hoods are serrated, so as to be always covered with liquor when the still is in action, the exit of the vapour and gases being through such serrations into the liquor. The gases are led to the saturator through a suitable outlet pipe in the hood. The spent liquor is run off intermittently.—E. S.

*Improvements in Evaporating Saline Solutions.* Sir L. Bell, Middlesbrough. Eng. Pat. 13,709, "June" 14, 1893.

A STEAM boiler furnace is provided with duplicate flues, for alternate use. When one set of flues has become highly heated the products of combustion are caused to enter the other set, and the spent steam from the engine is passed through the heated flues set at liberty, from which the

steam, now superheated, is admitted beneath the salt or brine pan, and allowed exit as moist steam from the far end of the pan. Or a series of pans may be similarly heated.—E. S.

*Improvements in the Production of Nitric Acid, Caustic Alkali, and Ferric Oxide.* G. Lunge, Zürich, Switzerland, and F. Maxwell-Lyte, London. Eng. Pat. 13,654, July 13, 1893.

PURPLE ore, or other form of ferric oxide, finely powdered, is mixed with sodium nitrate in such proportion that the mass may remain porous when heated to the temperature required to effect decomposition. The proportion preferred is two parts ferric oxide to one part of sodium nitrate, for which potassium nitrate may, if desired, be substituted. The mixture is heated in a current of mixed air and steam to an incipient red heat, say between 450° and 550° C., though the effective range is somewhat wider. The air and steam is preferably heated to the same temperature as that of the mass. The nitrous fumes evolved are collected and recovered as nitric acid by the use of air and water. The residue is a dirty green mass, consisting essentially of sodium (or potassium) ferrite, which, on treatment with water, yields caustic alkali and ferric oxide. The ferric oxide is levigated to separate any coarse particles of unattacked ore, and is then fit for use as a paint or polishing substance. The differences between this process and that patented by A. Vogt, Eng. Pat. 22,018 of 1891 (this Journal, 1893, 43), are pointed out.—E. S.

*Improvements in the Production of Caustic Alkali and Chloride of Lead for Conversion into Chlorine and Refined Lead.* F. Maxwell-Lyte, London, and G. Lunge, Zürich, Switzerland. Eng. Pat. 13,655, July 13, 1893.

THE present invention is an improvement upon Eng. Pat. 8692 of 1891 (this Journal, 1892, 686), according to which lead nitrate (obtained by dissolving lead oxide in nitric acid) is decomposed by an alkali chloride, such as sodium chloride, to form sodium nitrate and lead chloride. On then heating the sodium nitrate with ferric oxide, sodium ferrite is formed, with evolution of nitrous fumes, which are collected and recovered as nitric acid. About equal quantities were taken of the alkali nitrate and ferric oxide, and at the high temperature required to effect the decomposition, the material fluxed, and the nitrogen oxides evolved were so far split up as to be irrecoverable as nitric acid.

To overcome the defect in the former process, the proportion of ferric oxide is so far increased as to form a porous mass with the nitrate when heated. When ferric oxide, in the form of "purple ore," is used, two parts are taken to one part of the nitrate or thereabouts, and the heated mixture is subjected to the action of a previously similarly heated mixture of air and steam. The quantity of steam is carefully regulated, and the air is kept in due excess for converting the lower nitrogen oxides into nitric acid by means of a "Lunge tower," or otherwise. The resulting ferrite is decomposed by water to obtain caustic alkali and ferric oxide.

The liquor filtered off from the lead chloride obtained on mixing solutions of an alkali chloride and lead nitrate, still contains dissolved lead chloride. As much as possible of this is recovered by concentration and crystallisation, and the lead remaining in solution is precipitated by an alkali or alkaline earth.—E. S.

*An Improved Process for Producing Basic Lead Salts and Obtaining certain By-Products.* G. Lunge, Zürich, Switzerland, and C. H. Maxwell-Lyte, London. Eng. Pat. 13,656, July 13, 1893.

CRUDE pig lead is oxidised to form litharge, which is dissolved in nitric acid, and finely-divided lead is added to precipitate silver and other foreign metals. The silver lead obtained is a by-product of the process, when crude lead is first operated on. Litharge obtained from refined lead may,

\* Probably a misprint for July 14.

however, be used, though with less advantage. Basic lead carbonate is precipitated from the lead nitrate solution by adding sodium hydroxide and carbonate in the proper proportions, which are approximately 33 per cent. and 67 per cent. respectively. The sodium nitrate solution separated from the precipitate is, while being dried up, stirred with so much ferric oxide as will prevent fluxing of the mixture when this is subsequently heated with air and steam to recover nitric acid, caustic alkali, and ferric oxide, in the manner already described in the abstract of the immediately preceding patent.

The reactions taking place are represented by the following equations:—

The operations are similar when any other basic lead salt is required. For instance, basic lead chloride and caustic soda are produced by using brine instead of sodium carbonate. A chloro-carbonate may be obtained by using a mixture of sodium carbonate and chloride. "Sulphate, oxalate, or any other salt of soda may be employed so long as on addition to the lead nitrate it produces a sufficiently insoluble basic salt of lead and a residual nitrate from which the nitric acid is capable of being recovered in the manner specified, for use over again."—E. S.

#### *Improvements in the Treatment of Bicarbonate of Soda.* Sir L. Bell, Middlesbrough. Eng. Pat. 13,708, July 11, 1893.

SUPERHEATED steam is passed over moist sodium bicarbonate contained in a close chamber. Dry sodium carbonate then remains, while the mixed gas and vapour are collected in a cooler, where water is deposited, and nearly pure carbonic acid recovered, suitable for use in the soda process.—E. S.

#### *A Process for Utilising Acid Sulphates of Soda.* R. E. Chatfield, Sewardstone, Essex. Eng. Pat. 19,530, October 17, 1893.

RESIDUES obtained of acid sodium sulphates in the manufacture of nitric acid, as in the process described in Eng. Pat. 16,512 of 1893, or resulting from other processes, are saturated in aqueous solution with ammoniacal compounds or vapours from gas-liquor or other sources. If the residues consist of normal sodium bisulphate, the neutralised and filtered solution may be treated by either of two processes, (A) or (B). According to process (A), the solution, 48 per cent. of the salts in which are ammonium sulphate, is concentrated up to 76° Tw., and the sodium sulphate which falls during the concentration is fished out, to be afterwards dissolved in water and crystallised. The liquor will then contain salts enriched in ammonium sulphate to about 65 per cent. Process (B). The solution of salts containing 48 per cent. ammonium sulphate is brought to a specific gravity of 55°—60° Tw. at 90° F., or to corresponding density for other temperatures, and allowed to cool. The hydrated sodium sulphate (Glauber's salts) then crystallises out, and, after draining off the mother-liquor, is covered with water. These washings, when run off, are used for soaking subsequent lots. The salts in the well-cooled mother-liquor may contain as much as 77 per cent. ammonium sulphate.

Liquors having salts in solution containing 65 per cent. and upwards ammonium sulphate, as is the case with the mother-liquors obtained by either of the described processes, are evaporated, and the mixed sulphates fished out are agitated or ground with sodium sulphate washings, cold mother-liquors or water, until the density of the liquor ceases to rise, even though more salts are added. Such

density will be about 57° Tw., and the salts present will contain about 88 per cent. ammonium sulphate to 12 per cent. sodium sulphate, or a proportion of 8 equivalents of the former to 1 equivalent of the latter. From this liquor ammonium sulphate can be fished out on concentration up to a density of 76° Tw., when as much as possible of the liquor is run off before re-charging with fresh liquor of 88 per cent. ammonium sulphate. The liquor run off can be brought round up to the circle again. The processes are obviously applicable to sodium sulphates containing any excess of sulphuric acid.—E. S.

#### *Improvements in the Manufacture of Caustic Soda and Potash, out of Nitric and Sulphuric Acids.* W. Garraway, Netherfield, Lancashire, N.B. Eng. Pat. 7412, April 14, 1894.

SODIUM nitrate, preferably dried, is mixed with about two and a half times its weight of burnt lime, and is heated in a cast-iron retort into which superheated steam is passed and a little hot air when required. Nitric acid is evolved, and may be conducted to a vitriol chamber or Glover's tower, or may be condensed directly. The mixture of caustic soda and lime left in the retort is lixiviated, with aid of steam if necessary, and the solution filtered or decanted off; the lime is boiled down to produce caustic soda. The lime residue is dried and heated to redness to fit it for re-use. Potassium nitrate may be similarly treated to obtain caustic potash and nitric acid. Magnesia, baryta, or strontia may be substituted for lime in the process. The apparatus shown in the drawings for carrying out the invention consists of a pair of horizontal iron retorts, with drawing-off and charging doors, set over pyrites burners, and heated by the flame of the burning pyrites. The superheated steam-supply pipes and pipes leading the nitric acid to a Glover's tower are also shown. This pair of retorts is adapted for use in combination with a set of six chambers, so that one retort may be discharged while the other is still working. If not intended for use in connection with the manufacture of vitriol, the retorts may be heated from ordinary fuel in any suitable furnace.—E. S.

## VIII.—GLASS, POTTERY, AND ENAMELS.

### PATENTS.

#### *Improvements in the Manufacture and Production of Stoneware Sanitary Pipes and the like.* H. Tagby, Ashby-de-la-Zouch. Eng. Pat. 11,098, June 6, 1893.

THE object of the patent is to prepare stoneware pipes in such a manner that the joints between successive lengths of pipe may be more secure and impervious than is usually the case. To this end both the spigot and socket end of each length of pipe are protected by rings of dry sand or clay, so that the glaze applied to the pipe may be prevented from adhering to the spigot and socket. The surface being thus kept rough and unglazed, affords a good hold for the cement used in jointing the pipes. Additional security of joint may be obtained by the use of longitudinal or circumferential grooves on the spigot and socket, or by the use of a double joint arranged so that the included annular space may be filled up with cement.—B. B.

#### *New or Improved Substitute for Pounce-stone, and Process of Manufacturing the same.* H. Salmon and J. E. Whiting, Leeds. Eng. Pat. 13,386, July 10, 1893.

ONE hundredweight of "crushed meanwood sandstone" is mixed with 7 lb. of bay-salt, ground and sifted, freed from any particles of iron that may be present by passage

through a magnetic separator, mixed with 1 peck of soft-wood sawdust, previously wetted, the whole mass moulded and fired. The product consists of siliceous grains held together to form a porous pumice-like mass. Substances equivalent to those mentioned above may be substituted.

—B. B.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Slag Cement Experiments.* R. W. Mahon. J. Franklin Inst. 137, 1894, 184—190.

SLAGS low in silica and high in lime and alumina are best suited for cement making. Examples:— $\text{SiO}_2$  25.30—30.00,  $\text{CaO}$  48.00—47.50,  $\text{Al}_2\text{O}_3$  20.10—17.00. The best cement made from such slags is prepared by the addition of about 25 parts of slaked lime to 100 parts of slag by weight. Mortar made of one of cement to three of sand from such cement binds two bricks firmly together, even in the dry air of the laboratory. Test-pieces of such mortar, hardened one day in air and 27 days in water, compare favourably with such mortar for good bought cements. Neat cement test-pieces from the best slags show no shrinkage in the moulds in dry air. These cements set slowly. Their hardness is satisfactory. By far the most complete set of comparisons made was the study of tensile strength at 28 days of neat cement test-pieces, 1 sq. in. in cross section, hardened in dry air, moist air, and water, both for slag cements and bought cements. Four examples selected from the principal table of tensile strain after 28 days, follow. They are the English Portland and the American natural rock No. 1, both in extensive use in this country, and the best two of the slag cements.

Cement.	Tensile Strain.	Kept in
English.....	266	Dry air.
	333	Moist air.
	333	Water.
American, No. 1 .....	88	Dry air.
	109	Moist air.
	79	Water.
Slag cement .....	375	Dry air.
	210	Moist air.
	253	Water.
Slag cement .....	353	Moist air.

*Execution of Masonry and Brickwork during Frost.* A. Griel. Zeits. des Österr. u. d. arch. Ver. 1894, 95. Proc. Inst. Civil Eng. 116, 1894, 9—11.

See under I., page 713.

*Modern Street Pavements.* O. B. Gunn. Journ. Assoc. Eng. Soc., Chicago, 1893, 477. Proc. Inst. Civil Eng. 116, 1894, 41—43.

THE author lays down the following rules for an ideal pavement:—

- 1st. It must be constructed of durable materials.
- 2nd. It must be as free as possible from noise.

3rd. It must present the least resistance to traction (*i.e.* must be smooth).

4th. It must cause the least wear and tear to vehicles and horses.

5th. It should be easily cleaned.

6th. The wearing-surface must be practically non-absorbent.

7th. The cost must be reasonable.

In the United States, as in Europe, street pavements in large cities continue in a period of evolution. Having commenced with native earth as roadways, gravel was next used, and then, successively McAdam, Telford McAdam, cobble-stone, and stone-blocks were evolved; but the constant and intolerable noise arising from the contact of millions of wheels and horses' feet with the granite blocks, which for generations were looked upon as the acme of all pavements, has become such a dreadful nuisance as to cause a general demand in the larger cities for a smoother and less noisy pavement, and the choice now lies mainly between wooden blocks, vitrified brick, or asphalt.

Wooden blocks, 6 in. deep and 4 in. thick, were first introduced in the United States about 40 years ago by Samuel Nicholson, of Boston, and 20 years ago the "Nicholson pavement" was in very general use, especially in Chicago and the cities of the North-West, each layer being separated from the next by a half-inch space which was filled with coal-tar and gravel. In London and in Paris the wooden-block pavements are laid in the most thorough manner, with creosoted or otherwise prepared wood, are kept in perfect repair, and give great satisfaction; but the cost of repairs is greater than with any other pavement.

The busiest streets in London, Paris, and Berlin are formed with asphalt, and it has been also successfully used in New York, Washington, Boston, Buffalo, and other cities in the United States. In Buffalo about 150 miles have been laid during the last 11 years. It is durable, free from noise, presents the least possible resistance to traction, and can easily be kept perfectly clean; but is unsuitable for steep gradients, and can only be laid and repaired by experts who are thoroughly skilled in the manipulation and handling of asphalt. Where it is especially desirable to get rid of noise, if the gradients are steep and the traffic heavy, wooden blocks or vitrified bricks should be preferred to asphalt; their cost is much less than that of granite blocks. In the city of New York about half the asphalt that has been laid is over old stone-block pavements, and several macadamised streets have been covered in the same way.

Vitrified brick is the latest paving material, and is now on its trial with a fair prospect of becoming a prime favourite. It is durable, not very noisy, easily cleaned and repaired, and is quite smooth, presenting small resistance to traction, and is not hard upon vehicles and horses; very close-jointed and nearly non-absorbent. The clay requires careful manipulation before burning, as also improved kilns and methods of burning. Lately some interesting experiments have been made in burning the bricks by electricity, and it is claimed that, in this way, with material of the best quality, a perfect vitrified brick can be produced. The author, however, recommends that instead of using bricks of the ordinary size, their width should be increased to 3½ in.

This material is singularly applicable for the pavement of cities in the prairie States of the West, where neither timber nor stone for paving are at hand, and asphalt would be too expensive; good brick material abounds almost everywhere. In Kansas City its cost would be about two-thirds that of asphalt and only a little more than half that of stone blocks; and, judging from the results obtained from an experience of about four years, such a pavement would carry the traffic of a residential street for 20 years.

No pavement, however perfect in itself, is suitable for all conditions of traffic, and it must be chosen with due consideration to the circumstances; but, on the whole, the author would be inclined to give the first place to asphalt, and the second to vitrified brick.

## PATENTS.

*An Improved Composition of Materials to be used for Making Blocks for Paving, Cement for Walls, and other Purposes of the like kind.* A. Edwards, London. From J. W. Oyster, Louisville, U.S.A. Eng. Pat. 12,791, June 29, 1893.

The composition patented consists of two-fifths its weight of powdered menaccanite, ilmenite, or other titanite mineral; two-fifths of sand, ashes, or other powdered mineral matter; and one-fifth of asphalt or bitumen, with or without a small quantity (about 5 per cent.) of coal-tar. The materials are crushed, mixed, and pressed hot to form blocks suitable for paving, especially for the floors of stables and farm buildings.—B. B.

*Improvements in the Manufacture of Flax or other Vegetable Fibre Roofing.* G. McFearn, Belfast, Eng. Pat. 11,551, July 28, 1893.

VEGETABLE fibre is fed upon a carding drum and thence on to a wire-gauze cylinder, the interior of which is partially exhausted, so that the fibre is formed upon it into a sliver or bat, which is pressed, saturated with bitumen, and faced with a layer of Manilla paper, adhesion being secured by means of bitumen. The product has the merit of possessing a non-absorbent backing which prevents the bitumen soaking out of the fibre and into the woodwork of the roof when exposed to a hot sun.—B. B.

## X.—METALLURGY.

*On the Allotropic Transformation of Iron under the Influence of Heat.* G. Charpy. *Comptes rend.* 113 (1894), 418—421.

UNDER the influence of a permanent deformation in the cold, iron appears to undergo an allotropic transformation, indicated by the existence of a rectilinear step in the curve, serving to indicate the relation between the elongation and the load, when the metal is tested. M. Osmond designates the two modifications as  $\alpha$ -iron and  $\beta$ -iron. If the rod of iron tested is in the state  $\beta$ , the curve will be a continuous one. On the other hand, if it is in the state  $\alpha$ , the curve will contain the step above referred to. If it contains both modifications simultaneously, we can get an idea of the relative proportions of the modifications  $\alpha$  and  $\beta$  present by comparing the length of the step with that given by another bar of the same metal in the state  $\alpha$ . The author has applied this method in investigating the transformation of iron under the influence of heat. Iron in the state  $\alpha$ , when heated to a sufficiently high temperature, becomes transformed into the state  $\beta$ ; but the transformation is reversible, and disappears in cooling. In order to maintain it, the cooling must be done suddenly by plunging the metal into a cold liquid (as in the process of hardening). The author finds that the rapidity of the transformation increases with the temperature. Thus, in the case of hard steel (containing 0.8 per cent. of carbon) no change is produced after heating for an hour to 700° C., or for five minutes to 750°; but the transformation is complete after heating for 30 minutes to 750°, or for five minutes to 800°. Other kinds of steel give similar results. It is clear that in metallurgical operations such as hardening, attention should be paid not only to the temperature, but also to the time during which the metal is submitted to this temperature.—D. E. J.

*Action of Aluminium on Cast-Iron.* *Bull. Soc. Chim.* 11, 1894, 374—379.

It was shown in 1890 by Keep that in order to dissolve ferro-aluminium or pure aluminium in cast-iron, the latter must be melted and run on to the former, which then rapidly

melts and dissolves; it, on the other hand, lumps of ferro-aluminium be thrown on the molten cast iron, they swim up and become covered with a crust which prevents proper fusion and admixture. The addition of aluminium to cast-iron produces an effect different from that observed in the case of steel; instead of increasing the fluidity and lowering the melting point, the mass becomes more and more pasty as the aluminium present increases; even when only low percentages are present there is difficulty in running into moulds, the mass becoming lumpy. Further observations on the subject have been made by Lesclapart and Borsig; commercial aluminium of 92—98 per cent. was plunged into graphite crucibles containing molten cast-iron, by means of tongs, samples of the metal being previously taken for comparison, after skinning. Less than 20 seconds sufficed to effect fusion and solution of the aluminium; quickly-cooled ingots were then prepared in iron moulds 0.5 cm. thick and 12 broad; length variable; and ordinary ingots in sand moulds. The aluminium found in the final product was very much less than the quantity actually added, owing to oxidation; a larger proportion disappeared in the grey iron than in the case of white or mottled; thus in a series of experiments where the aluminium actually used amounted to 0.5, 1.0, and 2.0 per cent. respectively, the following figures were obtained on analysis of the final castings:—

Cast-Iron.	Aluminium added.			Aluminium existing per 100 parts composed.
	0.5 per cent.	1.0 per cent.	2.0 per cent.	
Grey .....	0.027	0.007	0.016	5.0
White .....	0.06	0.085	0.06	9.1
Mottled .....	0.05	0.112	0.06	9.4

As the result of various observations made with the object of investigating the relative effect of re-melting on the material of the crucible, and of the direct oxidising action of the air, the conclusion is drawn that aluminium protects silicon, manganese, and carbon from oxidation by virtue of its own superior oxidisability, and that it is capable of reducing their oxides, and likewise iron oxides; whence, the crucible material is not a matter of indifference. The castings are less liable to contain cavities and blisters due to escape of gases; thus with a white iron, naturally very porous, 0.5 per cent. of aluminium caused nearly all the cavities to disappear, whilst 1.0 and 2.0 per cent. entirely removed them; on the other hand, with 2.0 per cent. the mass thickens notably, so that the metal must be run very quickly in order to fill the moulds. Moreover, the contraction during cooling is apt to cause holes and blisters.

The alteration in resistance to flexure and traction caused by the introduction of aluminium could not be measured at all in the case of white iron; no perceptible effect could be traced with grey iron on comparison with samples of the metal used, drawn before addition of aluminium; with mottled iron, however, a regular increment was noticeable, more especially as regards resistance to flexure; thus when the test bars (30 mm. square in section, 1 metre between the supports) contained 0.05 per cent. of aluminium, the resistance was 28 kilos. per square mm.; whilst at 2 kilos. was the corresponding figure for bars containing 0.16 per cent.

On the whole, the conclusion is drawn that in general aluminium acts on cast-iron like silicon, but less energetically. Its use in iron foundling is but slight, excepting when small quantities can be introduced without considerable loss; for not only is any considerable degree of waste by oxidation costly, but also it brings about various other inconveniences, some of grave character.—C. R. A. W.

*Desilverisation of Lead by an Alloy of Zinc and Aluminium: the Roessler-Edelmann Process.* M. Knortzer. *Bull. Soc. Chim.* 1893, 9 [3], 1033—1037.

THE presence of zinc oxide in the dross obtained by desilverising lead by means of zinc is highly objectionable,

nilitating as it does against the removal and recovery of the zinc by distillation. The ideal product of the process would be an alloy of zinc and silver, free from lead.

The quantity of zinc which will remain dissolved in melted lead is 0·6—0·8 per cent. at 400°, and rather more than 3·0 per cent. at 700°. Zinc at 400° dissolves 1·5 per cent., and at 700°, 5·6 per cent. of lead. In the desilverising process the zinc-silver alloy cannot be freed from lead by liquation because of the presence of oxides, although on a small scale, where oxidation is very limited, such a separation is possible.

An alloy of 95 of zinc and 5 of silver was mixed with lead, in the proportion of 2·6 parts to 100 parts of lead, at 600°. The lead dissolved much of the zinc and but little of the silver, so that the 0·6 part of zinc which rose to the surface contained 20 per cent. of silver; it remained liquid at 600°. An alloy of zinc containing 10 per cent. of silver melts at 500°, and one containing 5 per cent. is nearly as fusible as is pure zinc.

The system devised from the foregoing facts is as follows:—The lead to be desilverised, is heated to 600 and successive portions of zinc, of decreasing silver-content, are added, and skimming effected after each addition. In this way the bath becomes poorer in silver and the alloy more fusible at each skimming; the temperature is allowed to fall from 600° to 400°. The following figures are quoted in illustration of the process:—

100 PARTS OF LEAD CONTAINING 150 GRMS. OF SILVER  
PER 100 KILOS.

#### Additions.

2·6 parts of zinc containing 150 grms. of silver.	
2·1     "     "     "     21     "	
1·6     "     "     "     3     "	
1·1     "     "     "     0     "	

#### Skimmings.

0·6 parts of zinc with 216 grms. of silver, or	Zn = $\frac{3}{1}$
2·4     "     "     53     "     "	45
1·8     "     "     19     "     "	94
1·5     "     "     10     "     "	150
	1

The desilverised lead contained 0·6 per cent. of zinc and 1 gm. of silver per 100 kilos.

The first skimmings can be distilled or electrolysed; the second serves for the first addition in the next operation, and so on.

Whilst the process works smoothly with pure argentiferous lead, the presence of copper, antimony, &c., renders the metal so much more oxidisable that the skimmings contain much oxide and show irregularities in their silver-content. The addition of aluminium, together with the zinc, greatly enhances the resistance of pure lead to oxidation, but its effect on impure lead, particularly if it contain copper, is not so marked; removal of the copper by a preliminary treatment with zinc, will, however, render the aluminium effective.

When the lead is free from copper it is possible to desilverise it in one operation. The zinc-aluminium alloy (0·5 per cent. Al) is melted at a red heat and mixed with lead obtained in liquating previous skimmings; this mixture is then run into the argentiferous lead, heated to the right temperature.

The proportion of alloy added for 0·1, 0·2, 0·4, and 0·7 per cent. of silver are 1, 1·2, 1·4, and 1·7 per cent. respectively, the appropriate temperatures being 450°, 480°, 510°, and 550°. The skimmings are liquated and the resulting crusts contain—

	Per Cent.
Silver .....	20—40
Lead .....	3—4
Copper .....	1·2—2·0
Zinc .....	76—54

They are melted and cast into slabs, which serve as anodes in an electrolytic bath. The electrolytic zinc con-

tains: zinc, 99·94 per cent.; iron, 0·009 per cent.; lead, 0·034 per cent., and a trace of silver. The residues of the anodes contain: silver, 74—80 per cent.; lead, 10—12 per cent.; copper, 1·5—5 per cent.; zinc, 0·2—0·5 per cent.

—A G. B.

*Vanadiferous Liguite found in the Argentine Republic, with Analysis of the Ash.* Prof. Kyle. U.S. Consular Rep., June 1894, 176—180.

The coal is lustrous black, even when finely pulverised, without fibrous structure, and remarkably brittle. On being heated it softens, emits much gas, which burns with a smoky flame, yielding a light, spongy coke, which, after combustion, leaves a singularly small amount of a greenish-coloured ash. The specific gravity of the mineral = 1·173. Its proximate analysis gave:—

Loss on drying at 100°, 2·05; volatile matters, 49·51; fixed carbon, 47·81; ash, 0·63; total, 100.

In the elementary analysis, the carbon and hydrogen were determined by combustion with lead chromate, the nitrogen by combustion with soda lime, and the sulphur by Eschka's method. Its composition, deducting hygroscopic water and use, was found to be as follows:—

Carbon, 60·59; hydrogen, 8·63; nitrogen, 1·43; sulphur, 4·23; oxygen, 25·12; total, 100.

The remarkably small percentage of ash and its peculiar greenish colour naturally attracted attention. On treating it with hydrochloric acid there appeared a deep-red coloration, which, on dilution and heating, changed to a greenish-blue. On addition of ammonia in excess the colour disappeared, showing it had not been due to traces of copper, as was at the first supposed. On further investigation the author satisfied himself that the ash contained vanadium.

The following plan was adopted for quantitative analysis. It is based on a method described by Dr. Adolfo Doering on the "Separation and Quantitative Estimation of Vanadic Acid," published in the Boletín de la Acad. Nacional de Ciencias en Córdoba, Rep. Arg. (Vol. V., p. 117), especially with regard to the separation of vanadic acid from iron and alumina and its precipitation as mercurous vanadate.

One gram. of the ash was repeatedly digested in hot dilute nitric acid; the insoluble silicates and carbon were washed on a tared filter, dried at 120°, weighed, ignited to remove carbon, and the weighed silicates reserved for further investigation.

The nitric acid solution, after removal of excess of acid, was nearly neutralised by sodium carbonate, acetate of sodium added, and on boiling, iron and aluminium phosphates and vanadates were thrown down. The precipitate was dissolved in nitric acid, some sodium phosphate was added, and the phosphates again precipitated by sodium acetate, the vanadium being retained in solution. The mixed phosphates were collected and weighed, the iron contained in these converted into sulphide and weighed as peroxide. The phosphoric acid was estimated, and its amount, plus that of the iron oxide, deducted from the weight of the total phosphates, the difference being regarded as alumina. As the determination of the  $P_2O_5$  included part derived from the added sodium phosphate, that corresponding to the ash was separately determined. The filtrate containing vanadium and excess of sodium phosphate was precipitated by ammoniacal magnesium nitrate, and as the precipitate retained some  $V_2O_5$ , it was redissolved, and the treatment repeated until the magnesium and ammonium phosphate was colourless, the mixed filtrates containing the  $V_2O_5$  were acidified with acetic acid, and the  $V_2O_5$  precipitated by mercurous nitrate. The mercurous vanadate was washed with hot water, collected, and carefully ignited to expel mercury, the residue = 0·034 gm.  $V_2O_5$ .

The filtrate from the mixed precipitates of phosphates and vanadates, thrown down by sodium acetate as previously mentioned, was nearly neutralised by sodium carbonate, and the  $V_2O_5$  precipitated in the hot liquid by mercurous nitrate; the mercurous vanadate on ignition weighed 0·25 gm. On fusion with sodium carbonate and digestion of the melt with hot water, there remained a residue which weighed 0·008 gm. which being deducted = 0·242 gm.

$V_2O_5$ , not combined with iron and alumina. After getting rid of excess of mercury by  $H_2S$ , the filtrate on being neutralised with ammonia assumed a dark colour, and after repose there was formed a very slight precipitate which contained traces of vanadium and manganese sulphides, which were not estimated; the filtrate from these was treated by ammonium oxalate, and the lime estimated as usual; traces of magnesia were found in the filtrate, but not estimated.

It being now apparent that only a small fraction of the vanadium was in combination with iron or alumina, the author treated a fresh portion of ash by digestion in warm ammonia solution, so long as anything appeared to dissolve. The alkaline solution was evaporated in a tared capsule, the residue consisting of calcium sulphate, ammonium vanadate, and vanadates of the alkaline metals. By drying and weighing the residue insoluble in ammonia, which was collected on a tared filter, the amount soluble in ammonia was ascertained. The filter was then ignited and the residue weighed, thus controlling the previous carbon determination. The residue was digested in hot nitric acid, and the solution employed to determine the phosphoric acid by means of molybdate of ammonium.

The mixed vanadates and calcium sulphate left on evaporation of the ammoniacal extract were treated with hot water, much of the calcium sulphate remaining undissolved; the  $V_2O_5$  was precipitated by lead acetate, the precipitate collected on a tared filter and washed with hot water, a few drops of ammonium acetate being added to insure removal of any lead sulphate; the lead vanadate was dried at  $100^\circ$  and treated as recommended by Roscoe (Roscoe and Schorlemmer, "Treatise on Chemistry," Vol. 2, Part 2, 299). As in this method the  $V_2O_5$  is estimated by difference between the weight of the dried lead vanadate and the contained lead weighed as sulphate, the estimation was checked by titration with permanganate of the sulphuric solution, the  $V_2O_5$  having been reduced to  $V_2O_4$  by sulphurous acid. After removal of the excess of lead in the filtrate from the lead vanadate, and of the lime by ammonium oxalate, the filtrate was evaporated to dryness, ignited to expel ammonia salts, the residue moistened with sulphuric acid, again ignited, and the sulphates weighed. The residue dissolved completely in water, the contained  $SO_3$  was on estimation found to correspond to the sulphates regarded as potassium sulphate; the sodium revealed by the spectroscope was therefore a mere trace. As the ash contained no carbonate the lime was calculated as sulphate.

The insoluble silicates were fused with alkaline carbonates, and the melt, being practically free from vanadium, was treated as usual for the estimation of silica and bases.

The composition of the ash after deduction of the carbon (which two separate determinations had shown to amount to 27.8 per cent. in the ash as analysed) may be stated as follows:—

#### Soluble in acid:

Vanadium pentoxide, 38.22; phosphorus pentoxide, 0.71; sulphuric anhydride, 12.06; calcium oxide, 8.44; ferric oxide, 4.98; aluminium oxide, 3.32; potassium oxide, 1.73.

#### Insoluble in acid:

Silicic anhydride, 13.7; ferric oxide, 9.42; aluminium oxide, 5.26; magnesium oxide, 0.83; undetermined traces of manganese, magnesia, chlorine, and loss in analysis, 1.33. Total, 100.

As the analysis of the extract obtained by digesting the ash in hot ammonia water showed that of the total  $V_2O_5$ , viz., 38.22 per cent., no less than 30.6, say 80 per cent., exists either as a vanadium oxide or as a soluble alkaline vanadate, only the remaining 20 per cent. can exist in combination with iron and alumina. When heated on platinum foil to the highest temperature of the blowpipe flame, the ash undergoes partial fusion and acquires a dark-red colour and metallic lustre.

On being boiled with distilled water, a yellow solution is obtained, the yellow colour being probably due to the change of the potassium metavanadate into tetravanadate,

by far the larger part of the vanadium compounds remaining insoluble in pure water, although, as previously mentioned, readily soluble in hot solution of ammonia.

There appears to be no doubt that the vanadium exists in the ash chiefly as vanadic pentoxide, in a free state, partly as potassium vanadate, and also some as iron or aluminium vanadates.

From the foregoing, it is evident that the San Rafael coal is one of great interest, being not only of fair quality as a combustible, but being also available as a source of vanadic acid for industrial purposes, seeing that each ton of the mineral, supposing it to be equal to the sample, will produce over 14 lb. of pure ash, containing  $\frac{1}{2}$  lb. of the vanadic pentoxide, of which 2 lb. may be extracted by simple treatment of the ash with an alkaline liquor, while the remainder is, of course, susceptible of extraction from the insoluble part as in the case of the basic slags of Creusot (Comptes rend. 95, 12-14), which contain but 1.5 per cent.

The ash of the San Rafael lignite is thus the richest known material utilisable as a source of vanadium compounds. Information regarding the carboniferous strata whence the sample of mineral was derived, indicate that the seam is about one metre in thickness.

The Argentine provinces of Córdoba and San Luis are already well known as sources of vanadium minerals, such as vanadite, descloisite, and psittacinite. The province of Mendoza must now be added to the list of localities in the Argentine Republic where vanadium is to be found.

#### The Cyanide Process. W. H. Virgoe. Eng. and Mining J. 1894, 533-534.

THE determination of the sources of waste due to reactions in the leaching vats is a complex and difficult matter. Some ores consume more cyanide than others, and the consumption of this salt is always very greatly in excess of that required by the amount of gold in the material treated. The sources of waste in the leaching vats are similar to those in the storage tanks. A case occurred in Montana, where the leaching of the ore was conducted in covered tanks. The gas volatilised from the solution was so large in amount as to overpower two men engaged in removing the cover after the expiration of the time allowed for the leaching. But, in addition, there are the losses due to consumption of cyanide by base metals in the ore treated. In regard to hematite and limonite ores the consumption of cyanide is usually low. This is also the case with sulphide of iron ores, provided the latter be free from all oxidation. The manganese gold ores of California consume a little more cyanide than the corresponding ferruginous ores. Galena and zinc blends are unattacked. Great difficulty has always been experienced in treating copper ores containing more than 2 per cent. or 3 per cent. of copper, owing to the very heavy consumption of cyanide. A quarter of 1 per cent. solution is invariably the best to be adopted, if ores containing copper must be treated by this process.

Pyritiferous ores are liable to contain, especially when mined above the permanent water level, soluble salts of iron and small amounts of free sulphuric acid. It is necessary, therefore, in treating ores of this description, to first leach them with water in order to dissolve the ferrous and ferric sulphates out, and afterward to decompose the insoluble basic sulphates with a solution of soda-lye or lime water. All mill work should be based upon carefully-conducted laboratory experiments, determining the requisite mesh at which the ore must be treated, the strength of solution necessary, and the length of time for such solution to remain in contact with the ore for the attaining of an economical extraction.

In the zinc precipitation boxes not only does an amount of zinc enter into solution proportionate to the amount of gold and silver and base metals precipitated, such as Cu, Sb, As, &c., thus,  $2KAuCy_2 + Zn = ZnCy_2 + 2KC_2 + Au_2$ , but far more, and the excess is proportionate to the decomposition of the potassium cyanide. Looking at the reactions occurring in an ordinary zinc box, reactions in part purely chemical, in part electro-chemical, involving a

waste of cyanide, it is seen that as soon as the gold is deposited on the zinc shavings, galvanic action is at once established between the electro-negative gold and the electro-positive zinc, hydrogen is vigorously evolved at the negative pole and the zinc converted into hydrate, which in turn is immediately attacked by the excess of potassium cyanide, forming zinc potassium cyanide and potash—

As this reaction is incessantly occurring, the solution becomes very strongly alkaline in the lower compartments of the zinc boxes. This galvanic action is a source of a large loss of cyanide, not only by causing the formation of the double salt of zinc and potassium cyanide, but undoubtedly by causing the oxidation of a certain quantity of potassium cyanide to cyanate.

The majority of mills make a mistake in not discarding screens made of fine iron wire in the compartments of the precipitation boxes, because there is a strong galvanic action established immediately between the zinc and the iron so soon as the cyanide solution flows through them, hindering the deposition of gold and silver and augmenting to a marked degree the loss of cyanide through solution of the zinc, besides largely increasing the zinc slimes in the product and making them more difficult to handle. Commercial zinc is only slightly soluble in potassium cyanide, but in contact with iron it is readily dissolved, especially in the lower compartments of the precipitation boxes, where the solution is most strongly alkaline. This reaction is thus expressed:—

Again, the majority of boxes in use are far too long. There is no advantage to be gained in using boxes 20, 30, and 40 ft. in length.

Precipitation takes place mainly in the upper compartments, after which the solution is unnecessarily exposed to the action of the zinc. Short boxes and plenty of them is the right motto.

These are, in a general way, the merits and disadvantages connected with the cyanide process. That there is a great future before it in America the writer has every confidence, and in the interests of mine owners and millmen, it is to be hoped that under the present organisation success may be achieved.

*Notes on the Cupellation of Bismuth-Silver Alloys.* E. A. Smith. Proc. Chem. Soc. 1894 [139], 117.

See under XXIII., page 765.

*The Conditions in which Carbon Exists in Steel.* J. O. Arnold and A. A. Read. Proc. Chem. Soc. 1894 [138], 105—106.

THE authors have carried out experiments on the condition in which carbon exists in normal, annealed, and hardened steel on a series of five steels containing 0.26, 0.57, 0.33, 0.16, and 0.6 per cent. of carbon respectively.

The method they have used in their determinations is a modification of the process of Binks and Weyl, originally proposed for the estimation of carbon in iron.

Two bars of polished steel of suitable size were suspended in separate beakers containing dilute hydrochloric acid (rel. dens. 1.02), placed in the same circuit, and connected with the positive pole of a single Bunsen cell, the cathodes being plates of platinum placed in a flat porous cell. At the end of the time allowed for solution the carbide was collected on a smooth filter paper and washed with water, alcohol, and finally with ether. The residue was washed off the filter paper into a weighed boat, and then dried in a vacuum. The carbon was estimated by direct combustion, the residue afterwards being used for the estimation of the iron.

From the results of a number of experiments the authors draw the following conclusions:—

1. The existence is confirmed of a carbide of iron possessing the formula  $\text{Fe}_3\text{C}$ , originally discovered by Abel and Müller by independent methods.

2. The normal carbide exists in two different forms—identical in chemical composition.

(a.) A diffused carbide is scattered in granules or very small plates throughout the iron in normal steel. When isolated it is a greyish-black powder.

(b.) A crystalline carbide, arranged in comparatively large distinct plates in well-annealed steel; these plates are chiefly in the form of well marked striae, and consist of pure  $\text{Fe}_3\text{C}$ . They are identical with the microscopical laminae of Sorby's "pearly" constituent, and they may be isolated as bright silver plates.

3. The percentage of the total carbon obtained as carbide is greater in hard than in soft steels.

	Per Cent.	Per Cent.	Loss per Cent.
In iron containing ....	0.1	92	8
" " ....	0.5	87	13
" " ....	0.25	74	23

4. The above-mentioned loss does not appear to be due to decomposition, but rather to the presence of a readily decomposed sub-carbide of iron (containing less carbon than the normal compound) existing to the extent of about 25 per cent. in mild steel, and capable of existing to the same amount in cold, hard steel after the latter has been heated for some time at a white heat.

5. The loss being practically the same in well-annealed steel as in the normal steel, it cannot be due, as supposed by Ledebur, to the presence of "hardening carbon."

6. The carbon in hardened steel exists chiefly as an extremely attenuated carbide, or in solution, leaving on isolation a residue consisting mainly of "hydrate of carbon," mixed to a slight extent with carbide of iron. Whether the large loss of carbon (about 50 per cent. of the total) occurring during the galvanic decomposition of the hardened steel is due to the presence of a large percentage of sub-carbide or to evolved hydrocarbons, formed by the action of nascent hydrogen on the finely-divided free carbon, there is no conclusive evidence to show.

The authors have also experimented on a steel containing 1.73 per cent. of manganese and 0.55 per cent. of carbon, and find that a portion of the iron is replaced by manganese, the double carbide apparently having the formula  $\text{Fe}_2\text{MnC}_3$ .

In the discussion following, Prof. Roberts-Austen observed that this was only a portion of a long series of experiments, many of which appeared to have been very carefully made. He regretted, however, to say that he entirely differed from the conclusions at which Mr. Arnold had arrived. He was not prepared to raise objections to the method employed, which, under the circumstances, was probably as good as any that could have been adopted; it was, moreover, a method which the speaker had himself used 30 years ago. He quite believed in the existence of Abel's carbide of iron,  $\text{Fe}_3\text{C}$ , but he considered that the authors of the paper had not offered any evidence which could be accepted in support of the presence in the steel of a new sub-carbide of iron. Without the exercise of the utmost care and absolute uniformity of conditions, nothing is easier than to lose carbon when steel is dissolved by electrolytic action.

## PATENTS.

*Process of and Apparatus for Separating Metals and similar Substances.* J. A. Mays, London. Eng. Pat. 2639, February 7, 1893.

THE metals or other substances are caused by centrifugal force to arrange themselves within a revolving chamber, while molten, in layers concentric to the axis of rotation, those of greatest specific gravity being farthest from such axis and *vice versa*. The metals may either be melted in

the revolving chamber itself or before their introduction thereto. In some cases traps, siphons, or passages are disposed in or around the chamber whereby each separate substance is let off into a suitable collector. Devices for cooling, granulating, and condensing are sometimes added.

—J. H. C.

*Improvements in the Purification of Iron for Casting and General Foundry Purposes, as also in the Production of Steel and Wrought Iron.* J. B. Cochrane, Stourbridge, and T. H. Taylor, Dudley. Eng. Pat. 11,709, June 14, 1893.

In treating iron for foundry and general casting purposes, a floating ball or brick composed of calcium fluoride or other halogen compounds, such as calcium, sodium, or ferric chlorides, together with an oxide, carbonate, or hydrate of an alkali, metallic iron and chloride of ammonium, is thrown into the ladle at the commencement of or during the filling, and the metal is desulphurised as it rises.

In treating iron for conversion into steel a similar ball is placed either in the ladle or in the furnace or converter, and in converting crude pig iron into wrought iron the ball is introduced at the melting or other period of the conversion.

The following proportions answer very well with a moderately sulphurous iron:—

	Per Cent.
Iron.....	35-50
Fluoride of calcium.....	28-12
Lime.....	50-15
Sal ammoniac.....	1-2

The materials are thoroughly ground or mixed together with water, moulded into the required size and shape, and dried.—J. H. C.

*Improvements in the Treatment of Lead Fumes.* G. Bischof, London. Eng. Pat. 12,034, June 19, 1893.

THE gases which carry the fumes are made to pass through a deep fire of carbonaceous material, or they are mixed while hot with combustible gas or vapour and passed through porous refractory material, such as fragments of coke or of brick free from silica. In either case metallic lead will be deposited.—J. H. C.

*Improvements in the Metallurgy of Metallic Sulphates.* W. Mills, London. Eng. Pat. 12,647, June 28, 1893.

THE invention has for its object the preparation of metals such as magnesium, calcium, aluminium, barium, potassium, and sodium by decomposing their salts in the presence of sulphuric anhydride and a reducing metal such as zinc, iron, tin, or lead.—J. H. C.

*An Improved Process for Treating Complex and Refractory Ores and Materials, and Obtaining the Metals and Pigments therefrom.* J. W. Hall, Bristol. Eng. Pat. 12,979, July 3, 1893.

THE ores are subjected to a strong blast, preferably hot, upon an open Scotch hearth or other suitable furnace, and the fumes containing the volatilised metals are drawn by a fan or otherwise into a settling tower or chamber through sheet-iron tubes or other cooling media into strainers made of suitable textile fabric. The fumes so obtained are utilised direct or further treated. For certain classes of ore rich in silver or gold, lead material is added, and for ores poor in the precious metals a cupola furnace is sometimes used instead of the Scotch hearth.—J. H. C.

*Improvements in the Manufacture of what is known as Manganese Steel.* R. A. Hadfield, Sheffield. Eng. Pat. 13,847, July 17, 1893.

THE improvement consists in bringing the ferro-manganese and the ordinary steel together, and mixing them in a ladle or vessel such as is adapted by suitable weighing mechanism

to show the weight of its contents, the ferro-manganese and the steel being added separately and successively so that the weight of each, and consequently the proportions thereof, can be easily controlled.—J. H. C.

*Improvement in Dissolving Leaching, and Filtering Ores or Minerals, and Apparatus therefor.* J. F. Phipps, O. Tinsley, London. Iron B. F. 4,637, Soc. London, and J. Storey, Sydney. Eng. Pat. 15,940, August 23, 1893.

STEAM or other elastic fluid is applied to cause the liquid solvent to pass repeatedly through the material to be dissolved or the solution to pass through a filter.—J. H. C.

*Improvements in the Art of Producing Metallic Zinc.* P. C. Choate, New York. Eng. Pat. 8985, April 24, 1894.

ZINC is volatilised as fume by heating its ores with a reducing agent in a furnace in the presence of air. This fume is heated with carbon at a moderate temperature, so as to eliminate any metallic constituents which are more volatile than zinc. It is finally reduced, distilled, and cast into anodes of suitable form.

The zinc anodes so prepared are immersed in a zinc sulphate solution containing a little soluble chloride; the cathodes may be plates of zinc, copper, or other suitable metal. On passing a current of electricity pure zinc is deposited, while any antimony, arsenic, copper, silver, gold, &c., present will be separated and will settle in the bath.

—J. H. C.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*Electrical Smelting.* Consul-General Mason. U.S. Consular Report, June 1894, 237-240.

ONE of the most interesting processes, by reason of its simplicity and its probable value in practical application, is one invented by Edward Taussig, of Bahrenfeld, Germany, for the smelting and casting of metals by electrical heat, under the influence of rarefied air. The operation consists in fusing ores or metals in a closed furnace or chamber, the hearth of which is connected with moulds, into which the fused metal flows by gravitation, and is cast into any desired form, and in both of which (moulds and furnace) the air has been rarefied as far as practicable through exhaustion by air pumps or other mechanical means.

The apparatus includes a long, air-tight smelting channel or chamber, the hearth of which inclines to a central orifice, through which the fused metal passes into the moulds. This chamber is filled with the metal to be smelted, and heat is generated by passing an adequate current of electricity through the mass without the use of any kind of fuel, or the employment of carbon electrodes.

The furnace is lined with glazed fire bricks, which are so efficient a non-conductor as to insulate quite perfectly the contents of the chamber, so that the heat is developed where it is required evenly throughout the mass, and very little, if any, loss of current is experienced. From the testimony of experts who have examined this process in operation, it appears that a degree of heat sufficient to smelt pig iron in 15 minutes can be generated and maintained without unduly heating the other parts of the circuit, and this is equally true of the smelting of easily-fused metals like lead and zinc, and of Siemens-Martin steel of Swedish origin, which is known to be one of the most refractory of all the useful metals.

The entire absence of coke, coal, or carbon electrodes secures to the fused metal nearly absolute purity, and the

continued exhaustion of air and the gases generated by smelting increases the fluidity of the molten material and wholly prevents oxidation and blistering, and produces castings of a dense, smooth quality, which have shown, under elaborate tests, the highest mechanical qualities of which cast iron is capable.

For smelting raw ores, the most obvious advantage claimed for the process is that it can be worked wholly by water power and without fuel in mountainous and remote districts, which produce ores and have abundant water, but no coal.

(1.) It has been shown that by this process a degree of heat sufficient to smelt a ton or more of iron within 15 minutes may be generated, sustained, and applied at will without the use of carbon electrodes and without excessive heating or injury to other portions of the circuit. This alone is a fact of dominant and far-reaching importance.

(2.) Castings of iron and steel, up to a weight of 200 pounds or more, have been made which have shown all the desirable qualities—smoothness of surface, fineness of texture, and freedom from many of the impurities which are always more or less incident to smelting by ordinary methods.

(3.) Pig iron of excellent quality has been produced in small quantities by direct smelting from Swedish ores. The tests of this iron, as made by the Royal School of Mines at Berlin, have been published in several technical journals. The tables are too abstruse and complicated to be of general interest, but the net results may be summarised in the statement that the tractile strength of a round rod 10 millimetres in diameter was 3,410 pounds, and the resistance to compression of a rod 301 millimetres in length and 30 millimetres in diameter was 57,850 kilos., or 127,270 pounds.

*On the Minimum Electro-motive Force required for the Electrolysis of dissolved Salts of Alkalis.* C. Nourisson. Comptes rend. **118** (1894), 189—192.

BERTHELOT has shown that in discussing electrolytic actions there is no need to separate the primary from the secondary reactions: all that is necessary is to take into account the initial and final states of the solution. Taking, for example, sodium chloride, and assuming that there is total decomposition and then total combination (starting with the elements), we distinguish four reactions, which together constitute the electrolytic action:—

	Calories.
(1) $\text{NaCl} = \text{Na} + \text{Cl}$ , with absorption of...	96.4
(2) $\text{H}_2\text{O} = \text{H}_2 + \text{O}$ " " "	68.4
	<hr/> 164.8
(3) $\text{Na} + \text{O} + \text{H} + \text{Aq} = \text{dissolved NaOH}$ , with evolution of.....	117.8
(4) Formation of oxy-compounds of Cl.....	6.0
	<hr/> 117.8

The difference is  $164.8 - 117.8 = 47$  calories, and the current must therefore supply work corresponding to 47 calories, in order to decompose one equivalent of sodium chloride (it being of course assumed that it does nothing but electrolytic work). The electro-motive force would thus be  $\frac{47}{23.2} = 2.02$  volts, which is known to be sufficient for the electrolysis of sodium chloride. Similarly for sodium bromide we find 1.75 volts, and for sodium iodide 1.46 volts.

Taking next an oxy-salt, the data for sodium sulphate are as follows:—

	Calories.
(1) $\text{Na}_2\text{SO}_4 = \text{S} + \text{O}_4 + \text{Na}_2$ , with absorption of....	329.6
(2) $2\text{H}_2\text{O} = 2\text{H}_2 + \text{O}_2$ " " "	137.8
	<hr/> 467.8
(3) $\text{S} + \text{O}_3 + \text{Aq} = \text{dilute H}_2\text{SO}_4$ , with evolution of...	112.5
(4) $\text{Na}_2 + \text{O}_2 + \text{H}_2 + \text{Aq} = \text{dissolved NaOH}$ , with evolution of.....	223.6
	<hr/> 346.1

The difference is 99.7 calories. According to these equations we have left,—hydrogen at the cathode and oxygen at the anode. The result is the same if we assume that the only effect of the current is to decompose the water and separate the sulphate into free base and acid; thus:—

	Calories.
Decomposition of water.....	68.4
Neutralisation of sulphuric acid.....	31.4
	<hr/> 99.8

As sulphuric acid is dibasic, we must divide this result by two. Thus, an E.M.F. of  $\frac{99.8}{2 \times 23.2} = 2.15$  volts, is the lowest which will decompose sulphate of soda. Similarly, both the nitrate and the chlorate of soda are shown to require 48 calories or 2.07 volts.

Applying to the above results the laws of electrolysis, and also certain well-known thermo-chemical data, the author deduces the following general law:—The minimum electro-motive force required for the electrolysis of a dissolved salt of an alkali is constant, on the one hand for all oxy-salts, and on the other hand for all the haloid salts derived from the same acid.

The author has experimented on a large number of salts (using the current from a secondary battery, with a voltmeter graduated to fiftieths of a volt), and he gives data confirming the law above quoted.—D. E. J.

*On the Minimum Electro-motive Force required for the Decomposition of Electrolytes.* Max Le Blanc. Comptes rend. **118** (1894), 411—412.

THE author refers to M. Nourisson's paper (preceding abstract), and points out that he had arrived at the same results (starting from Arrhenius's theory of electrolytic dissociation) some three years ago, and had verified them experimentally.—D. E. J.

*Observations on the Preceding Note (on the Limits of Electrolysis).* M. Berthelot. Comptes rend. **118** (1894), 412—415.

REFERRING to the papers by MM. Nourisson and Le Blanc, M. Berthelot draws attention to the fact that their experiments are in exact accordance with those in his own memoir "On the Limits of Electrolysis," published in 1882. In this memoir he gave experimental proof that the E.M.F. required for the electrolysis of a salt of an alkali is the sum of two quantities: one equivalent to the heat absorbed in the separation of the acid and base in dilute solutions, the other equivalent to the heat of decomposition (into hydrogen and oxygen) of the water in which the substance is dissolved. This result is not based upon any theory as to the constitution of electrolytes; it is an experimental law, independent of all hypothesis. Of course it only holds good provided that neither the acid nor the base is oxidised or reduced during the operation. It proves that, under these conditions, the electro motive force depends upon the difference between the initial and final chemical states. The author in especial points out that his results were obtained quite independently of Arrhenius's hypothesis of electrolytic dissociation.

—D. E. J.

*Formation of Aluminium Sulphide.* F. Gruy. Zeits. angew. Chem. 1894 [10], 290—291.

BACHERER has shown (this Journal, 1893, 272; 1894, 42) that aluminium sulphide is a convenient compound for the preparation of pure aluminium by electrolysis. It has many advantages over the oxide, the chief of which is that considerably less energy is required for its decomposition than for that of the oxide (*loc. cit.*).

Hitherto aluminium sulphide has only been prepared on a small scale, as it had no technical value. A mixture of carbon and alumina is heated to a white heat and sulphur vapour passed over it. This process is not a convenient one for the preparation of the sulphide in quantity. The oxide employed must be free from iron and from silica. The

use of sulphur increases the cost of the manufacture as it is impossible to prevent considerable loss of this substance. A very good bath for the electrolytic decomposition of aluminium sulphide is obtained in the following way:—When the double chloride of sodium and aluminium is added to fused sodium sulphide, aluminium sulphide and sodium chloride are formed. The fluoride of aluminium behaves in the same manner as the chloride, thus:—

In this way it is possible to obtain an aluminium bath direct from cryolite. By the use of cryolite, however, the process is not cheapened; this can only be attained by employing other substances as raw material. Among other substances clay may be used as a raw material. By decomposing clay with sulphuric acid, aluminium sulphate is obtained. When this is fused with sodium fluoride, aluminium fluoride or cryolite is formed, thus:—

or

The isolation of the aluminium fluoride is impracticable; it is expedient to reduce the sodium sulphate to sulphide, which is accomplished by dropping carbon into the molten mass. The sodium sulphide thus formed interacts with the aluminium fluoride, forming aluminium sulphide and sodium fluoride. The separation of the latter from aluminium sulphide is quite superfluous, as this mixture can obviously in the molten condition be used as an electrolytic bath.

It is to be observed, however, that both sodium fluoride, as well as sodium sulphide, attack all fireproof materials, thereby rendering the melt impure. This may be avoided by employing a furnace, that portion of which coming into contact with the melt being of iron, and furnished with a water-cooling arrangement. In this case a crust forms on the surface of the iron, which protects the latter from the corrosive action of the melt.—A. R. L.

*Desilverisation of Lead by an Alloy of Zinc and Aluminium, the Roessler-Edelmann Process.* M. Knoertzer. Bull. Soc. Chim. 1893, 9—10, 1033.

See under X., page 737.

*The Electrolytic Separation of Gold from Silver.* C. Schnabel. Zeits. des Ver. deutsch. Ing. 1893, 653. Proc. Inst. Civil Eng. 116 [ii.], 1894, 86—87.

At the works of the Saint Louis Smelting and Refining Company an electrolytic method of refining has been substituted for the method of parting by sulphuric acid in the treatment of auriferous silver, containing  $\frac{1}{10000}$  of gold (28.8 grains per lb. troy). The silver is cast into plates measuring 10 by 8 by  $2\frac{1}{2}$  inches, two of which are placed together in a linen bag to form one anode, with a rolled plate of fine silver for a cathode. The dissolving vessels are wooden vats, divided into seven cells and rendered impermeable by a coating of bitumen, each vat containing 70 pairs of electrodes arranged in series. The electromotive force required for each bath is  $1\frac{1}{2}$  volts, with a current of 350 amperes per square metre, which is furnished by a dynamo of 100 volts and 200 amperes driven by a 30-h.p. Westinghouse engine. The electrolyte used in the first instance is water containing one tenth per cent. of nitric acid, which is made up with very weak solution of silver nitrate as the operation progresses.

The anodes are entirely dissolved in from 30 to 40 hours; the reduced silver separates in a crystalline form, shooting across from the anode to the cathode, so that short-circuiting very frequently occurs. To meet this difficulty an apparatus is used for scraping the deposit off the cathodes at intervals, which, at the same time, keeps up the circulation of the solution in the bath. The deposited silver so removed falls to the bottom of the bath into boxes with double bottoms, perforated and covered with linen, for collecting the precipitate, which is removed once a day. The finely-divided gold is kept back in the anode bags, where it is allowed to accumulate for a week before cleaning out. It is then boiled with nitric acid, washed, dried, and

melted with a little sand or borax, giving a brilliant 999 fine. The silver, after washing and drying, is found to be free from gold, and assays 999.5 fine. The silver nitrate obtained from the final treatment of the gold is used to keep up the bath to the proper strength. At Saint Louis 933 kilos. silver (about 30,000 ozs.) are parted by this method daily, and at Pittsburgh a still larger plant of 40,000 ozs. capacity is in use. At the latter place the finely divided gold is melted with a small quantity of silver before being subjected to the final boiling with nitric acid.

As compared with acid parting, the electrolytic method, which has lately been adopted in Europe by the Frankfurt gold and silver refinery, is cheaper and quicker, the whole operation being completed in 48 hours; causes less loss of silver, and can be worked without producing the injurious gases which are unavoidable when sulphuric acid is used. It can be applied with profit to silver containing  $\frac{1}{2}\%$  of gold as a minimum.

## PATENTS.

*A Process for Maintaining Positive Plates of Secondary Voltaic Batteries in Good Operative Condition.* E. Epstein, East Twickenham, Middlesex. Eng. Pat. 4106, February 24, 1894.

This invention relates to a process whereby, when the oxides upon positive plates become soft and liable to be washed off when the battery is agitated, they are hardened by removal from the cell, drying them, and then subjected to reduction and reoxidised electrolytically and replaced in the cell. Where both positive and negative plates are capable of such treatment they may be similarly treated by drying and reversal of current.—J. C. R.

*Improvements in the Manufacture of Elements or Electrodes for Voltaic Batteries and Electrolytic Decomposition Cells.* D. G. FitzGerald, London. Eng. Pat. 9906, May 17, 1893.

These improvements consist in treating lead oxides with a solution of one or both of the fixed hydrates of the alkalis—caustic soda and potash—and carbonating the alkali by exposure to an atmosphere containing carbonic acid, by which a dense, coherent, and non-disintegrating mass may be obtained.

The following are slightly abridged examples:—

A. Litharge, massicot, or minium, alone or mixed; caustic potash solution, sp. gr. 1.100 to 1.150, sufficient to form into a stiff paste, and then moulded; subjected preferably to a current of air for three days, which carbonates the alkali, partially dries the plates, and precipitates any oxide in solution, and the material "sets." The set plates are dipped, at least twice, for a few seconds in a solution of sulphate of magnesia, half saturated or more dilute, at intervals of a day or more, and dried by exposure to air after each immersion. The solution for last immersion more dilute and slightly acidulated with sulphuric acid, the plates left in this solution for some hours to dissolve out precipitated magnesium hydrate, and then stood in racks to drain, dry, and "season." Caustic soda may be employed instead of the potash, but undesirable on account of efflorescence, and if used with caustic potash the latter in larger proportion.

B. For plates of greater porosity. Lead oxides (as above) in a slightly damp condition pressed in a mould between linen or felt containing enough moisture to cause the surface particles to cohere, to allow of the subsequent treatment of the mass within the mould, or supported on a plate of glass, with an alkaline solution, as above, gently poured over the moulded mass. Subsequent exposure to carbonic acid and treatment with sulphate solution, as above described.

C. A mixture of any lower oxide or oxides of lead with peroxide of lead is used, containing 25 per cent. or more of the latter, made into a paste with caustic solution, or moulded dry and treated with caustic solution. Treatment with alkaline solution causes the plate or mass to set hard

and porous, even without the intervention of carbonic acid, so that exposure to that gas for a longer period than a few hours, and subsequent treatment with sulphate of magnesia, are not in this case essential. To produce the setting effect with certainty, the proportion of the lower oxide present should not be less than, say, 10 per cent.

The plates may be reduced or peroxidised by ordinary means, but the inventor prefers a method which forms the subject of another Eng. Pat. 11,983, June 17, 1893.

—J. C. R.

*Improvements in Plates or Elements for Secondary Electric Batteries.* The Lithanode and General Electric Company, Limited, and J. T. Niblett, London. Eng. Pat. 13,218, July 6, 1893.

According to this invention the active material which is employed is in the form of plates, slabs, or pellets, is of a coherent nature, being preferably that which is known as "lithanode," and of any desired shape, as square, triangular, hexagonal, cylindrical, around the edges of which grooves, which may be V-shaped, recesses, or holes are formed, by which a number of them are firmly locked together to form a large plate by a conductor cast therearound, itself exposing little surface at the face of the plate. Another plan is to groove the slabs on both faces, with holes extending from the grooves on one face to the grooves on the other face, so that the metal when run in fills these grooves and connecting holes.—J. C. R.

*Improvements in the Manufacture of Plates for Electric Accumulators.* C. Rousseau, Paris, France. Eng. Pat. 13,274, July 7, 1893.

According to this invention, lead plates are moulded with ribs and then, by mechanical means, transverse or oblique cuts or slits are made in the ribs so as to form teeth or projections, more or less sharp, which are designed to be beaten down over the paste or active material to retain it in contact with the lead plate or core.—J. C. R.

*An Improved Electrolytic Process for the Production of an Alloy of Lead and Sodium or Potassium.* C. T. J. Vautin, London. Eng. Pat. 13,568, July 12, 1893.

This invention consists essentially in the employment of lead in a molten condition as a cathode in a fused salt of sodium or potassium as electrolyte, by which, on electrolysis, an alloy of lead and sodium or potassium is obtained, the products given off at the anode being collected, if of value (this Journal, 1894, 449).—J. C. R.

*Improvements in Plates or Electrodes for Accumulators.* R. J. Gülicher, Charlottenburg, Germany. Eng. Pat. 6947, April 7, 1894.

These improvements consist in introducing the active substance on and between the fibres of woven or knitted fabrics, such as felt, the fibres being of either natural or artificial origin, so that the effective layer thus formed is porous, firm, and flexible, and the electrolyte easily penetrates into the interior portions, producing an even action on all the parts. It is preferred to produce on and between the fibres—sheep's wool, slightly or not at all felted—of the form and size of the plates to be produced, a spongy lead by chemical means, as an oxide reduced by an electric current in an electrolyte of weak sulphuric acid, or impregnated with sulphate of lead produced in the fibre by its first being saturated with a solution of lead acetate, and then placed in a bath of diluted sulphuric acid, or pressing a paste of sulphate of lead prepared with distilled water thoroughly into the fabric and covering its surface. The sulphate so applied to the fabric is reduced to spongy lead by zinc in a solution of common salt or weak sulphuric acid, and to prevent adherence of the reduced lead to the zinc plates, sheets of filter paper are introduced between them and the impregnated fabric.—J. C. R.

*An Improved Method, Means, or Process of Producing Caustic Soda and Chlorine Gas by the Electrolysis of Common Salt in Solution.* T. Drake, Ruddersfield. Eng. Pat. 7985, April 23, 1894.

This invention relates to the method of decomposing common salt solution to obtain chlorine and soda, employing a mercury cathode and an anode of carbon. The former is shown contained in an iron vessel, the inner walls or sides of which are "carbursed," with water circulating above it to dissolve out the sodium, and the anode, in a solution of common salt, contained in a porous pot in the middle. Arrangements are described for circulating both water and brine.—J. C. R.

*Improvements in the Electrolytical Production of Nickel and other Metals.* C. Hoepfner, Giessen, Germany. Eng. Pat. 13,336, July 8, 1894.

These improvements relate to methods of obtaining cobalt and nickel from their solutions, neutral or slightly acidulated with bad conducting acids, as citric or phosphoric, electrolytically, by placing them next cathodes, which may be movable, as rotating or oscillatory, and provided with brushes or rubbing cushions; and next the anode, which may be soluble or insoluble, a solution of a metal which is electro-positive to them, as chlorides of sodium, potassium, or calcium. An insoluble anode may be replaced by a soluble one, as zinc, more electro-positive than cobalt or nickel. Between the electrodes there may be placed membranes of nitro-cellulose, "nitro-cloth, nitro-linen," sometimes mixed with asbestos, backed on the cathode side by an open grating or sieve. It is proposed to obtain zinc, lead, tin, and copper from their solutions in a similar manner. In the case of copper, cuprous chloride being preferred, as yielding double the quantity of the cupric salts, and of better quality.—J. C. R.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*Carnaüba Wax.* A. M. Villon. Bull. Soc. Chim. 1893, 9, 1046—1048.

Each leaf of the *Copernicia cerifera* yields 7 grms. of carnaüba wax: the leaves are beaten and the dust from them is melted.

Carnaüba wax is yellowish, hard, brittle, and lustrous; its specific gravity is 0.999; it melts at 84°—85°, and dissolves in alcohol and in boiling ether. It must not be confounded with the palm-wax (*Lerxylon andicola*) from New Grenada, which melts at 72°.

The wax is bleached for candle-making by filtration through animal charcoal, or by hydrogen dioxide, or by potassium bichromate. For the second process the wax is granulated and immersed in hydrogen dioxide (5—10 vols.), saturated with ammonia or sodium carbonate, and kept at 50°; the addition of 0.5 per cent. of borax aids the bleaching. Candles are seldom made of carnaüba wax alone; stearine and ozokerite are generally added to the extent of 20—30 per cent.

"Brilliant paraffin" contains paraffin, 75 per cent.; carnaüba wax, 25 per cent.

"Brilliant gelatin" is prepared by adding a liquid containing water (10 litres), potassium carbonate (1 kilo.), and carnaüba wax (4 kilos.) to a solution of gelatin. The product is used in finishing leather.

Carnaüba wax varnishes are made by saponifying the wax with potassium carbonate containing a little caustic potash, precipitating the solution by the salt of a heavy metal, and dissolving the precipitate in light petroleum or spirit of turpentine.

Carnaüba wax is employed for making phonograph cylinders.—A. G. B.

*Notes on the Examination of Beeswax.* Lyman F. Kebler, J. Franklin Inst. **137**, 1894, 58-59.

Beeswax in American markets is adulterated, according to the author, to the extent of 50 per cent., whilst in the English markets the amount of adulteration rises to 66 $\frac{2}{3}$  per cent.

The melting point of beeswax varies from 62 to 64 °C. It is raised by adding carnauba wax, stearic acid, certain mineral waxes, and paraffins.

China wax, Japan wax, cacao butter, resin, tallow, spermaceti, vegetable wax, certain stearic acids, and paraffins lower it, whilst it is apparently unaltered when adulterated with suint wax, certain mineral waxes, paraffins, and stearic acid.

The specific gravity of beeswax varies from 0.960 to 0.973, and appears to be greatly influenced only by resin, carnauba wax, and certain mineral waxes, which increase it, and by paraffins, which lowers it.

The "acid number" ranges from 19 to 21 mgrms. of potash per gram. of beeswax. Stearic acid, resin, and suint wax increase, whilst carnauba wax, mineral wax, cacao butter, paraffin, and spermaceti decrease the acid number. China wax, Japan wax, and vegetable wax do not vitiate the number seriously. The following is a table embodying the properties of the various substances employed in adulterating beeswax. Some of the data are due to the author, the rest to Dietrich, Dammer, A. and P. Buisine (this Journal, 1891, 52 and 53, also 728-729), and Benedikt:—

Substance.	Melting Point.	Specific Gravity 15° C.	Acids Sol. in Water.	Acid Number.	Ether Number.	Total.	Iodine fixed by 1 gram. of Wax.	Vol. of H at 0° C. and 760 mm. yielded per gram.	Hydrocarbons from 1 gram. of Wax.
Yellow beeswax...	62-64	0.961-0.964	0-1	19-21	73-76	91-97	8-11	53-57.5	12.5-14.5
Beeswax bleached by various agents.	63-64	0.960-0.973	0-2	19-23	74-84.20	94-107.7	1.8-11.30	51-57	11-14.3
Cacao butter.....	30-33	0.945-0.952	0	0-3	132-200	132-204	34	..	..

China wax.....	53.5	0.970	2	22	196	218	0.85	72.0	0
Japan wax.....	47-54	0.975	2	18-28	194-198	216-222	0.755	60-71	0
Mineral wax.....	60-80	0.918-0.952	0	0	0	0	0-0.6	0	100
Paraffin.....	38-74	0.913-0.914	0	0	0	0	17-31	0	100
Resin.....	53.5	1.104-1.108	0	168	10	178	135.6	35	0
Spermaceti.....	40-50	0.945-0.96	0	0-2	136-142	136-144	..	..	..
Stearic acid.....	53.5-59.2	0.900-1.00	0	204	5	209	2-4	0	0
Suint wax.....	62-66	..	0	95-115	4-7	102-119	13-18.5	0	14-18
Tallow.....	42-50.5	0.952-0.96	0	2.75-5	193-208	196-213	27-40	52-60	0
Vegetable wax....	47-55.6	0.947	2	17-19	203-210	218-220	6.6-8.2	73-74	0

The "ether numbers," varying from 73 to 76 mgrms. of potash per gram. of beeswax, are unaffected by adding carnauba wax; but China wax, Japan wax, cacao butter, tallow, vegetable wax increase it. Mineral wax, paraffin, rosin, stearic acid, and suint wax decrease it. It must be noted that wax bleached by certain chemical agents may have an ether number as high as 84 and yet be pure.

The percentage of iodine varies from 8 to 11, yet wax bleached by certain agents, as chlorine, may vary far from these percentages. Paraffin, mineral waxes, and stearic acid lower the percentage, but cacao butter, rosin, suint wax, and tallow increase it. China wax, carnauba wax, Japan wax, and vegetable wax pass the prescribed limits but very little.

The volume (53 to 57.5 c.c.) of hydrogen evolved from 1 gram. of beeswax and the percentage (12.5 to 14.5) of hydrocarbons evidently are the most reliable data to be secured; the former being vitiated by all adulterants except tallow, and the latter by all except suint wax.—W. S.

*Continuous Purification of Oils.* A. M. Villon. Bull. Soc. Chim. 1893, **9**, 1037-1038.

THE oil and purifying liquid, generally sulphuric acid, are caused to flow in proper proportions into a centrifugal emulsifier, provided with revolving plates. The intimate mixture thus obtained is received in a lead tank, where the reaction is allowed to proceed. The oil is then washed with water in a second centrifugal emulsifier. The mixture of oil and water is then put through a separator similar to a cream-separator. Filtration of the oil through sawdust and wood-charcoal completes the process.—A. G. B.

*Manufacture of Pressure Lubricants.* A. M. Villon. Bull. Soc. Chim. 1893, **9**, 1044-1046.

THESE lubricants consist of solutions of a lime soap in a mineral oil. Several methods may be adopted for preparing them; thus, the soap may be previously prepared and then dissolved under pressure in a mineral lubricant, or the mineral and vegetable oil may be mixed and heated under pressure with lime. Magnesia is sometimes advantageously added. Good proportions are (1) mineral oil, 100 kilos.; linseed oil, 25 kilos.; earth-nut oil, 25 kilos.; lime, 6 kilos.; (2) mineral oil, 100 kilos.; linseed oil, 30 kilos.; earth-nut oil, 20 kilos.; lime, 3 kilos.; magnesia, 3 kilos.—A. G. B.

#### PATENTS.

*Improvements in or in connection with the Extraction of Oil by Volatile Solvents, and Apparatus therefor.* A. W. Macellwaine, Hull, and G. G. M. Hardingham, London. Eng. Pat. 13,478, July 11, 1893.

IN the extraction of oils from rape and other seeds by volatile solvents, a certain quantity of air, highly charged with the vapour of the solvent, escapes. The mixture of

air and vapour is passed in a finely-divided state through the seed or oil in course of extraction, which absorbs the solvent vapour. On distillation, the solvent is recovered by condensation.—J. J. K.

*An Improved Manufacture of Compounds of Iron with Fatty Acids.* A. K. Huntington, London. Eng. Pat. 14,407, July 26, 1893.

SEVEN parts of oleic acid or linoleic acid with one part of soda or its equivalent in potash, are dissolved in about 80 parts of alcohol and 20 parts of water. Also 4 parts of ferric sulphate are dissolved in 56 parts of alcohol and 28 parts of water. The two solutions are mixed, when liquid oleate or linoleate of iron containing alcohol, and an alcoholic solution of sodium sulphate, are produced. The oleate is separated by decantation, washed with alcohol, and the alcohol retained by the oleate is recovered by distillation.—J. J. K.

*An Improvement in what is commonly called Dry Soap or Soap Powder.* W. H. Horton, Old Trafford, Manchester. Eng. Pat. 8676, May 2, 1894.

THIS relates to the incorporation of disinfectants, such as carbolic acid, with the materials used in the manufacture of dry soap.—J. J. K.

##### PATENT.

*Improvements in and connected with the Treatment of Lead Sulphate for use as a Pigment.* W. V. Wilson and J. J. Lundy, London. Eng. Pat. 9521, May 12, 1893.

LEAD hydroxide is incorporated with lead sulphate to give the latter greater covering power, the proportion preferred being two equivalents of the sulphate to one of the hydroxide. The lead hydroxide may be obtained in any convenient way, but the process recommended consists in continuously heating lead carbonate in contact with water or steam. Or the lead hydroxide may be made from a portion of the lead sulphate itself; as, for instance, by treating the lead sulphate with a suitable proportion of solution of an alkaline carbonate, washing away the alkali sulphate formed, and then heating the mixture of lead sulphate and carbonate in the presence of water or steam, the process being accelerated by operating in a closed vessel under pressure.—E. S.

*Note on Gutta-percha.* — Lagarde, Annales Télégraphiques, 1893, 421. Proc. Inst. Civil Eng. 116 [ii.], 1894, 102—103.

THE gutta-percha examined by the author had been extracted from the leaves of *Isonandra* by Serullas' process. It formed the coating of a copper wire, and appeared to possess excellent insulating properties. On analysis it was found to contain 83.20 per cent. of pure gutta-percha and 16 per cent. of resins. These latter consisted of 1.72 per cent. of fluaville and 14.28 of albane, to which its excellence as a dielectric may be attributed. There was a complete absence of water, which would no doubt add to the durability of the material, while increasing its insulating power. The resins, especially albane, increase the insulation, but facilitate the ultimate deterioration of gutta-percha. Two submarine or subterranean cables made with different kinds of gutta-percha might at first possess the same properties as regards insulation; but the one containing least water and resins would remain the longest in good condition. Chemical analysis therefore affords us the only means of ascertaining whether the gutta-percha of a cable is of good or bad quality, and until recently gutta-percha of bad quality would have been accepted if it complied with the electrical conditions contained in the specification. Cases are known where the insulation of submarine cables has so deteriorated within a few months that they have become useless, and the same thing has occurred with land cables. Gutta-percha containing a large quantity of albane sometimes cracks, especially in cold weather, at places near joints. The author considers that a fairly good gutta-percha should contain at least 55 per cent. of pure gutta, not more than 5 per cent. of water, and 1 per cent. of impurities, and about the same proportion of albane as fluaville. A good material contains 60 per cent. of pure gutta, not more than 5 per cent. of water, or 0.8 per cent. of impurities, the quantity of albane not exceeding that of fluaville. A material containing 65 per cent. of pure gutta, not more than 3 per cent. of water, 0.5 per cent. of impurities, and 12 per cent. of albane, must be regarded as of very good quality.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*Tanning with Extracts.* A. M. Villon. Bull. Soc. Chim. 1893, 9—10, 1038—1044.

THE author holds that "pure" tannin will not convert hide into leather, the extractive matter always associated with the tannin in tanstuffs being essential. He distinguishes between those extractive matters which are "assimilable" in the same way as is the tannin, and those which are merely "adhesive" to the hide fibre, serving to consolidate the leather and render it waterproof (compare Procter, following abstract). If these premises be conceded, the proportion of extractive matter to tannin in a tanstuff is obviously of importance.

"Pure" tannin and an extract free from tannin, but containing the extractive matters, were prepared from oak-bark. Portions of the same hide were tanned in solutions of the pure tannin of varying strength, and in a solution of the tannin to which varying proportions of the extractive matters had been added. The conclusions drawn from the tabulated results are that—(1) pure oak tannin is absorbed in constant proportion by the hide whatever the strength of the liquor; the resulting leather is unfit for use, for it is brittle, stiff, and dry; (2) when the extractive matter is added to the liquor the yield of leather immediately increases by from 5 to 10 per cent.; (3) when the assimilable extractive matters are present to the same or to a greater extent than is the tannin, the yield is very high, but the leather is spongy,

soft, and perishable. When the proportion of assimilable extractive to tannin is 15—20:100 the leather is perfect; in this case the proportion of extractive absorbed to tannin absorbed is about 100:18, namely, the same proportion as that existing between these constituents in the oak-bark itself.

In attempting to explain the influence of the composition of a tan-stuff on its quality for producing leather, the author distinguishes between tannin, assimilable extractives, resinoid extractives, and inert extractives. A tan-stuff is the better the smaller the percentage of resinoid and inert extractives in the soluble matter of the tan-stuff, and the more nearly the proportion of assimilable matters approaches 15—18 per cent.

Extract of oak-bark is not so good as is the bark itself for tanning, and is the less so the higher the temperature at which it has been prepared; for, as will be seen in the

following table, the proportion of assimilable extractive is lowered by reason of the conversion of some of the substances contained in it into resinoid and inert extractives. Still worse is the commercial extract which is prepared with hot water and concentrated to 25° B.

The table, showing the composition of the soluble matter in the tan-stuffs, will serve to indicate which of the ordinary tan-stuffs will give a soft leather or a dry leather, when it is remembered that these qualities are dependent on the presence of a certain proportion of assimilable extractive as indicated above.

It will be noted that Valonia, divi-divi, and Kuoppenn galls approach oak-bark in that their soluble matters contain more than 12—13 per cent. of assimilable extractives, and very little resinoid extractives. Spruce, fir, pine, hemlock, alder, and mimosa barks contain sufficient assimilable extractive, but too much resinoid extractive.

—A. G. B.

*Does Tannin Tan Hides?* H. R. Procter. Chem. Zeit. 1894, 370. (Compare preceding abstract.)

In reply to the above question, the author states that there is no foundation for the assertion that pure tannin will not make leather. The only difference between a piece of a skiver tanned with pure tannin and of one tanned with sumach is in colour, that of the piece tanned with pure tannin being preferable. There is no doubt that the tannin of galls is identical with that of many other tanning materials; it is not a good tannage for sole-leather, which demands the use of tannins giving solid deposits, such as ellagic acid and phlobaphens, which impart firmness.

—A. G. B.

#### PATENTS.

*An Improved Dressing for Boots and Shoes.* T. James, Derby. Eng. Pat. 15,528, August 16, 1893.

This is a mixture of a varnish, known as body, carriage or oak varnish, with emery or other finely-divided substance. It is said to make boots waterproof, and increase their wearing qualities.—J. J. K.

*A New or Improved Material Capable of being used in Substitution for Leather and for Ordinary Paper.* N. Kumagaya, Osaka, Japan. Eng. Pat. 19,181, October 17, 1893.

See under XIX., page 751.

*A New or Improved Dubbing or Dressing for Leather.* T. W. L. Emden, London. Eng. Pat. 8695, May 2, 1891.

The essential feature of this invention consists in the use of a large quantity of mineral oil, varying from 60 to 80 per cent., in combination with about 3 per cent. of "monohydrated calcium oxide." One formula is as follows:—Mineral oil, 60 parts; vegetable oil, 20 parts; fish oil, 10 parts; water, 12 parts; monohydrated calcium oxide, 3 parts. The water and lime are put into a boiler, and the vegetable oil and 20 parts of mineral oil are added. The mixture is gradually heated to 90° C. until saponification takes place; the remainder of the mineral oil and the fish oil are then added, and the mixture allowed to cool.

—J. J. K.

## XV.—MANURES, Etc.

## PATENTS.

*Improvements in the Manufacture of Manures, and New Processes for obtaining the same.* H. E. Newton, London. From C. Seybold and F. Heeder, Wirlfrath, Elberfeld. Eng. Pat. 11,804, June 15, 1893.

Phosphatic raw materials heated at 50–120° C. in an atmosphere of moist carbonic acid are decomposed according to the equation—

1st stage—

2nd stage—

By the addition of alkaline carbonates the double salts  $(\text{PO}_4)_2, \text{Ca}_2\text{HK}$  and  $(\text{PO}_4)_2, \text{CaH}_2\text{K}_2$  may be similarly prepared.

The conversion takes from 12 to 24 hours, according to the nature of the raw material and the conditions of treatment, which are suitably varied.—C. F. C.

*New Process for the Preparation of Bi-calcic Phosphate soluble in Ammonium Citrate.* T. Chandelon, Liège. Eng. Pat. 13,842, July 17, 1893.

Raw calcium phosphate is treated with dilute sulphuric acid (15–25 per cent.  $\text{H}_2\text{SO}_4$ ), and the resulting solution, containing 7–12 per cent.  $\text{P}_2\text{O}_5$ , is cooled and neutralised with a cooled lime water. Reaction at 0° C. results in the precipitation of the hydrate  $\text{Ca}_2\text{H}_2\text{P}_2\text{O}_7 \cdot 2\text{N}_2\text{O}$ , entirely soluble in ammonium citrate.

A simple form of apparatus is figured for carrying out the reaction under the essential condition of low temperature specified.

This condition constitutes the patentee's claim.—C. F. C.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Loss of Heat in the Steam Engines of a Sugar Factory.* Classen. Zeits. Ver. Rübenzuck.-ind. 44, 80.

To elucidate this question, the author has carried out a series of practical experiments in a beetroot factory, the normal working capacity of which was equal to 7,000–7,500 metre-centners. This factory possessed 17 old non-expansive steam engines, which required 35 kilos. of steam per horse-power per hour. As a mean deduced from a large number of determinations, he finds that the loss of heat corresponds to 16.4 per cent. of the steam required, a value which agrees with that calculated from exact data, thus:—By condensing in the pipes, 5.83 per cent.; by condensing in the cylinders, 1.38 per cent.; by friction of the machinery and by expansion of steam, 4.58 per cent.; giving a total loss of 14.58 per cent.

On economical grounds the author denounces the complete centralisation of the steam engines, the substitution of non-expansive for expansive engines, and the erection of evaporators having a higher than quintuple effect. It is urged that the steam pipes should be simplified as much as possible and well covered, the latter especially in the case of recent plant. Moderate centralisation of the machinery is to be recommended in such a way that the waste steam can be utilised as far as possible.—A. R. L.

*The Multirotation of Sugars.* P. Th. Muller. Comptes rend. 1894, 118, 425–428.

Most sugars exhibit a peculiar phenomenon in aqueous solution: the rotatory power of the substance when dissolved in water varies with the time, and to this phenomenon the name multirotation is given. If the temperature be kept constant, the rotatory power has a certain value immediately after the sugar is dissolved; and this value generally diminishes, more or less quickly, but as a rule attains a constant value in about twenty-four hours. Although the cause of this multirotation remains unknown, we can investigate the variation of the rotation, and find the law which it follows by assuming that during the whole duration of the phenomenon we have present two modifications of the particular sugar, each of which modification possesses a definite specific rotation. This assumption does not premise anything respecting the nature of the modifications—whether the substance retains for a time in solution a certain crystalline structure, whether a gradual process of hydration of the molecules goes on, &c. As the unstable modification A becomes transformed into the stable modification B, the rotation itself will vary. Let  $\rho$  be the specific rotatory power of B,  $\alpha$   $\rho$  the specific rotatory power of A, each referred to the anhydrous substance; suppose that we have  $p$  grms. of substance dissolved in  $V$  cubic centimetres; that we observe the rotation in a tube  $l$  decimetres long; and that the angle of rotation at the time  $\theta$  (counting from the time of solution) is  $\alpha$ . If  $x$  is the mass of A, and  $y$  the mass of B at the time  $\theta$ , we have—

$$\alpha = \frac{a \rho x l}{V} + \frac{\rho y l}{V},$$

$$\text{and } x + y = p.$$

If the final angle of rotation is  $\alpha_n$ , we have—

$$\alpha_n = \frac{\rho p l}{V},$$

$$\text{and } \therefore \frac{(\alpha - 1)x}{p} = \frac{\alpha}{\alpha_n} - 1,$$

an equation which gives the value of  $x$  (the amount of the unstable modification) at the time  $\theta$ . Now, it is natural to assume that the quantity  $dx$  which is transformed during the infinitely short time  $d\theta$  is proportional to the mass  $x$  still remaining at the time  $\theta$ .

$$\text{Thus } dx = -Cx d\theta$$

From this, by integrating, and replacing Napierian by common logarithms, we get—

$$C = \frac{1}{\theta - \theta_0} \log \frac{\alpha - \alpha_n}{\alpha - \alpha_n}$$

where  $\alpha$  is the rotation at the time  $\theta_0$ .

Experiment shows that such a constant ( $C$ ) really exists; thus confirming the above hypotheses and deductions. Pareus and Tollens have studied the rotatory power of sugars during the first few hours after solution, and the author has made use of their curves and tables in testing his theory. From one set of experiments on arabinose (at 20°) he finds 0.0301 as the value of the constant  $C$ ; another set of experiments gives the value 0.0293. The value of the constant for xylose is 0.0201; for rhamnose, 0.0393; fructose, 0.0202; galactose, 0.00927; milk-sugar, 0.00405; maltose, 0.00524; and for glucose about 0.00365. Thus the reaction which takes place during the period of multirotation is of the first order; it follows the law of active masses. The constant  $C$ , at any given temperature, measures the rate of progress of the phenomenon. This rate is much more rapid in the case of the pentoses than in the case of the other sugars (hexoses and polysaccharides).

—D. E. J.

*Diffusion.* Gaz. cukr. 1, 386.

At the meeting representative of the Polish Sugar Industry, a committee was appointed to investigate the influence of the form of the diffusors and the number of vessels in the diffusion battery on the entire diffusion process and more especially on the purity of the juice.

The following is a summary of the report of B. Broniewski, whose experiments were conducted in two factories; one at Krasiniec and the other at Sanniki. The diffusers in the former factory are 1.5 metres in diameter and 2 metres in height, whilst those in the latter factory are barely 1 metre in diameter and are 2.1 metres in height. The experiments confirm Herzfeld's observation that the purity of the juice is the higher the thinner the slices of roots employed. If, however, thin slices of roots are used, the pressure falls in a battery consisting of several high and narrow diffusers, because of the considerable velocity with which the juice runs through, so that the number of vessels in the battery must be diminished. This may, however, not deleteriously, for it causes an increase in volume of the juice, or less perfect edulcoration. In working therefore with thin slices, it is advisable to employ lower and wider vessels. Regarding the number of vessels, the experiments show that a battery consisting of few members and a short diffusion period is to be recommended; in this way the purity of the juice is enhanced. The number of diffusers is so regulated that with 100 per cent. juice extracted sufficient lixiviation is attained.

No special experiments were made to ascertain the speed at which the juice should run through the diffusers. In Sanniki the highest purity is 30 per cent. with a speed of 7 mm. per second.—A. R. L.

#### *Combustible Gases arising from the Diffusion Battery.* Dewald. Deutsch. Zuckerind. 19, 52.

THE evolution of combustible gases from the diffusion batteries is not due, as Stohmann believes, to the action of the acid juice on the iron of which the apparatus is constructed, but is to be ascribed (as already observed by Scheibler) to a lactic or butyric fermentation. The prescribed addition of lime tends therefore to increase rather than eradicate the evil, because these fermentations proceed more vigorously in alkaline solutions. The ferments are derived from the damp soil adhering to the roots, a fact which has been proved experimentally by the author. Portions of this soil were added to a solution of sugar, made alkaline with lime at 35°–40° C., when brisk butyric fermentation set in, much hydrogen and carbonic acid being evolved. The combustible gases arising from the diffusion batteries contained 30–70 per cent. of carbonic acid and 20–35 per cent. of hydrogen. The addition of phenol or of ammonium fluoride was of no avail, but sterilisation was accomplished by raising the temperature to 78° C. or above.—A. R. L.

#### *Filtration of Diffusion Juice after Heating.* Gaz. cukr. 1, 190.

THIS process having been carried out in a certain sugar factory, it is found that the difference in the purity-quotient of the juice before and after filtration never exceeds 0.26. It is probable, however, that the filtration exerts a favourable influence on the final product, inasmuch as a certain amount of melassigenic proteid substance is removed by it. Double filtration, before and after the heating, is still more serviceable; in this way the incrustation of the walls and steam pipes of the heating vessels by impurities is prevented and the heating effect increased.—A. R. L.

#### *Purification of Diffusion Juice.* C. Liedtke. Gaz. cukr. 1, 237.

WHEN diffusion juice is not previously warmed, it filters with extreme slowness, so that a great filtering surface is necessary, and being thus exposed to the air may become acid and ferment. The author proposes to add defecation mud to the diffusion juice to impart a certain alkalinity to it. Various quantities from 0.5 to 3.5 per cent. of defecation mud were added to the juice, which was filtered direct at a temperature of 44° C. and also at 75° C. In the former case filtration proceeded slowly, in the latter fairly quickly; in both cases the filtered juice was sparkling and

did not undergo change when exposed to the air. The purity quotient rose 2–3 per cent. Diffusion juice treated in this way contains little proteid matter and pulp, and saturates more quickly. After the first saturation it yields as pure a liquor as can be obtained by filtering thin liquor over animal charcoal.—A. R. L.

#### *Rate of Filtration of Solutions of Sugar.* Brendel. Zeit. Ver. Rubenzuck.ind. 43, 1088.

THE author's experiments were made with filter paper, using a 60 per cent. solution of pure saccharose. He finds that the rate of filtration increases with the temperature, the increase being the greatest between 0 and 30° C., a fact of considerable importance in carrying out Soxhlet's process of refining.—A. R. L.

#### *Precipitates formed during the Heating of Beet Juice.* A. Herzfeld. Zeit. Ver. Rubenzuck.ind. 43, 1065.

THE author has previously observed (this Journal 1893, 1065) that the precipitates which form on heating crude diffusion juice contain from 10 to 20 per cent. (on the dry substance) of proteids. He now recognises the presence of large quantities of pectous substances, fatty acids, oxalic acid, lime, and magnesia. Phosphoric acid is perhaps also an occasional constituent. No optically active compounds could be detected in the precipitates; it is pointed out, however, that such substances may have been originally present.—A. R. L.

#### *Recovery of Nitrates in Sugar Factories.* Gaz. cukr. 1, 125.

IX Tschernigoff the soil is very rich in salts, especially nitrates, and the beetroots grown there assimilate the latter, which in the course of manufacture passes into the juice. A rainy season tends to increase the quantity of nitrates in the roots. The nitrates remain unaltered during the process of manufacture and occur in the massecuite. Such a massecuite, containing nitrates, does not differ in appearance from an ordinary massecuite. In order to free the sugar from nitrate, the massecuite is covered cold in the centrifugal; that is, very little steam is employed, so that the nitrates, being the more readily soluble, pass into the syrup, and the sugar remains pure enough to be sold to refiners. The nitrates are similarly removed from the after-products. In most factories nitrates occur in the molasses, which latter are sold very cheaply. In order to obtain nitrates from the third product, which is sometimes done, this is dissolved in lukewarm water to a density of 4° Baumé, the solution heated to 60°–70° C., rapidly transferred into flat receptacles, where it is kept for 8–10 days at a temperature of 2–3° C. or –2 to –3° C. A mixture of sodium and potassium nitrates deposits, whilst the supernatant liquor which still contains nitrates is again subjected to the same process.—A. R. L.

#### *Mucilaginous Beet Juice.* Anderlik. Zeit. Zuckerind. Bohm. 13, 190.

THE cause of the juice becoming mucilaginous is a kind of fermentation, the products of which are dextrose, mannitol, non-volatile acids, and carbonic acid. There are also formed organic substances not precipitable by basic lead acetate; these latter may be identical with those occurring in decomposed beetroots.—A. R. L.

#### *Continuous Saturation.* Roboux. Sucri. indigène, 43, 179.

FOR successfully conducting this process, it is necessary to charge the apparatus with a certain maximum of juice at a temperature of 80° C., and to employ gas containing 30 per cent. of CO<sub>2</sub> or preferably a higher percentage. For simplicity, speed, and cleanliness the process is said to surpass all others.—A. R. L.

*Precipitates obtained in the Evaporating Apparatus used for Cane Sugar Juice.* Shorey. *Sugar Cane*, 26, 67.

The author finds that the above-mentioned precipitates often contain considerable quantities of citric acid, which fact is noteworthy inasmuch as Prinzen-Geerlings has not detected this acid among the products of the manufacture of sugar in Java.—A. R. L.

*Control of Beetroot-Sugar Manufacture.* Battüt. *Bull. l'Ass. des Chim.* 11, 478.

The control of the working of a beetroot-sugar factory as it is at present conducted is, according to the author, insufficient. The following important facts are left unexplained and completely ignored:—The amounts of sugar found in the diffusion juice, exhausted beetroot slices, and waste waters are generally far below that found in the roots themselves; whilst the amount of sugar found in the massecuite and defecation mud is below that found in the diffusion juice. The lime and pectous substances may, at all events, play a decided role here.—A. R. L.

*The Manufacture of Potato Starch by the Continual-Flow System.* Boudonneau. *Bull. Soc. d'Encouragement*, 1893, 849—851.

Most potato starch manufactories produce, apart from first-quality starch, considerable quantities of an inferior (coloured) grade, the necessity for so doing arising in great measure from the faulty process employed. Coloration of the starch is due to various causes, first and foremost being the ready decomposition of the pectous bodies existing in the potato-juice into gelatinous products in which the starch and pulp become entangled, forming greasy masses that are very liable to lactic and butyric fermentation. Another factor is the nature of the water used. The lime salts in the latter react with the soluble phosphates of the juice, forming a deeply-coloured and very light precipitate of calcium phosphate. It is well, therefore, to employ the softest water obtainable.

In the majority of cases the process of purification adopted consists in allowing a dilute mixture of the crude starch with water to settle in tanks, the operation being repeated several times. The separation thus effected is, however, by no means complete. Only the lower portion of the deposit consists of pure starch; the middle portion is contaminated with coarse fibrous matters, removable, however, by means of sieves; whilst the upper layer consists of small starch granules and all the finer impurities, and when worked up, only yields an inferior grade of starch. The production of "seconds" may be entirely avoided, however, by a process employed at Chalons-sur-Saône. Instead of settling tanks, a trough is used, 35—40 m. long, 1.5 to 2 m. wide, and 35—60 cm. deep, constructed of masonry, or preferably of wood lined with zinc. Along this trough, the cream of starch is caused to flow continuously in a layer 4—5 cm. deep, and at a rate not less than 5 m. per minute. Under these circumstances, the starch settles with great compactness, and so rapidly, that by the time the stream has reached the end of the trough, very little is left in suspension. On the other hand, the impurities, being lighter, have not time to settle and are swept on by the current. The deposit obtained, when submitted to a second similar treatment, yields perfectly pure starch. The advantages of the process are—

1. Rapid separation of the starch without prolonged contact with water.
2. Nearly the whole of the starch is obtained in the form of "extra superior" quality.
3. The necessity of working up inferior grades disappears.

—H. T. P.

*Compounds of the Sugars with Polyhydric Phenols.* E. Fischer and W. L. Jennings. *Ber.* 27, 1355.

See under XXIII., page 765.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*The Formation of Cane Sugar during the Germination of Barley and during the Ripening of the Apple.* L. Lindet. *Bull. Soc. Chim.* 1894, 11, 18—21.

DURING the germination of barley, the cane sugar it contains gradually increases in amount and the starch simultaneously decreases. Apples, during the ripening process, become richer in cane sugar and invert sugar, also with a simultaneous decrease in the amount of starch. The same occurs during the artificial ripening produced by storing. When the starch is reduced to less than about 2 per cent. the percentage of cane sugar diminishes, while that of the invert sugar increases.—J. G. W.

*The Formation of Mannite in Wines.* H. and A. Malbot. *Bull. Soc. Chim.* 1894, 11, 87—89, 176—179, and 413—415.

The presence of mannite in wines—at first taken as a proof of adulteration and afterwards as only occurring in sour or diseased wines—has for some time been recognised as occurring in thoroughly sound wine, and can in no wise be looked upon as a sign of disease or non-keeping power in a wine. Various hypotheses as to its formation, have been put forward, but none of them cover all the cases in which it has been found. The author has obtained mannite in a wine made by very regular fermentation at 24°, the mannite appearing some time after fermentation had ceased. All the glucose had previously disappeared, but a not directly fermentable carbohydrate was still found, and the mannite was apparently derived from this. In another wine which contained the same carbohydrate, but which was highly sulphited, no mannite was formed. The author believes that strong fumigation or sulphiting will prevent the formation of mannite, if such formation is considered undesirable.—L. T. T.

*Diseases of Wine.* Kayser. *Bull. Soc. d'Encouragement*, 1894, 97—99.

THE ferments causing disease in wine may be classed under two heads, aerobic and anaerobic organisms.

*Aerobic ferments.*—*Mycoderma vini*.—This ferment chiefly attacks new wines, and is readily combated by excluding air from the casks. *M. aceti* favours thin, dry wines, converting their alcohol into acetic acid. Here also exclusion of air is the best preventive.

*Anaerobic ferments.*—The *viscous ferment* generally attacks new white wines containing but little alcohol. It forms chaplets of spherical cells imbedded in a gelatinous matrix. Tannin appears to check its growth, but wine when once affected by it never regains its original flavour and bouquet. The ferment of *bitter* ("amers") wines is found usually in old Burgundian wines. The wine becomes insipid, bitter, and somewhat sharp, and deposits a voluminous coloured sediment consisting of extremely thin immobile rods. According to Pasteur and Duclaux it converts the glycerin into acid.

The ferment producing effervescence (*vins poussés*) may occur in all species of wines, and is favoured by high temperatures. The wine becomes turbid and develops considerable pressure owing to the production of carbonic acid. The ferment occurs in tangled masses of thin filaments, and appears to grow at the expense of the calcium tartrate, which it converts in volatile acids.

The turned ("tourné") wine ferment resembles the preceding, except that it does not produce carbonic acid. It attacks the tannin and tartaric acid of the wine, the products formed being acetic, tartronic, and lactic acids.

The *mannite* ferment occurs only in imperfectly fermented wines when the temperature rises too high in the tuns (40°—55° C.). The consequent enfeeblement of the yeast allows the mannite ferment to act, which it does at the expense of the levulose present, the principal product being mannite, and to a smaller degree fixed and volatile acids.

As regards the general precautions to be adopted in the manufacture of wines, it is of importance to perform the operations of racking and priming at the right time. An infallible preventive, however, consists in heating the wine to 55° C. (pasteurisation).—H. T. P.

*The Chemical Properties of the Alcoholic Extract of Beer-yeast.* J. de Rey-Pailhade. *Comptes rend.* **113** (1894), 201—203.

The chemical phenomena produced in living organisms are caused by proximate principles (*principes immédiats*), generally unstable, which are often destroyed by the action of the solvents used to extract them. It is nevertheless possible, by the aid of low temperatures and certain feeble antiseptics, to obtain solutions which, although deprived of every organised element, produce chemical phenomena characteristic of life. Such a solution may be prepared by mixing 100 grms. of fresh pressed beer-yeast with 55 grms. of water containing a little glucose, and then adding gradually 45 grms. of 90 per cent. alcohol. The mixture is kept corked up in a flask at a temperature of 0 for three days and then filtered. The filtrate is sterilised according to d'Arsonval's method, and is placed in an exhausted receiver to remove excess of dissolved carbonic acid. It is slightly acid, and although it is deprived of all living organisms, it possesses the following chemical properties, which also belong to living yeast:—It produces sulphuretted hydrogen on contact with sulphur in the cold; in the absence of oxygen it spontaneously sets free carbonic acid; and it absorbs oxygen from the air.

Spallanzani showed that tissues recently detached from the living organism absorb oxygen and produce carbonic acid. Some years ago the author showed that tissues when pounded with sulphur produce sulphuretted hydrogen. His present researches show that the proximate principles themselves produce these phenomena when they have been extracted by suitable solvents, and that these effects appear to be independent of any organised element.—D. E. J.

#### PATENTS.

*An Improved Distilling Apparatus.* A. Lavy, Paris, France. Eng. Pat. 12,528, June 26, 1893.

THE apparatus comprises an ordinary boiler and a dome-shaped rectifier firmly attached to the top of the latter. The rectifier is divided by horizontal partitions into a series of chambers, each one of which is again separated into two

compartments by an intermediate corrugated partition. The wine, &c., to be distilled circulates through the outer pipe of a double coil arranged round the outside of the dome, and is discharged into the upper half of the first chamber, from whence it flows by an overflow pipe to the upper division of the second, and so on, finding its way at length into the boiler. The alcoholic vapour rises through a central pipe, which connects together the lower portions of all the chambers and finally passes into the inner tube of the coil mentioned above, where it is condensed. It will be seen that the use of cooling water may be entirely dispensed with, the wine itself being made to do the work of condensation. The apparatus is adapted for continuous distillation, and is claimed to yield rectified brandy at one operation.—H. T. P.

*Improvements in and Apparatus for Sterilising or Preventing Fermentation or Acidification of Beers, Beverages, or the like.* P. W. May and R. E. R. Newlands, London. Eng. Pat. 12,609, June 27, 1893.

THE beer or other liquid, previously aerated or charged with carbonic acid, and contained in stoppered bottles or other vessels, is gradually heated to the requisite temperature in a strong water-bath provided with an air-tight cover, and again slowly cooled. Heating may be effected by any of the usual means, and during the operation a considerable pressure is maintained in the water-bath to counteract the internal pressure in the bottles, &c., and prevent their rupture.—H. T. P.

*New or Improved Process and Apparatus for Purifying Liquids.* L. Wagner and J. Marr, Baltimore, Maryland, U.S.A. Eng. Pat. 7027, April 9, 1894.

THE object of this invention is to destroy and remove the organisms from liquids and beverages, such as beer, wine, water, &c. For this purpose a process of electrolysis and filtration is resorted to. The apparatus employed consists of a covered cylindrical outer vessel, inside which a drum constructed of perforated sheet metal covered with wire gauze, and capable of being rotated on its axis, is supported on a vertical shaft. In operation, the liquid to be purified is discharged into the drum, the latter being rotated at a high speed (1,000 revolutions), and submitted to the action of an electric current supplied through carbon electrodes suspended near the bottom of the drum by means of rods attached to the cover of the apparatus. The liquid, passing through the walls of the drum, filters through a filter-bed composed of fragments of sponge clamped between metal plates, situated at the lower part of the outer vessel. During the process, air, sterilised by passage through a furnace, and subsequently cooled and filtered through cotton wool, &c., is supplied to the apparatus.—H. T. P.

*Improvements in the Manufacture of Spirits, and in Apparatus for that Purpose.* J. J. Murphy, Cork. Eng. Pat. 7858, April 20, 1894.

IN order to prevent the excessive production of fusel oil and other by-products during fermentation, the temperature of the liquid in the vats is not allowed to rise above 72° F., attenuating coils being used to regulate the heat if necessary. An aerating device is also provided in the shape of a pipe perforated with holes, placed near the bottom of the vat, by means of which air may be pumped through the liquid.—H. T. P.

# XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY AND WATER PURIFICATION, DISINFECTANTS.

## (A.)—CHEMISTRY OF FOODS.

*Estimation of Fat in Cheese.* S. Bondzynski. *Zeits. anal. Chem.* **33**, 186.

See under XXIII., page 766.

*Drinking-Water obtained from Artesian Wells at Mantua.* P. Bonato. *Annali della Soc. degli Ing. e degli Arch. Ital.* 1893, 399. *Proc. Inst. Civil Eng.* **116**, 1894, 34—35.

MANTUA, a town of 30,000 inhabitants, formerly derived its entire water-supply from surface-wells, vitiated by the contents of the innumerable cesspools necessitated by the absence of any systematic collection and disposal of sewage. To amend this, after consideration of various sources of supply, it was decided to sink a number of artesian wells. The first instalment of the work comprised four such wells, which were sunk to the respective depths of 398 ft. 6 in., 398 ft., 351 ft., and 382 ft. 6 in. From these an excellent supply, at the rate of 28.6 gallons each per minute, was delivered to a height of 13 ft. 3 in. above the street datum level. Following this, ten other wells were sunk, the average delivery being as follows:—

Height above Datum in Feet.	Delivery in Gallons per Minute.
2' 62	41' 0
6' 24	35' 2
9' 52	26' 4
12' 78	14' 3
16' 06	1' 5
16' 49	"

The total supply is equivalent to an allowance of 14.3 gallons per head. Each well cost 300*l.*, the total work therefore being carried out for 4,200*l.*

The tubes are of mild steel,  $3\frac{1}{2}$  in. external diameter, 0.35 in. thickness of metal, in length varying from 7 ft. 3 in. to 19 ft. 6 in., screwed together, and sunk by an 8-cwt. steam-hammer, with a fall of 2 ft. 6 in. at 39 blows per minute. Each tube was sunk in from 20 to 30 days. The water was submitted to severe chemical and bacteriological analysis. It is perfectly clear, and has an average temperature of 58.7° F. At first there is a slightly perceptible but very transient sulphurous odour. The water contains, however, not the slightest trace of sulphuretted hydrogen, and it is considered probable that the peculiarity is simply the effect of the contact of the water with the steel tube, the pressure at the bottom being equal to 176 lb. per sq. in.

## PATENTS.

*Improvements in the Preparation and Treatment of Animal and Vegetable Substances and Fruit, and Compounding the same with other Ingredients for Use as Human Food.* L. C. Tipper, Yardley, Worcester. Eng. Pat. 13,600, July 13, 1893.

CHOPPED meat, either raw or cooked, is appropriately seasoned, mixed with flour or other farinaceous material, and made into a dough with new milk, to which there has been added gelatin containing borax (3 ounces of gelatin, 1 ounce of borax to 12 gallons of new milk for 500 lb. of meat and

flour). The mass is rolled into sheets, made into biscuits, dried, baked, and coated with gelatin, or gelatin and borax, to preserve them from the air.

Fish, vegetables, cheese, and fruit may be similarly treated.—A. G. B.

*Improvements in and relating to the Manufacture of Food for Horses.* H. H. Lake, London. Eng. Pat. 13,704, July 14, 1893.

The food is composed of blood, extract of meat, and Iceland moss. For the last named, chaff or chopped straw, treated as described for the Iceland moss, may be substituted.

The blood is from healthy oxen; it is strained, mixed with 2 per cent. of pure pepsin, and 0.1 per cent. of pure dilute hydrochloric acid; the mixture is kept at 37° C. for eight hours, being repeatedly stirred during this time.

The meat is freed from fat and bone, and is thoroughly beaten with a heavy hammer on a hard wooden block. One part by weight of the mass of meat is placed in twice its weight of water, together with 3 per cent. of its weight of dried melon leaves, and 0.1 per cent. of its weight of hydrochloric acid. After eight hours, the steeped meat is gradually heated in a boiler to a "boiling heat," the process preferably lasting eight hours, the boiling proper being continued for half an hour. The extract of meat thus produced is filtered.

Three kilos. of the washed Iceland moss are steeped in 70 litres of water, containing 180 grms. of potash, for 24 hours, being repeatedly stirred. The colouring matter and bitter principle of the Iceland moss having been thus extracted, the moss is washed and spread on boards to dry.

Two parts of the blood are mixed with one part of the extract of meat, and one kilo. of the Iceland moss is added to three litres of the mixture. When the moss is completely saturated, it is spread on boards and dried for 12—14 hours in a drying chamber. It is then sufficiently brittle to be ground to a fine powder, which is mixed with moistened oats, bran, or other usual food for horses. The condition of horses is stated to be much improved by this food.

—A. G. B.

*Improved Baking Powder.* W. Brothers, Rawtenstall, Lancaster. Eng. Pat. 16,458, September 1, 1893.

AMMONIUM hydrogen carbonate is reduced to a fine powder and mixed with some inert material, such as rice-flour or similar substance, to increase its bulk.—A. G. B.

*An Improved Composition for Use as Food, and Method of Preparing the same.* E. O. Taffin, Stockholm, Sweden. Eng. Pat. 7543, April 16, 1894.

HEMP-SEED extract is mixed with malt and malt extract, cacao-powder being added if it be desirable that the compound should taste of cacao. The hemp-seed extract is obtained by the use of petroleum ether. The malt for the preparation of this food must be dried at a low temperature (50°—60° C.), and the brining and malting must continue during a longer time than is the case in common malt preparation. Wheat and Indian corn are the most convenient kinds of corn. Only part of the malt is mashed and treated with hot water; the solution is evaporated to a syrup. Another part of the malt is ground to meal. The hemp-seed extract and the malt extract (equal parts, for instance) are mixed, and so much malt-meal is added that the whole obtains the consistency of dough; the mass is pressed into cakes and dried; these cakes are easily ground to meal. The cacao-powder is incorporated together with the malt-meal. Cacao-powder may entirely replace the malt-meal. The proportions are varied, according to the taste required; if the bitterness of the hemp-seed extract is to be entirely masked, the proportion of this extract to the malt extract should be 1:4. The food is a suitable substitute for tea and coffee, and is prepared in the same manner as ordinary cacao is prepared.—A. G. B.

## (B.)—SANITARY CHEMISTRY AND WATER PURIFICATION.

*Hydrogen Dioxide in Atmospheric Air and in Aqueous Deposits therefrom.* I. v. N. Hlosva. Ber. 1894, 27, 920—925.

In this paper the author answers the criticism which Schöne has recently passed (Ber. 1893, 26, 3011) upon his (the author's) work which was performed in 1889 (Bull. Soc. Chim. 2, 347, &c.). This work showed that an attitude of suspended judgment is necessary with respect to the assertion that air, rain, and dew contain hydrogen dioxide and ozone.

As reagents for ozone the author used thallous hydroxide and  $\alpha$ -azomethylamine benzene-sulphonie acid, both of which are perfectly trustworthy under the prescribed conditions. Reliance must not be placed on a mixture of potassium iodide, starch, and ferrous sulphate as a test for hydrogen dioxide. Titanic acid in strong sulphuric acid is the most characteristic reagent for hydrogen dioxide, and chromic acid with ether holds the second place; if these reagents will not detect hydrogen dioxide in rain water it must be concluded that the quantity present is below the limit of sensitiveness. There is an oxidising agent present in rain which, whatever its precise nature may be, behaves ultimately as nitrous acid, and liberates iodine from potassium iodide even in the presence of starch.

Schöne himself draws attention to the unreliability of the guaiacum-diastase reaction in the presence of ammonia—another reason for rejecting the evidence of this reagent, since the role of the ammonium hydrogen carbonate in rain water with respect to the reagent, is not known.

There is no doubt but that air contains nitric peroxide as a constant constituent, probably formed during combustion. If a 1 per cent. solution of pure potassium iodide be exposed to the air, even in the dark, iodine will be detected therein by starch after a time; and by warming the liquid until the blue has disappeared, and applying Griess' reagent, nitrous acid will be found to be present. (The starch gave no reaction with Griess' reagent, nor could any sulphur dioxide be detected in the air.) Does not this prove the presence of nitrous acid in the air? Even supposing that the air contains its nitrous acid only as ammonium nitrite, as Schöne contends, there is no reason to suppose that this will not eventually liberate iodine from potassium iodide. When, to a solution of potassium iodide and potassium nitrite, carbon dioxide solution is added, iodine will be liberated, and can be detected by starch; in this way <sup>TABLEAU</sup> part of nitrous acid will be detected in the course of 60—80 minutes. It is hardly surprising, then, that Schöne should obtain such a reaction in rain water, which avowedly contains ammonium nitrite, in the course of 6—8 hours.

That there is an oxidising agent in the air, apart from the oxygen, no one denies, but heretofore the action of nitric peroxide has been overlooked, and, unless it be first removed, the presence of ozone and hydrogen dioxide cannot be affirmed. The author used a 4 per cent. solution of sodium hydroxide for removing the nitrous acid: in such a solution, if free from nitrite, hydrogen dioxide in small quantity does not decompose, even after days, and may be recovered by distillation. Therefore, the contention that if the hydrogen dioxide in the air be in excess of the nitric peroxide it should be possible to detect it in the caustic soda solution, is valid. Obviously, to look for hydrogen dioxide in rain water in which nitrites can be detected is absurd.

It is not necessary to suppose that because nitrate as well as nitrite is found in the dilute caustic soda through which air is passed, the nitrite has been oxidised by ozone or hydrogen dioxide in the air. It is well known that nitric peroxide in presence of oxygen and water is largely converted into nitric acid. Moreover, a dilute potassium nitrite solution containing nitric peroxide will certainly no nitrite after a month.

To render his 1 per cent. solution of potassium iodide more sensitive to ozone, the author provided for the potassium hydroxide which would be liberated, by the addition of sufficient phosphoric acid to change litmus

paper feebly red. When air, freed from nitrogen oxides, is passed through such a dilute solution of hydriodic acid, iodine is not liberated even after weeks.

The statement that atmospheric ozone is more abundant in summer is curiously in accord with the fact that nitric peroxide is more abundant during the summer months.

—A. G. B.

*On the Question of Atmospheric Hydrogen Dioxide.*

E. Schöne. Ber. 1889, 27, 1233—1235.

This paper is a reply to Hlosva (see preceding abstract). The real basis of the dispute is the question whether a mixture of potassium iodide, ferrous sulphate, and starch, and a mixture of guaiacum and diastase are characteristic reagents for hydrogen dioxide or not. Hlosva is in error when he states that oxides of nitrogen or neutral nitrites give the same reactions as are given by hydrogen dioxide. It is by no means easy to refute Hlosva's statements, but the author claims this has been done in a paper published at the beginning of the year (Zeits. Anal. Chem. 1894, 33, 137). In the same paper it is also shown that thallous hydroxide is not a perfectly trustworthy reagent for ozone, and that carbon dioxide in the presence of ammonium nitrite cannot give a reaction with potassium iodide, in presence of ferrous sulphate and of starch, which can be mistaken for that of hydrogen dioxide.—A. G. B.

*The Electrical Purification of Sewage on the "Hermite" System.* Georges Vitoux. La Revue Techn. 1894, 106. Proc. Inst. Civil Eng. 113, 1894, 39—40.

An account is given of a small plant erected at the Figaro offices in Paris for the trial of this process, which is already in successful operation at Brest and other towns in France, and at Worthing in this country. A current of electricity is employed to decompose an aqueous solution of certain soluble chlorides, preferably magnesium chloride, or as mixture of this salt with sodium chloride in the proportion found in sea-water or in salt-lye. By this means, at the positive extremity a very unstable compound of oxygen and chlorine is produced, which possesses powerful oxidising properties, while at the other pole an oxide is formed which is capable of precipitating the various organic substances present in sewage-water. It thus becomes possible to destroy entirely the products of putrefaction, together with the foul gases, such as the sulphuretted and carburetted hydrogen, as also the germs and microbes which may be present, while, owing to the precipitation which takes place of the albumenoid matters, the foul liquid is immediately clarified. The disinfecting liquid, as fast as it is prepared, is pumped up from the central producing-station to the closet basins or other places when it has to be used, having therefore the freshly-formed chemical compounds in the nascent state, and capable at once of attacking the various impurities. This latter apparatus consists of a vessel constructed of galvanised east-iron, having in the lower part of it a tube perforated with a number of holes and furnished with a zinc tap. The sea-water or other solution of chlorides enters through this tube. In the upper part of the vessel, also formed of galvanised east-iron, and widened out to serve as a trough or channel for the decomposed liquid, which rises to this point, is a pipe through which this liquid is drawn off for use, and thus a constant circulation of the contents is effected. The negative electrodes consist of a number of zinc discs, mounted on two horizontal shafts passing through the lower part of the vessel, which shafts are caused to revolve slowly. Between each pair of zinc discs are placed the positive electrodes, the active surfaces of which consist of sheets of platinum-gauze, held in position by a framework of ebonite, which ensures the necessary rigidity. The upper part of the gauze is soldered to a plate of lead, which is perfectly isolated. Every positive electrode communicates by means of the lead with a copper rod traversing the electrolyser, and contact is made by a screw nut. The copper bar which carries the positive electrodes communicates with the positive pole of the dynamo. The current is conveyed to each of the platinum

electrodes and passes thence, through the liquid to the zinc discs, serving as the negative electrodes: these are in contact, through the iron containing-vessel, with the negative pole of the dynamo. Arrangements are made for the mechanical cleaning of the zinc discs. Currents are employed of from 1,000 to 1,200 amperes. The liquid, as it issues from the electrolyser, has a faint odour of chlorine and is ready for immediate use. For this purpose it may be pumped from the central station to the points where it is required.

#### PATENT.

*New or Improved Process and Apparatus for Purifying Liquids.* L. Wagner and J. Marr, Baltimore, Maryland, U.S.A. Eng. Pat. 7027, April 9, 1894.

See under XVII., page 751.

#### (C).—DISINFECTANTS.

*The Disinfecting Power of Soap Solutions in respect of Cholera Germs.* Maximilian Jolles. Zeits. für Hygiene, 1893, 460. Proc. Inst. Civil Eng. 116, 1894 [ii.], 48—49.

To determine the value of soap-solutions in the disinfection of materials containing the germs of cholera, five different sets of experiments were undertaken with each of the following kinds of soap, viz., potash washing-soap, potash lysol-soap, glycerin-soap, Leda toilet-soap, and shaving-soap. Detailed analyses are given of each of these substances, the total alkalis in which varied from 10.4 to 7.3, while they contained from 0.009 to 0.065 per cent. of free alkali. In the original series, each solution was tested at 10 different degrees of strength, from 1 up to 10 per cent. In carrying out the tests 100 cub. cm. of soap solutions were introduced into sterilised Erlenmeyer flasks provided with cotton-wool stoppers. These flasks, with contents, were exposed on three separate days for half an hour each day to the action of the Koch steam-bath and cooled down to 15° C. A 10 per cent. meat-juice bouillon, infected with cholera bacteria, and kept for five days at a temperature of 25° C. was also prepared. Twenty cub. cm. of this culture was introduced into each of the flasks, and, after agitation of the contents, three specimens from each flask were taken by means of a pipette at intervals of 10, 30, and 60 minutes: also in 6, and 24 hours, and cast into sterile plates of gelatin for cultivation. Control tests were also made from similar flasks filled with 100 cub. cm. of sterilised distilled-water, infected in a similar way with a cultivation of cholera-bouillon. The cultures took place at a uniform temperature of 25° C. The experiments indicated that, after the lapse of a given time, even the 1 per cent. solution proved fatal to the cholera germs. In respect to their energy as disinfectants against cholera bacteria, these soaps differed but little. They are all equally capable of being used for this purpose in each case where soap solutions can be employed for disinfection. The advantages they possess over other disinfectants consist in their ready applicability and in their complete freedom from danger.

#### PATENTS.

*Manufacture of Oleaginous or Saponaceous Compounds suitable for producing Medicinal Emulsions for Absorption by the Skin, or for Disinfectants.* F. W. Klever, Brandenburgerstrasse, Cologne. Eng. Pat. 12,446, June 24, 1893.

THE object of this invention is to impart to certain medicaments, such as creosote, camphor, chloroform, eucalyptus oil, and to disinfectants, a permanent or increased capacity for forming emulsions, in order to facilitate their absorption by the skin. Mineral oils (sp. gr. 0.900) are treated with oxygen, preferably under a pressure, varying from 7 to 20 atmospheres, according to the nature of the oil, at a temperature of 150°—200° C., until the oil is oxygenated. Then alkalis (preferably soda or ammoniac) are added in quantity not exceeding 5 to 7 per cent. of the oil, and to prevent the oil becoming thick, a small quantity of alcohol, not exceeding 1½ per cent., may

be added to it. The product is capable of forming, with water an emulsion, from which the oil will not separate; in this state it will dissolve certain medicaments and disinfectants which have hitherto been considered to be insoluble, thus rendering them capable of being readily absorbed by the skin.—J. J. K.

*A New and Improved Hydrostatic Apparatus for Automatically Mixing with Water, or other Liquid, Disinfectants, Softening or Purifying Substances, or Saturated Solutions of any Soluble Substances in Definite Proportions.* F. Spence, Newcastle. Eng. Pat. 13,146, July 5, 1893.

See under I., page 713.

*An Improvement in what is commonly called Dry Soap or Soap Powder.* W. H. Horton, Manchester. Eng. Pat. 8676, May 2, 1894.

See under XII., page 746.

## XIX.—PAPER, PASTEBOARD, Etc.

#### PATENTS.

*An Improved Machine for Straining Pulp and the like.* P. Reinicke, Cöthen, Germany. Eng. Pat. 11,531, June 12, 1893.

See under I., page 713.

*Improvements in Apparatus for Mixing and Regulating Paper Stuff.* W. Borland, Currie, Midlothian. Eng. Pat. 12,420, June 24, 1893.

IN the apparatus for regulating the density of the paper pulp an agitator is placed in a vessel separated from the hydrometer-vessel, the hydrometer regulating the required quantity of size-water.—H. S.

*Improvements in or connected with Boilers for Boiling or Chemically Treating, and for Washing Esparto and other Grasses, Straw, Wood, Rags, and other Fibrous Materials for Paper-making.* G. Sinclair, Leith. Eng. Pat. 13,175, July 6, 1893.

AN addition to the now well-known "Sinclair" boiler (Eng. Pat. 2035, 1880; 6441, 1893) of an inlet pipe (steam), whereby a circulation of the boiling liquor in the reverse direction is determined, i.e., upwards through the fibrous material and returning *via* the vomiting pipe. An injector is also added in connection with this pipe for the admission of air or water. The patentee "claims" the additional inlet pipe and injector as described and figured (*q.v.*).

—C. F. C.

*A New or Improved Material capable of being used in Substitution for Leather and for Ordinary Paper.* N. Kinnagaya, Osaka, Japan. Eng. Pat. 19,481, October 17, 1893.

STRONG paper, such as made from Manilla hemp or from fibres of the kozo tree of Japan, is mixed or impregnated with gelatinous matters during, or subsequent to, its manufacture. The paper sized in this manner with gelatin is brushed or otherwise wetted with a solution containing tannic acid and dried. This operation is repeated two or three times, the tannin liquid employed being a solution made from persimmon, or an oak-bark solution of a strength of from 25 to 33 Tw. The material, after having been finally dried, may be employed as a substitute for leather or ordinary paper for various purposes, e.g., for wrappers and linings, for covering the rollers used in spinning machinery, &c.—H. S.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Mercurous Iodide obtained Crystallised by the Wet Process.* François. Jour. Pharm. et de Chim. [5], 29, 67.

50 GRMS. mercuric iodide, 100 aniline, and 200 of alcohol of 90 are heated until solution is effected; the liquid is filtered and allowed to stand some days. Crystals of diphenylmercuriodiammonium iodide separate; to the clear filtrate from these, 350 grms. of commercial ether of 65 are added, and the whole allowed to stand for a week. Owing to the presence of aldehyde in the ether the mercuric iodide present becomes reduced to mercurous iodide, which separates in yellow scales. After washing successively with cold alcohol, boiling alcohol, and ether, the salt is obtained pure; it sublimes in orange-yellow crystals. Treated with potassium iodide under the microscope it dissolves with separation of shining globules of mercury.—C. R. A. W.

*Chloralose.* M. Hanriot and C. Riche. Bull. Soc. Chim. 1894, 11, 37—44.

CHLORAL unites with glucose, forming well-crystallised compounds. These were first obtained by Heffter in 1889.

The method of preparation consists in heating on the water-bath a mixture of equal parts of glucose and chloral, both in the anhydrous condition. A vivid reaction sets in and a readily soluble, vitreous mass is produced. From this the uncombined chloral is removed by boiling with water. The concentrated aqueous solution deposits a crystalline mass, from which, after drying and repeated washing with hot ether, boiling alcohol extracts a substance crystallising in fine iridescent scales, which by the authors is called para-chloralose. By exhausting the aqueous solution, from which the para-chloralose has been separated, with the ether used for washing the latter, and evaporating the ethereal solution, beautiful needles of chloralose are obtained. The composition of both these compounds corresponds to the formula  $C_6H_{11}Cl_3O_6$ .

*Chloralose* melts at  $187^\circ$ , is fairly soluble in water, alcohol, and ether, slightly soluble in chloroform, and almost insoluble in petroleum. It does not reduce Fehling's solution or silver nitrate. Dilute acids split it up only after long continued boiling. By alkalis it is rapidly decomposed on heating. It combines neither with phenylhydrazine nor with hydroxylamine. By acetyl and benzoyl chlorides it is readily converted into the corresponding tetra-derivatives, and with sulphuric acid it forms the unstable compound  $C_6H_9Cl_3O_4(SO_4H)_2$ .

*Chloralic Acid*,  $C_6H_5Cl_3O_6$ .—Obtained by adding 50 grms. of nitric acid, and subsequently a solution of 20 grms. potassium permanganate to 30 grms. of chloralose dissolved on the water-bath in one litre of water. From the residue resulting by the evaporation of the ethereal extract of the solution concentrated *in vacuo* the sodium salt is prepared. This, after washing with ether, is decomposed with dilute sulphuric acid, the free chloralic acid being subsequently extracted by means of ether, from which it crystallises in fine needles melting at  $212^\circ$ .

Chloralose is a powerful hypnotic. Its ethers, as well as chloralic acid, are physiologically inactive.

*Para-chloralose* crystallises in shining prisms, melting at  $227^\circ$ . It is almost insoluble in water, chloroform, and ether, but dissolves pretty freely in boiling alcohol and in caustic potash. With Fehling's solution, silver nitrate, dilute acids, phenylhydrazine, and hydroxylamine it behaves in the same manner as chloralose. By alcoholic potash it is rapidly decomposed. Like chloralose it combines with acetyl and benzoyl chlorides and with sulphuric acid. The acetyl and benzoyl derivatives are less stable than the corresponding chloralose compounds, while the sulphuric ether shows a somewhat higher degree of stability than that of chloralose.

*Para-chloralic Acid.*—Prepared in much the same manner as chloralic acid. Large crystals containing two molecules of water. Melting point  $202^\circ$ . Extremely soluble in alcohol. The sodium salt crystallises in lustrous scales.

Para-chloralose and its derivatives possess no hypnotic properties.—E. M.

*Chloralose.* M. Hanriot and C. Riche. Bull. Soc. Chim. 11—12, 1894, 303—305.

CHLORALOSE is soluble in alkalis, but does not combine with them to form compounds analogous to saccharates; thus ether dissolves it completely from potash solution, whilst the ammoniacal solution loses all ammonia by exposure to air, leaving only chloralose behind. No carbon dioxide is evolved from alkaline carbonates by chloralose. Neither chloralose nor para-chloralose (when pure) reduce Fehling's solution until decomposition has been more or less effected by the potash present; nor do dilute acids act on chloralose even after several hours heating; although, as shown by Petit and Polonowsky, more concentrated acids hydrolyse it into chloral and glucose. Saturated hydrochloric acid at  $120^\circ$  does not act thus upon it.—C. R. A. W.

*Researches on the Homologues of Gallanilide: Galliparalulide.* P. Cazeau. Bull. Soc. Chim. 11, 1894, 82—85.

WHEN equal weights of paratoluidine and gallic acid are heated together at  $150^\circ$  C., *galliparalulide*,  $C_{17}H_{15}NO_6$ , is formed. It crystallises with 2 aq. in white flakes, melts at  $211^\circ$  C., is soluble in alcohol, ether, and boiling water, very sparingly so in cold water. It loses its water of crystallisation at  $100^\circ$ . It is decomposed by hydrochloric acid at  $150^\circ$ ; alkalis appear to have no action on it even at  $100^\circ$ . It oxidises and becomes brown on exposure to air. With acetic anhydride it yields a *triacetyl derivative*—

crystallising in needles which do not melt without decomposition, and are soluble in alcohol and insoluble in water. The acetyl compound has no action on ferric chloride, whilst the base gives a blue colour therewith. A boiling solution of the toluidide yields with zinc acetate a *zinc salt*,  $C_{14}H_{11}NO_4Zn$ , which is insoluble in water. Corresponding *lead, barium, and calcium* salts were obtained.

Attempts to produce similar derivatives from orthotoluidine, methylalanine, dimethylalanine, and xylyline, have so far proved unsuccessful.—L. T. T.

*Germicidal Action of Gallanilide or Gallanol.* P. Cazeau. Bull. Soc. Chim. 11, 1894, 81—82.

IN conjunction with Nicolas, the author has investigated the germicidal effect of gallanilide (or gallanol) on the carbuncle bacillus, the bacillus staphylococcus, bacillus pyocyaneus, Eberth's bacillus, and the intestinal bacilli. With large doses of the germicide all the bacilli were killed; with small doses (1 in 1,000) the Eberth's bacilli were killed, the vigour and reproduction of the intestinal bacilli and the staphylococci was reduced, but no result could be observed on the other two species; with very small doses (1 in 5,000) no result was observed on the growth of the bacilli, but their pathogenic action was almost completely destroyed. G. Roux finds a similar destructive effect of this reagent on the cholera bacillus, but has not yet completed his researches.

Gallanilide acts like salicylic acid in preventing the putrid fermentation of eggs and blood, or the turning of milk, and has the advantage over salicylic acid of being non-toxic (unless injected directly into the blood) in doses of as much as 5 grms. The non-toxic effect is due to its insolubility in water.—L. T. T.

Pure *d*-Coniine. A. Ladenburg. Ber. 27, 858—859.

SPECIMENS of natural coniine yielded to the author specific rotatory powers not exceeding  $\alpha_D = 13.8^\circ$ , the value found for synthetic coniine; latterly a sample was obtained of higher value. By conversion into bitartrate and frequent crystallisation of the salt, the alkaloid ultimately regenerated was found to boil at  $166^\circ$ — $167^\circ$ , and to have the rotatory power,  $\alpha_D = 15.6^\circ$ , the value ascribed by Schiff to *d*-coniine. Pure *d*-coniine platino-chloride dissolves completely in alcohol-ether, and separates in a crystalline form on evaporation; whereas if impure, an oil first separates, only becoming crystalline on standing for some time.

—C. R. A. W.

Isoborneol. J. Bertram and H. Walbaum. J. Prakt. Chem. 1894, 49, 1—15.

WHEN camphene is warmed with a mixture of glacial acetic acid and a small quantity of a mineral acid (sulphuric, nitric, &c.), it is rapidly converted into the acetic ether of isoborneol,  $C_{10}H_{17}.COOC_{10}H_{17}$ , from which the solid alcohol, isoborneol,  $C_{10}H_{17}.OH$ , is readily formed by the action of alcoholic potash. The reaction occurs equally well whether the camphene be of natural origin or formed from bornyl chloride or from pinene hydrochloride.

Isoborneol differs from borneol in several marked ways, more particularly in readily losing the elements of water, reproducing the parent hydrocarbon; thus heating with zinc chloride or diluted sulphuric acid, readily forms camphene, under conditions where pure borneol is not all acted upon. Borneol melts at  $203^\circ$ — $204^\circ$ , isoborneol at  $212^\circ$ ; owing to extreme volatility, the melting point must be determined in a sealed capillary tube; for the same reason the boiling point cannot be determined; that of borneol is  $212^\circ$ . The solubilities in benzene and petroleum ether are different; and various differences in melting point, &c., are observed in the case of corresponding pairs of derivatives, such as the phenylurethanes, chloral compounds, bromal compounds, formic and acetic esters, and methylene ethers. On the other hand, by oxidation, each gives ordinary camphor, melting at  $177^\circ$ , and boiling at  $207^\circ$ — $208^\circ$ , and yielding an oxime, melting at  $118^\circ$ — $119^\circ$ . When isoborneol is dissolved in methylic or ethylic alcohol and warmed with sulphuric acid, the methylic and ethylic ethers are respectively formed, boiling at  $192^\circ$ , and  $203^\circ$ — $204^\circ$ ; borneol is unacted upon under similar conditions. Isoborneol is present to some extent in the crude borneol obtained by the reduction of camphor.—C. R. A. W.

The Occurrence of Camphene in Ethereal Oils. J. Bertram and H. Walbaum. J. prakt. Chem. 1894, 49, 15—19.

CAMPHENE is distinguished from all the other terpene isomerides by its solid form, and by being converted into isoborneol acetic ether by treatment with glacial acetic acid and a little sulphuric acid. By means of this latter reaction, its presence has been detected in various essential oils, the fraction passing over between  $155^\circ$  and  $165^\circ$ , or thereabouts, being treated with these acids, and the undissolved hydrocarbons, &c. separated. On adding water to the acid solution, an oily fluid separates, largely consisting of isoborneol acetic ether, and furnishing isoborneol on saponification with alcoholic potash. In this way citronella oil was found to contain notable quantities of camphene, not so easily separated as solid hydrochloride by dissolving in ether and saturating with gaseous hydrochloric acid. Oil of ginger (*Zingiber Officinale* Roscoe), Kessö oil (from Japanese valerian roots), and camphor oil were similarly found by this mode of treatment to contain, *inter alia*, small quantities of camphene.—C. R. A. W.

Presence of Camphene in Essence of Lavender.

G. Bouehardat. Bull. Soc. Chim. 11, 1894, 147—150.

By the distillation of large quantities of essence of lavender, the author obtained a small quantity of liquid boiling at  $165^\circ$ — $170^\circ$  C. from which, by means of the hydrochloride,

he succeeded in isolating a dextro-rotatory camphene, boiling at  $158^\circ$ — $160^\circ$  C., and showing all the characteristics of ordinary camphene. The hydrochloride has an opposite rotation to the hydrocarbon, and the latter, when treated with formic acid at  $100^\circ$ , yields a borneol; thus proving it to be a camphene. The camphene appeared to be associated with a terebenthene.

In opposition to Barbier, the author maintains that the linalol obtained by him from essence of lavender is identical, and not isomeric, with the licareol found by Morin in essence of *licari kanali*, and that the geraniol which the author obtained from linalol is also identical with the licarhodol obtained by Barbier from licareol.—L. T. T.

Composition of Essences of Fir Needles. J. Bertram and H. Walbaum. Arch. der Pharm. 231, 299.

THE fragrant principles of these essences is the acetic ether of levo-borneol, identical with the synthesized product. Each species contains a certain number of terpenes. When the essence is distilled, the borneol acetate is decomposed, and the acetic acid liberated causes the polymerisation of a part of the terpenes. The following table gives the composition and physical properties of the principal essences:—

Origin.	Density at $15^\circ$ .	Rotation ( $l = 100$ ).	Composition.
Needles of <i>abies pectinata</i> .	0.875	$-20^\circ 40'$	Levo-pinene, levo-limonene, borneol acetate (1.5 per cent.), sesquiterpene.
Cones of <i>abies pectinata</i> .	0.854	$-72^\circ$	Levo-pinene and levo-dimanicene.
<i>Abies canadensis</i> .	0.907	$-29^\circ 54'$	Levo-pinene, borneol acetate (3.6 per cent.), and sesquiterpene.
<i>Picea vulgaris</i> ...	0.888	$-21^\circ 40'$	L. pinene, L. phellandrene, dipentene, borneol acetate (8.3 cent.), and sesquiterpene.
<i>Pinus pumilis</i> Haenke.	0.845	$-9^\circ$	L. pinene, L. phellandrene, silvestrene, borneol acetate, sesquiterpene.
<i>Pinus sylvestris</i> (Swedish).	0.872	$+10^\circ 40'$	Dextro-pinene, d. silvestrene, borneol acetate.
<i>Pinus sylvestris</i> (German).	0.886	$+10^\circ$	D. pinene, d. silvestrene, dipentene, sesquiterpene, borneol acetate.

The authors have also prepared the following ethers of dextro-borneol:—

Ether.	Boiling Point under 10 mm.	Rotary Power ( $l = 100$ mm.)	Density at $15^\circ$ C.	Refractive Index $n_D^{20}$ at $115^\circ$
Formate.....	$90^\circ$ C.	$+31^\circ$	1.013	1.47078
Acetate (levo).....	$98^\circ$	$-35-26'$	0.991	1.46635
Propionate.....	$109^\circ$ — $110^\circ$	$+21^\circ$	0.979	1.46435
Butyrate.....	$120^\circ$ — $121^\circ$	$+22^\circ$	0.966	1.46380
Valerate.....	$128^\circ$ — $130^\circ$	$+26^\circ$	0.956	1.46280

—L. T. T.

A New Derivative from Coto-bark. G. Ciamician and P. Silber. Ber. 27, 841—850.

IN the course of manufacture of cotoine by E. Merck, of Darmstadt, a substance was isolated apparently novel. After crystallisation from petroleum ether it melted at  $68^\circ$ , and gave numbers on analysis leading to the formula  $C_{11}H_{16}O_2$ ; further investigation showed that its relationship to paracotoine is indicated by the occurrence in the latter of the group  $C_6H_5(CH_2O_2)$ , represented in the former by

$C_6H_5$ ; i.e., that the new body contains a phenyl group, which in paracotone is converted into a dioxymethylene-phenyl group.

The new body (phenyleumaline) is readily soluble in ether, alcohol, glacial acetic acid, and chloroform. Methyl alcohol dissolves it freely at the ordinary temperature, but a good deal crystallises out again at 0°. Warm petroleum ether dissolves it to some considerable extent. It melts under boiling water, and crystallises from solutions therein in thin plates. Acetic anhydride forms no acetyl derivative; nor is any methoxyl, &c., indicated by Zeisel's test; so that no hydroxyl, ethoxyl, or methoxyl is present (as with paracotone). Various substitution derivatives are described, e.g., a bromo-derivative,  $C_{11}H_7BrO_2$ , and a nitro-derivative,  $C_{11}H_7(NO_2)O_2$ ; the actions of phenylhydrazine, caustic potash, hydrochloric acid, and methyl iodide (in presence of alkalis) have also been studied.

—C. R. A. W.

**Occurrence of Trigonellin in the Seeds of *Pisum Sativum* and *Cannabis Sativa*.** E. Schulze and S. Frankfurt. *Ber.* 27, 769—770.

TRIGONELLIN,  $C_8H_7NO_2$ , has been found by Jahns to be identical with Hantzsch's synthetic methylbetaine of nicotinic acid, and to occur in the seeds of *Trigonella fauon grecum*. Schulze found it in ordinary peas (*Pisum Sativum*), and the authors have obtained it from hempseeds (*Cannabis Sativa*). It forms two aurochlorides; one melting without decomposition at 198°, and indicated by the normal formula,  $C_8H_7NO_2 \cdot HCl \cdot AuCl_3$ ; the other crystallising in fine needles melting at 186°, and indicated by the formula 4 ( $C_8H_7NO_2$ ), 3 HCl, 3  $AuCl_3$ . The platinochloride can crystallise either anhydrous, or with 4 molecules of water. The quantity present in hempseed is very small.—C. R. A. W.

**The Alkaloids of the *Papaveraceæ*: Codeine.** W. Gochlich. *Arch. der Pharm.* 231, 235.

THE author has repeated and amplified some of the experiments of various chemists who have examined codeine salts and derivatives. He describes the hydrobromide, hydriodide, sulphate, chromate, acetate, salicylate, chloraurate, chloroplatinate, and chloromercureate. By the action of phosphorus pentachloride in chloroform solution, the *chlorocodide* of Matthiessen and Alder Wright is obtainable in purer condition than by the action of hydrochloric acid; it crystallises from petroleum spirit in sparingly soluble scales, melting at 118°, and forms a chloroaurate, fusible at 171°—172°. Alcoholic potash in sealed vessels at 120°—130° transforms chlorocodide into *apocodine*; but neither sodium and alcohol, nor tin and hydrochloric acid avail to remove the chlorine. Concentrated sulphuric acid converts codeine into a sulphonated derivative, the *sulphocodide* of Anderson; diluted acid forms the "amorphous isometide of codeine" described by Armstrong; this the author has obtained in crystalline crusts, fusible at 180°; it gives the same colour reactions as codeine, but is precipitated by sodium carbonate. The author regards it as identical with the "pseudocodeine" of Merck, and describes the hydrochloride, sulphate, chloraurate, and chloroplatinate. Pseudocodeine contains a methyl group, but differs from codeine in not containing a hydroxyl group, so that it neither reacts with acetyl chloride nor with acetic anhydride.

—C. R. A. W.

**Carpaïne.** J. J. L. van Ryn. *Arch. Pharm.* 231, 184.

THE best mode of extraction of this alkaloid is to digest the finely powdered dry leaves of *carica papaya* with alcoholic hydrochloric acid, and subsequently with alcohol; after evaporating the extract to a syrup it is treated with watery acid, whereby chlorophyll remains undissolved. The watery solution is treated with ether to remove resin, and then with soda and ether so as to dissolve out the alkaloid in the usual way. The yield is about 0.08 per cent. of the weight of the leaves. Carpaïne is very bitter, perceptible even in a dilution of 1 in 100,000. It is insoluble in water, but readily soluble in various organic solvents, e.g., in 5.5 times its weight of benzene; in 9 times of absolute alcohol, and of

amyl alcohol; in 103 of petroleum ether; and in 574 times its weight of alcohol of density 0.95; in carbon disulphide and chloroform it is soluble in all proportions. It melts at 121° and can be sublimed with partial decomposition. Its rotatory power does not vary with the concentration;  $[\alpha]_D^{20} = +21.9$ . Carpaïne gives no colour reaction with concentrated acids, nor with sulphuric acid and potassium bichromate; its composition is indicated by the formula,  $C_{14}H_{21}NO_2$ . It precipitates with gold chloride, platonic chloride, potassium iodomercureate, phosphomolybdic acid, phosphotungstic acid, picric acid, and iodised potassium iodide solution. Various of its salts are described; the chloroplatinate, chloraurate, hydrochloride, hydrobromide, hydriodide, sulphate, and nitrate. Carpaïne appears to be a secondary base, as its compound with ethyl iodide is decomposed by potash, forming *ethyl carpaïne*—

This base is crystallisable from alcohol; it melts at 91°, and combines with ethyl iodide forming a crystallisable ethyl carpaïne ethioidide, not decomposed by soda, but acted upon by silver chloride, and silver oxide, forming further tertiary ammonia derivatives. Carpaïne is not acted upon by benzoyl chloride, nor by acetyl chloride; with nitrous acid it forms a nitroso derivative,  $C_{14}H_{21}(NO)NO_2$ , crystallisable in colorless prisms, soluble in alcohol.—C. R. A. W.

**Alkaloids from the Seeds of *Lupinus Albus*.** A. Soldani. *Arch. der Pharm.* 231, 321.

THE author has extracted two isomeric alkaloids from these seeds. The first is a solid melting at 99° C., very soluble in water, alcohol, and chloroform, less so in benzene, very sparingly so in light petroleum. Its aqueous solution is strongly alkaline and becomes turbid at the boiling point. The alkaloid has a strong odour of sperm, and a bitter taste. The hydrochloride gives a yellow precipitate (soluble to a blue solution in ammonia) with phosphomolybdic acid, a brown precipitate with a potassium iodide solution of iodine, white precipitates with Meyer's reagent and with phosphotungstic acid, and yellowish-orange precipitates with bromine water and Dragendorff's reagent. It is inactive towards polarised light. The *hydrochloride*,  $C_{15}H_{21}N_2O \cdot HCl + 2H_2O$  forms deliquescent prisms soluble in alcohol and melting at 105°—107° C. The *hydriodide* forms yellow anhydrous crystals melting at 179—180° C., the *platinochloride* orange needles melting with decomposition about 200°; the *aurochloride*, orange needles melting at 182°—183°; the *thiocyanate*, + aq., large crystals melting at 123°—124°; the *methiodide* crystals melting at 237°—238°; the *tribromide*,  $C_{15}H_{21}N_2O \cdot Br_3$ , orange crystals melting at 123—124°; and the *picrate*, *oxalate*, and *tartrate* well formed crystals.

The second alkaloid is a liquid which, when kept over sulphuric acid, deposits large prisms which are, however, so deliquescent that they could not be isolated. Its solutions are dextrorotatory. The *hydrochloride*, + 2 aq. forms colourless prisms soluble in alcohol and in water, insoluble in ether, and melts at 132—133°, or in anhydrous prisms melting above 135°. Alcoholic potash decomposes it, yielding a substance differing from the original alkaloid. The *hydriodide* forms crystals melting at 184—185°; the *platinochloride* ( $C_{15}H_{21}N_2O \cdot HCl$ )<sub>2</sub>PbCl<sub>4</sub> + 4 aq. orange needles or prisms melting with decomposition at 120—125°; the *aurochloride*, yellowish-red crystals melting about 199°—200°; the *thiocyanate* + aq. yellow crystals melting at 183—184°, and the *methiodide* melts at 231—232°. This alkaloid is probably identical with Hagen's lupanine. Both alkaloids are tertiary monatomic bases and both toxic, though in different degrees.—L. T. T.

**Active Principle of *Cientia Virosa* Grains.** J. Frapp. Petersburg. *Arch. der Pharm.* 231, 212.

ON treating the seeds with a weak alkaline solution and distilling with water, cymene and cumenic aldehyde were obtained; but the nature of the toxic principle could not be determined.—C. R. A. W.

*A Study of Eserine.* A. Petit and M. Polonovsky. Bull. Soc. Chim. 1893, 9, 1008—1015.

Eserine melts at 105—106°, not at 69° as is very generally stated. Its rotatory power is as follows:—In chloroform,  $\alpha_D = -82$ ; in 98 per cent. alcohol,  $\alpha_D = -89$ ; in benzene,  $\alpha_D = -120$ ; in toluene,  $\alpha_D = -120$ .

Since the salicylate is the only salt of those heretofore known that is not very deliquescent, and since eserine has considerable therapeutic value, the authors have prepared the following salts:—

*Eserine benzoate.*—This is prepared by mixing ethereal solutions of eserine and of benzoic acid, and evaporating the ether, when the new salt separates in short white prisms; it is not deliquescent, and it melts at 115—116°. It is very soluble in water (1:4 at 18°) and alcohol yielding neutral solutions.

*Eserine metacresolate.*—

This is made by mixing ethereal solutions of eserine and of metacresotic acid, when the new salt is precipitated in the form of small white prisms. It melts at 156°—157°, and is sparingly soluble in water (1.7 grms. in 100 cc. at 15°); the solution is neutral. This salt does not deliquesce.

*Eserine hydrogen citrate*, prepared as a precipitate by mixing ethereal solutions of eserine and of citric acid, and *normal eserine tartrate*, made by dissolving eserine in tartaric acid and crystallising over sulphuric acid, are both very deliquescent.

An investigation into the chemical nature of eserine has led to the following conclusions:—(1.) Eserine is a mono-acid, tertiary base. (2.) Only one of the three nitrogen atoms imparts a basic character to eserine. (3.) One of the nitrogen atoms is attached to a  $CH_3$  group. (4.) The nitrogen atom of this substituted group does not appear to be the same as that which fixes alkylidide in such compounds as eserine methiodide. (5.) The grouping  $X-CO-C$  is probably present. (6.) The second oxygen atom appears to be of a phenolic character.

The authors suggest the constitutional formula—

as representing the above conclusions.—A. G. B.

#### *The Volatile Hydrocarbons of Essence of Valerian.*

Oliviero. Bull. Soc. Chim. 11, 1894, 150—152.

The author has examined the more volatile portions (boiling below 180° C.) of essence of valerian. In these he found a levo-rotatory camphene boiling at 157°, melting above 0°, giving a rotation  $[\alpha]_D = -21^\circ$  and yielding a hydrochloride having a rotation  $[\alpha]_D = +10^\circ$ ; and also a levo-rotatory terebenthene yielding a levo-rotatory hydrochloride of rotation  $[\alpha]_D = -25^\circ$ . A small quantity of a citrene is also present. As considerable quantities of valeric acid are obtained during the steam distillation of the valerian roots, the author suggests that the camphene may very probably be derived from a borncol valerate present in the root.—L. T. T.

*Essence of Ylang-Ylang.* A. Reyhler. Bull. Soc. Chim. 11, 1894, 407—412.

GAL, (Comptes rend. 76, 1482) states that this substance distils between 160° and 300° C., without leaving any residue, contains no aldehydes and yields on saponification benzoic acid and a mixture of alcohols insoluble in water and boiling between 170° and 200° C., but the nature of which he did not determine. Flückiger and Convent in 1881 (Arch. d. Pharm. [3], 13, 24), state that benzoic acid is only present in this essence in very small quantities, and that it is accompanied by a phenol and an aldehyde or ketone. The author believes these investigators to have been working on different materials, as two preparations, *oleum Annonae odoratissima* made in the Philippine Isles, and *oleum Canangae*, a less pure substance obtained from Java, the Indies, or Réunion, go under the same name. He is therefore examining the former or true Ylang-Ylang again. He obtains two chief fractions boiling under 23—30 mm. pressure at 100—112°

C. and 130°—145° C. respectively. The fraction of lower boiling point yields on saponification large quantities of benzoic acid and an alcohol of the formula  $C_{10}H_{18}O$ , resembling and either identical or isomeric with geraniol, to which the author gives the provisional name of ylangol. It boils at 103—107° under 23—30 mm. pressure, has a density of 0.886 of 15 and has at 15° the refractive coefficient 1.47165. The rotatory power is  $[\alpha]_D = -20.7$ . He has not yet determined what other alcohols are present in this fraction. The fraction of higher boiling point appears to contain a terpene, but is still under investigation. He has not been able to obtain any aldehyde from this essence.—L. T. T.

*Bulgarian Essence of Roses.* W. Markownikoff and A. Reformatsky. Soc. Ph. Ch. de St. Petersburg, 1892, 9.

WITHOUT knowing of Eckart's work on this subject (this Journal 1892, 265) the authors have investigated the composition of Bulgarian rose oil. The substances examined were derived from three different sources, and were viscous solids containing paraffin-like crystals and melting at about 23—24° C. They were all levorotatory. The stearoptene was separated by freezing out. Of the residual eleoptene the greatest part boils about 222°—222.5° C., and is an alcohol of the formula  $C_{10}H_{20}O$ . It takes up two atoms of bromine, indicating the presence of one double linking and appears therefore to belong to the allyl series. The acetate  $C_{10}H_{18}O \cdot COCH_3$  is a very mobile colourless liquid having an odour quite different from that of the alcohol; the alcohol (which the authors term *roseol*) has no action on ammoniacal silver nitrate. It is oxidised by potassium permanganate to a trihydric alcohol  $C_{10}H_{19}(OH)_3$  which is soluble in water, sparingly so in alcohol and in ether. The triacetate is a yellow liquid of aromatic odour which is not viscous at -10°, and is insoluble in water, soluble in ether and in alcohol. With  $H_2$  at 180°—200° a hydrocarbon  $C_{10}H_{20}$  is formed.

The stearoptene  $C_{16}H_{34}$  is a crystalline solid, becomes viscous at 34° and melts at 35.5—36.8°. It is a hydrocarbon of the paraffin series.—L. T. T.

*Extract of the Root of Aspidium Filix.* A. Ehrenberg. Arch. der Pharm. 231, 345.

This root contains an acid (already described under various names); and an oil to which it probably owes its vermifugal properties. This oil only appears in the root in the autumn. It is a yellow liquid of penetrating odour and acid reaction; has a specific gravity of 0.85—0.86, boils with partial decomposition between 140° and 350° C., and distils with steam. 100 kilos. of root gathered in the autumn yielded 40 grms. of the essence. Robert finds that as a medicine a small dose of this essence kills the principal species of worms. Subjected to fractional distillation it yielded propionic, butyric, and caproic acids, leaving a residue consisting of the hexylic and octylic ethers of butyric, caprylic, and pelargonic acids. The essence also contains small quantities of aromatic alcohols and of cineol, to which its properties as a vermifuge are probably due.—L. T. T.

*Pyrazolone Reactions.* R. v. Rothenburg. Ber. 27, 782.

See under XXIII., page 765.

*Conicine and Nicotine.* G. Heut. Arch. der Pharm. 231, 376.

See under XXIII., page 767.

#### PATENTS.

*Manufacture of Geraniol from Citronella-oil.* J. Bertram, Leipzig, Germany. Eng. Pat. 13,401, July 10, 1893.

THE investigations conducted by the patentee have shown that citronella-oil contains pinene, camphene, and dipentene, as well as *citronell-aldehyde* (*citronellone*)  $C_{10}H_{18}O$ . The oil contains also a considerable amount of a substance

identical with geraniol, the aromatic constituent of palmarosa-oil and of geranium-oil, accompanied by small quantities of fatty acid esters of geraniol and of sesquiterpene.

The first claim is embodied in the following paragraph:—

The citronellon above referred to is removed by shaking citronella-oil (100 kilos.) with concentrated sodium bisulphite solution (20—40 kilos.). After cooling, the oil is separated by pressure or suction from the bisulphite compound, and it is boiled with potassium hydrate (6 kilos.) dissolved in alcohol (25 kilos.). After distilling off the alcohol, and driving over the oil with a current of steam, the geraniol is purified by fractional distillation *in vacuo* or with steam. If it be not desired to recover the citronellon, the citronella-oil (100 kilos.) is heated without previous treatment with potassium hydrate (10—15 kilos.) dissolved in alcohol (50—70 kilos.) for about three hours, and the residual oil treated as already described.

Jacobsen has shown (*Annalen*, 157, 232) that geraniol forms crystalline compounds with the chlorides and nitrates of calcium and magnesium. The patentee claims also the use of these for the purification of crude geraniol; *e.g.*, equal parts of powdered calcium chloride and of crude geraniol are mixed; the oil is separated from the resulting solid mass by pressure, suction, or centrifugal action. The mass is then washed with ether, light petroleum spirit, chloroform, &c., and the geraniol, regenerated by treatment with water, is purified by distillation *in vacuo*.—A. R. L.

**Improvements in Bottles for Holding or Containing Poisons or Poisonous Liquids.** R. H. Quine, Pendleton, Lancashire. Eng. Pat. 14,553, July 28, 1893.

See under I., page 713.

**Improvements in the Manufacture of Compounds for Alimentary and Medicinal Purposes.** J. Y. Johnson, London. From C. F. Boehringer und Soehne, Waldhoff, Germany. Eng. Pat. 15,714, August 18, 1893.

A FURTHER improvement in the process described in Eng. Pat. 818 of 1893 (this Journal, 1893, 370). The improvement is as follows:—After the albumen solution has been heated on a water-bath for about 5 hours with soda-lye, tartrate of iron, and tartrate of sodium (*loc. cit.*), a current of steam is passed into the liquid until it has attained a temperature of 96° C. Subsequently, without stopping the current of steam, small quantities of tartaric acid or of hydrochloric acid are introduced until the solution has a perfectly neutral reaction; additional quantities of acid are added after the lapse of a few minutes until the solution is distinctly acid. When the solution becomes clear it is allowed to cool, filtered, and the filtrate heated at 92° C. with ammonia (1 part of 30 per cent. ammonia for every 10 parts of albumin); the further treatment has already been described. The claim is for the introduction of acid into the hot solution and the separation thereby of unchanged albumin and other extraneous matter.

—A. R. L.

**Manufacture of Esters, Phenol, and other Ethers by Means of Aromatic Sulphonic Acids.** F. Krafft and A. Roos, Heidelberg, Germany. Eng. Pat. 6190, March 27, 1894.

This specification relates to an extension of Eng. Pat. 21,938 of 1892 (this Journal, 1893, 464) to the manufacture of esters of acids and phenols.

By heating sulphonic esters (*loc. cit.*) with carboxylic acids the esters of the latter and free sulphonic acids are obtained. If, for example, a continuous stream of a mixture of acetic acid and ethyl alcohol be added to  $\beta$ -naphthol sulphonic acid heated to 125°—135° C., the distillate will contain, besides acetic acid and alcohol, ethyl acetate and water, the sulphonic acid being regenerated. The reaction takes place in two stages, thus:—

For the manufacture of esters having a high boiling-point the treatment may be effected in a partial vacuum so that the process becomes continuous; liquid acids are added mixed with the alcohols, whilst solid acids are preferably introduced separately.

The sulphonic acids are available for the ethification of those compounds belonging principally to the aromatic series with which sulphuric acid cannot be used because it acts as a sulphonating agent. The numerous carboxylic acids of the aromatic series, as well as phenols, naphthol, aromatic alcohols, hydroxy acids, &c., may be converted into esters by the process.—A. R. L.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

**A New Photographic Printing Paper.** Artigues, Bull. Soc. d'Encouragement, 1894, 93—94.

PREPARED by coating paper, first, with a substratum of gelatin, and then with a very thin film of lamp-black (or other suitable pigment.) For use it is sensitised by soaking for a short time in a 5 per cent. solution of potassium bichromate, and subsequently dried. The sensitised paper will remain in good condition for several days, and the whole of the colouring matter may be removed from its surface by simply washing with warm water. But after exposure behind a negative in the usual way, more or less of the pigment adheres to the film, according to the degree of illumination received. After exposure, the print is soaked in cold water, suspended vertically by its upper edge, and developed by gently pouring over it (both back and front) a thin cream of fine white sawdust (previously boiled and washed with water) and water, at a temperature of 27° C. The gentle friction thus applied to the print suffices to remove the non-adherent portion of the colouring matter from its surface. When development is deemed to be complete, the print is washed two to three times in cold water, passed through an alum bath, again washed, and finally dried. The prints thus obtained are permanent, and are stated to possess a depth and delicacy of half-tone unattainable by any other process.—H. T. P.

### PATENT.

**Improvements in or relating to Colours for and Colouring Photographs and other Articles.** F. C. D. Beacham, Bristol. Eng. Pat. 11,924, July 20, 1893.

COLORS, such as will stand wet processes, as "enamelling," "opalines," &c., after use of mordant, or which will serve for ordinary processes without a mordant, are prepared from alizarine colours dissolved in water and ether, with addition of acetic acid, fused potassa, borax, a bichromate, "kreosote," and tartar. The following ingredients and proportions are recommended: 1 dram of colour; 6 oz. water,  $\frac{1}{2}$  oz. ether, 40 drops acetic acid,  $\frac{1}{2}$  scruple fused potassa, "10 drops boric acid," 20 drops kreosote,  $\frac{1}{2}$  scruple borax, and  $1\frac{1}{2}$  grains tartar. When the photograph is to be treated by wet processes, a mordant bath is used, containing solution in 6 oz. water of 1 dram potash and 1 scruple resin, for stock solution; of which for use 1 oz. is taken to 8 oz. water. A second bath is used containing 2½ parts potassium bichromate and 3 parts tartar to 20 to 30 parts water. Details are given of the manipulation required, and in respect to spotting or re-touching, reference is made to Eng. Pat. 2390 of 1891 (this Journal, 1891, 793). Iron salts may be used to darken the colours, either applied by a brush or as a bath. Tin salts may be used in the same manner, or added to the colour employed. In colouring lantern slides and transparencies, solution of gum arabic, sugar, starch, or dextrin may be applied to any part required to be left white. The film is hardened by a bath of chrome alum. The gum varnish may be applied to photographs, back and front, the gum or like substance being mixed to the consistence of cream with equal parts water and alcohol, a few drops of carbolic acid being added.—E. S.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## PATENTS.

*Improvements in or Connected with Blasting and Blasting Cartridges.* J. Macnab, London, and J. Dickson, St. Albans. Eng. Pat. 9688, May 15, 1893.

THE object of this invention is to prevent blown-out-shots and the dangerous tongue of flame which is forced out and often causes an explosion of the fire-damp and coal-dust of the mine.

The improvements consist essentially in the employment of a metallic device composed of two strong discs of mild steel which are the full diameter of the cartridge case and are connected rigidly together by a strong metal rod. A hole in one of the discs serves for the introduction of the powder into the cartridge, between the discs, and the subsequent insertion of the fuse.

Hermetically sealed tubes containing solutions of ammonia or ammonium nitrate, for the purpose of cooling the flame, may be attached to the connecting-rod of the device prior to charging the cartridge with the explosive. The device acts beneficially by offering longitudinal resistance to the force of explosion, thus relieving the strain on the tamping and preventing blown-out shots.—W. M.

*Improvements in Explosive Compounds.* A. V. Newton, London. From A. Nobel, Paris. Eng. Pat., 11,645, June 13, 1893.

THE inventor makes a smokeless explosive by incorporating nitromannite with nitrocellulose, alone or in combination with other substances. When dry nitrocellulose is used, the nitromannite is dissolved in acetone and then the nitrocellulose is added and thorough incorporation effected by malaxation or kneading, and then the plastic mass can be formed into suitable grains or cords by known means.

When wet nitrocellulose is employed, then the nitromannite is mixed with a volatile solvent, not miscible with water, such as methyl nitrate, methyl, ethyl, or amyl acetates in such quantity as to permit of easy incorporation by what is known as the water method of Lundholm and Sayers (this Journal, 764, 1890), or the nitromannite may first be mixed with dinitrobenzene, mono- or di-nitronaphthalene, &c., and when such mixture is heated on a water bath it easily incorporates nitrocellulose and a cellulosidal explosive is obtained.—W. M.

*An Improved Still or Retort, chiefly to be Used for a Distillation Process.* V. Edwards, Richmond Hill, Surrey. Eng. Pat., 13,567, July 12, 1893.

THE inventor claims the use of a flat bottomed copper flask, tapering towards the top in place of the usual glass flask employed in Kjeldahl's process.—W. M.

*Improvements relating to Electric Fuzes.* F. W. T. Brain, Cinderford. Eng. Pat. 14,091, July 21, 1893.

THE chief feature in this invention is the substitution of silver or platinum for copper phosphide in the firing mixture, which usually consisted of potassium chlorate, antimony sulphide, and copper phosphide.—W. M.

*Improvements in Miners' Squibs.* J. R. Powell, Plymouth, Pa., U.S.A. Eng. Pat. 8097, April 24, 1894.

THIS invention relates to mining squibs, and it has for its object to provide an improved squib of this character, which, while very simple in construction, at the same time provides a perfectly safe one, which can be easily inspected so as to avoid the danger of premature explosion. To this end the main and primary object of the present invention is to form a mining squib having a perfect roll-closure at one end to prevent the powder from working into the match portion, and at the same time to provide a squib wherein the match portion thereof can be easily untwisted its entire

length by the miner before using, in order to ascertain if by any accident any particles of powder had escaped into the same. These objects are attained by the special manner in which the paper wrapper is cut and rolled. The drawings accompanying the specification show the manner of carrying out this invention.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPARATUS, ETC.

*New Form of Mercury Air Pump.* G. W. A. Kahlbaum. Ber. 27, 1386—1394.

THIS modification of the mercury air-pump is more especially intended for use in distillation experiments under diminished pressure. The mercury passes down the fall-tube F into a reservoir V, from which it is again elevated

by means of a water pump, which causes it to ascend through the pipe H, H, so that the supply reservoir R is kept refilled as required. To avoid introduction of water vapour, it is desirable to place phosphoric anhydride in a receptacle between the water-pump and the mercury. By means of the pressure-gauge M, the pressure in the distillation apparatus is readily measured.—C. R. A. W.

Condensers for Laboratories. J. Walter. J. Prakt. Chem. 1894, 49, 41-48.

INSTEAD of a Liebig's condenser, an arrangement is in many cases more convenient where the cooling water is contained in a coil, &c. placed in the interior of the tube or chamber into which the vapour is led. For many purposes it is not necessary that the vapour should be condensed in contact with glass, and in such cases a metal condensing arrangement is convenient. Fig. 1 indicates the section of a

Fig. 2.

Fig. 1.

stellate form, where the cooling water enters and leaves at the top by the connections *t, t*: the cooling surfaces being mostly lateral tubes uniting the ends of the rays, and also the central tube *f*. Fig. 2 represents a worm form, which for a small condensing arrangement may be constructed by coiling up about 120 cm. of metal tubing; copper answers well, especially if tinned or coated with nickel, the outer diameter of the pipe being about 3, and the inner diameter about 2 mm. The cooling water enters at A and leaves at B, or *vice versa*, the condensed liquid dropping out through *m*. Arrangements of this description may be conveniently adapted to extraction apparatus, such as Soxhlet's, and the various modifications thereof subsequently introduced by others, or they may be used as dephlegmators, or as condensers for fractional distillation by passing water, &c. at a given temperature through the coils. For special purposes, where the cost is not prohibitive, silver or platinum tubing may be employed, or copper plated with gold, &c.

—C. R. A. W.

New Apparatus for Fractional Distillation. E. Varenne. Bull. Soc. Chim. 11, 1894, 289-292.

THE condensing column is formed of elements entirely separated from one another, but communicating by means of two tubes connecting each consecutive pair; one traversed by the vapour, the other bringing back the liquid condensed (Fig. 1). A number of comparative trials of the efficiency of this arrangement (six bulbs) as compared with that of the apparatus of Savalle, Le Bel-Henninger (15 plates), and of Claudon-Morin respectively, gave the values,

Apparatus of Savalle .....	1.58
„ Le Bel-Henninger.....	1.56
„ Claudon-Morin.....	1.53
„ E. Varenne.....	1.683
Theoretical coefficient.....	1.025

thus indicating a high degree of superiority of Varenne's arrangement.

Similarly the following figures were obtained as regards the quality of the rectified spirits distilled from the same "low wines" in each case.

	Le Bel-Henninger.	Varenne Small sized Laboratory Model.	Varenne Large Working Factory Model.
Requiring more than 10 minutes to decolorise potassium permanganate.			
More than 15 minutes.	0	30	50
More than 20 „	0	25	35

Fig. 1.

Fig. 2.

The larger size arrangement is thus more effective than the smaller one: Fig. 2 represents this industrial form of the apparatus.—C. R. A. W.

*The Ebullioscope and its Use for estimating Alcohol in Beers.* H. Tornøe. *Bull. Soc. Chim.* **11**, 1894, 115—120.

THE author employs a slight modification of the ebullioscope of Vidal and Mahigand, in which the movable scale is replaced by graduations on the thermometer stem itself. The author has proved that the amount by which the boiling point of water is lowered by the presence of a given quantity of alcohol is independent of atmospheric pressure, but varies sensibly according to the form and size of the apparatus. Employing ebullioscopes of like shape and size these variations may be reduced to negligible quantities. The tables prepared for use with the ebullioscope being based upon the results of experiments with mixtures of alcohol and pure water, it was found that when this apparatus was used with beers, the percentage of alcohol found was always slightly higher than that found by the distillation method. This difference was clearly due to the extract present in beer, but Raoult's work, showing that the lowering influence on the boiling-point of non-volatile substances in solution is inversely as the molecular weights of such substances, seemed to point to any such direct action of the extract (with its high average molecular weight) being far too slight to account for the differences observed. The difference was always found to be least when the proportion of alcohol was largest, and greatest when the extract matter was large. The author points out that in the ordinary distillation method the distillate is made up to the original weight of the beer, and the gravity then taken. Thus, the percentage of alcohol found is not the percentage on the water in the beer, but on the water plus the solid extract, whilst the ebullioscope result is the percentage on the water in the beer, and should be corrected for the solid extract. Based on these considerations, and on the fact that the solution of a given quantity of solid extract in water or in a mixture of water and alcohol, causes the same increase in specific gravity in each case, the author has devised a means by which both a correct estimation of alcohol and also an estimation of the solid extract, may be easily and rapidly made by help of the ebullioscope. If  $S_b$  represents the specific gravity of the beer,  $S_p$  that of the mixture of water and spirit in the beer (which serves as a solvent for the extract) and  $S$  the specific gravity of a hypothetical solution of the solid extract in a weight of water equal to the combined weight of the water and alcohol in the beer, we get the formula  $S_b - S_p = S - 1$  or  $S = 1 + S_b \cdot S_p$ .

The ebullioscope reading gives the percentage of alcohol to water, and from this number, by reference to a specific gravity table of aqueous alcohol,  $S_p$  can readily be obtained.  $S_b$  is readily determined and  $S$  is therefore obtainable. An approximate gravity table of aqueous solutions of solid extract may be easily constructed, and by its help  $S$  will give the solid extract. This number may then be used to correct the alcohol estimation. By this means both the alcohol and the solid extract in a beer may be estimated in about 20 minutes.—L. T. T.

*The Determination of High Temperature by Fusion Tests.* C. Schneider. *Uhländ's tech. Rundsch.* 1894, 54; *Proc. Inst. Civil Eng.* 1894, **116** [ii], 103—104.

THE use of vitrifiable test pieces for the determination of high temperatures, introduced by the late Prof. H. Seger, has been found to be of great value in ceramic manufactures, where the heat to be measured is higher than the melting-points of the metals in ordinary use. The substances used for this purpose are analogous in composition to porcelain glazes containing silica, alumina, ferric oxide, lime, and potash, in varying proportions, the mixtures becoming more refractory as the silica is increased. The different ingredients being thoroughly incorporated into a paste, which is moulded into taper-pointed pieces, either cones or three-faced pyramid, having a number corresponding to the composition impressed upon one side. When required for use, a series of the air-dried cones (ten or a dozen of different numbers, in the case of a preliminary experiment) are placed upon a plate of burnt fireclay, being made to adhere by slightly moistening their bases and rubbing upon the plate, which is then exposed in the

furnace to the heat to be measured. The test-piece is considered to be melted when it is so much softened that the point bends over and touches the surface of the plate, which, with a little practice, can be readily determined.

The standard mixture, or No. 1 at the lower end of the scale, has the following composition.—Silica, 65; alumina, 8.3; ferric oxide, 8.7; lime, 10.6; potash, 7.6 per cent.

Its melting-point is 1,150° C., while that of No. 20, the least fusible number of the series, is 1,700° (near that of platinum), giving a range of 550°, which, divided over the intermediate ones, gives a difference of 28.9 between consecutive numbers, so that collectively they represent the higher portion or gold-platinum series of the Prinscp pyrometer. Until lately, the extension of the scale downwards had not been satisfactorily effected; the most ready method of lowering the fusibility of the standard mixture, namely, the partial replacement of lime by oxide of lead being objectionable, on account of its volatility as well as its liability to reduction when exposed to furnace gases. E. Cramer has, however, found that when half an equivalent of silica, corresponding to 8 per cent. in the above mixture, is replaced by the boric acid, the melting-point is reduced by 190° to 960° C., or that of silver, so that the silver-gold series of alloys can be equally replaced.

The new material is a glass made of the following mixture:—Crystallised borax 193 parts, marble 50 parts, china clay 52 parts, sand 96 parts, melting at 960°. When mixed with No. 1 in such proportions as to vary the contents of boric acid by one-twentieth of an equivalent, a scale of numbers differing in melting-points from each other by 19° is formed, which, to maintain the uniformity with the original series, are numbered from 01 to 010, the latter being the most fusible. The author of the note points out that these tests are likely to be of value in studying the distribution and utilisation of heat in boiler flues, as they can be more easily used than calorimeters or pyrometers. The test-pieces are made by the Royal Porcelain Works, Berlin, in two sizes, about 2½ and 4 inches high.

#### INORGANIC CHEMISTRY.—QUANTITATIVE.

*Corrections to be applied in Titrating Liquids containing Suspended Matter.* E. Lenoble. *Bull. Soc. Chem.*, **11**—**12**, 1894, 336—345.

WHEN a liquid containing matter in suspension is filtered and titrated, the result is too high in reference to the actual fluid present, unless the bulk of the suspended matter is taken into account. If  $V$  be the volume of liquid + solid matter, and  $P$  that of the suspended solids, the result of the analysis is calculated on  $V - P$  instead of on  $V$ . By filtering off a known quantity and titrating, and adding this volume of water to the residue and repeating the operation two figures are obtained, respectively  $A$  and  $B$ , from which the true value may be deduced. Thus the percentage richness of a sugar-beet juice, reckoned on clear liquid + pulp, is—

$$\frac{A^2L}{V(A-B)}$$

when  $V$  is the volume of liquid + pulp operated on, and  $L$  that of the liquid filtered off for the titration. When a vacuum pump is not at hand, and a filter has consequently to be used of considerable volume, the method may be modified by making three determinations: first, a given quantity of fluid is filtered off and titrated, giving the value  $A$  as before; the filter paper and adherent pulp are then put back, and as much water added as will bring the whole to the original volume, so that the solid matter present is now greater than

### EXPLANATORY NOTES.

The Diagram gives the course of prices in England according to my Index Numbers of 45 commodities (before 1846 only 31 principal commodities). It formed part of my paper on "Prices of Commodities and the Precious Metals," and was first published—with movements up to 1886—in the Journal of the Royal Statistical Society. The commodities comprise the following, some of the more important articles being represented by two descriptions: Wheat, flour, barley, oats, maize, potatoes and rice, beef, mutton, pork, bacon and butter, sugar, coffee and tea, iron, copper, tin, lead and coals, cotton, flax, hemp, jute, wool and silk, hides, leather, tallow, palm-oil, olive-oil, linseed-oil, petroleum, soda, nitrate, indigo and timber.

The Index Numbers have been constructed in the following manner: The average prices of the 11 years 1867-77—which in the aggregate are equivalent to the average of the 25 years 1853-77—were called 100 in the case of each com-

modity and the percentage variation was calculated for each year; for instance English wheat, average 1867-77=54/6d. per qtr. equal to 100, average price in 1855=74/8d. equal to 137 (or 37 per cent. above the average point) and average price 1893=26/4d. equal to 48 (or 52 per cent. below the average point). The percentage figures of all articles in each year were added together and divided by the total number of commodities and the figure thus obtained formed the Index Number for the respective year, for instance 1893, total numbers of 4 commodities=3061, Index Number 66 or 32 per cent. below the average point. The Index Number is therefore the arithmetical mean, all articles being considered as of equal value. By the test of quantities—according to the importance of each article—the result was found to be perfectly reliable.

AUGUSTUS SAUERBECK, F.S.S.

3, MOORGATE STREET BUILDINGS, LONDON.

(AVERAGE OF 1867-1877 BEING 100.)

COMPILED BY AUGUSTUS SAUERBECK, F.S.S.

[illegible]

culated for each year; for instance (1931) equal to 100, average price in 1932 (above the average point) and average price in 1933 (below the average point). The two figures were added together and divided by two. The figure thus obtained formed the base figure for 1932. For instance in 1933, total numbers of 45 (above the average point) and 45 (below the average point) were added together and divided by two. In this way, the arithmetic mean, all articles being considered as of equal importance—according to the importance of the article—was perfectly reliable.

SAUERBECK, F.S.S.,  
DEGATE STREET BUILDINGS, LONDON.

This dotted line gives the best picture of the gradual movement of the average prices of whole periods as the fluctuations from year to year are obliterated.

ENTERED AT STATIONERS' HALL.

at first by the bulk of the filter. After admixture, a portion of liquid is filtered off again and titrated, giving the value B, the filter now used being the duplicate of the former one (cut simultaneously from the same sheet). This second filter and pulp, &c., is put back as before, water added to the original volume, and, after mixing, a third portion filtered off (through any convenient filter paper) and tested, giving the result C'. If L be the volume taken for titration in each case, and V the total volume of fluid and pulp, &c., operated on, the required percentage,  $x$ , is given by the equation—

$$x = \frac{AL \{ B(A + B) - 2AC \}}{V \{ B(A + C) - 2AC \}}$$

Another variation is obtainable by directly measuring the bulk of the filter paper by noting the water its duplicate displaces on introduction into a burette; preferably with a suction pump arrangement to eliminate air bubbles.

#### Volumetric Method of Estimating Phosphoric Acid.

A. F. Holleman. *Zeits. anal. Chem.* **33**, 185—186.

In a paper published by the author in the "*Recueil des travaux chimiques des Pays-Bas*," vol. 12, 1, he describes a volumetric method for the determination of phosphoric acid depending upon the precipitation of the phosphoric acid from a solution of a phosphate,  $M_3HPO_4$ , as silver phosphate,  $Ag_3PO_4$ , by a standard solution of silver nitrate, when sodium acetate is present to fix the nitric acid liberated by the reaction. The excess of silver nitrate is then titrated by Volhard's method with a solution of potassium thiocyanate. The method has been recently tested by van Ryn in the author's laboratory with solutions containing known quantities of calcium phosphate,  $Ca_3(PO_4)_2$ , dissolved in nitric acid, equivalent to from 94.9 to 190.0 mgrm. of  $P_2O_5$  in 50 cc. of the solution. A table is given showing that the results obtained are good, except when a considerable excess of the silver solution has been added (equal to 17.3 and 14.6 cc. respectively of one-tenth normal thiocyanate solution), the results being then too high.—H. S. P.

#### A New Method of Performing Schlösing's Process for Estimating Nitric Acid. L. L. de Koninck. *Zeits. anal. Chem.* **33**, 200—205.

FIGURE 1 shows the apparatus which is designed to simplify the process, and especially to prevent a back

Fig. 1.

rush up the delivery tube into the flask. The decomposition flask is a tractional distillation flask of from 200–300 cc. capacity. The side tube of this flask is bent upwards and attached to a small funnel by a piece of India rubber tubing which can be opened and closed by a clip. The delivery tube is of small bore and passes through a perforated enouchoupe stopper fitting into the neck of the flask. A ring of cork is slipped over this delivery tube, round which a wire is fastened to hold the small funnel firm. The delivery tube is so long that the difference of level between its upper and lower bends is from 75 to 80 cm. The lower end is constructed as shown in Fig. 2; a piece of tubing

Fig. 2.

open at both ends, 6–7 cm. in length and 7–9 mm. internal diameter is fused upon the end of the delivery tube. A cork of about 10 mm. thickness, and with four radiating grooves cut in it, is slipped over the upper part of the vertical tube. The delivery tube passes into and rests upon the bottom of a small crystallising dish, which contains enough mercury to cover the opening of the delivery tube where it is fused into the vertical tube, but not enough to reach to the cork. The dish is stood in a large vessel filled with water. The tube in which the nitric oxide is collected and measured is placed over the vertical tube, and rests upon the cork, and so does not dip into the mercury. A free communication between the water inside and outside of the tube is allowed along the grooves cut in the cork. When the gas is generated in the flask it easily breaks through the thin layer of mercury which covers the mouth of the delivery tube and rises up the vertical tube into the collecting tube. If, on the contrary, a back pressure is formed into the flask, only the mercury rises up the tube, but owing to its length it never enters the flask. This can also be provided for by a long delivery tube dipping into mercury, but in that case when the gas is evolved rapidly there is a risk of bubbles escaping at the side of the collecting tube.

Fig. 3 shows a convenient form of trough for cooling the gases to the temperature of the room, and reading off their volumes in the collecting tubes. A is a right-angled square trough made of zinc, lacquered on the inside to prevent the action of any mercury accidentally introduced. B is a lengthening of the trough at one corner to allow of the tubes being easily laid down and filled. C is a cylindrical deepening in the bottom of the trough, into which the tubes are placed to cool and to permit of the gas contained in them being read off at the atmospheric pressure. D is a small glass window for reading the volume of gas through. E is an overflow pipe to allow of a constant stream of water being sent through the trough.

In carrying out an analysis the author recommends Grandean's modification (Grandeau, *Analyse chimique appliquée à l'agriculture*) of comparing the volumes of nitric oxide yielded under the same conditions by the sample under examination and by a known quantity of a pure

nitrate. He conducts the operation in the above described apparatus as follows:—40 cc. of concentrated solution of ferrous chloride (containing 200 grms. of iron per litre) are poured into the flask, followed by 40 cc. of hydrochloric acid (sp. gr. 1.1), and the side tube is also filled with hydrochloric acid up to the funnel. The delivery tube is

Fig. 3.

then attached and the contents of the flask boiled until all the air is expelled from it. A collecting tube of 100 cc. capacity is then placed over the delivery tube, and 10 cc. of a solution of pure potassium nitrate (containing exactly 40 grms. of this salt per litre; 10 cc. of this yields from 95–100 cc. of nitric oxide) are poured into the funnel. The flame is then withdrawn to establish a slight vacuum in the flask, and the solution is then allowed to flow into the flask until the funnel is nearly empty. The funnel is then rinsed twice with 10 cc. of hydrochloric acid (sp. gr. 1.1) which is each time allowed carefully to flow into the flask. The flask is then again boiled and the nitric oxide evolved collected. The boiling is continued until bubbles of gas cease to enter into the collecting tube. The collecting tube is then put on one side and another put in its place. The sample to be analysed is then treated in the same way. As much of it is taken as will yield about the same volume of gas as the pure nitrate; and after this a second control analysis with the solution of pure nitrate is made. All the tubes are then placed in the cooling trough and the volumes of gas they contain read.

As many as eight or nine experiments may be made with the quantity of ferrous chloride here given, and still more if it be regenerated in the flask by adding some concentrated stannous chloride through the funnel. Care must in this case be taken, (1) that an excess of stannous chloride is not added, as this may lead to the formation of ammonia; and (2) that the funnel and tube are afterwards well rinsed with hydrochloric acid so as to remove every trace of stannous chloride from them. The number of tests that can thus be made is only limited by the tendency of the salts to crystallise out.—H. S. P.

*The Estimation of Nitrates by Means of the Nitrometer.*  
E. Henry. Bull. Soc. Chim. 1894, 11—12, 24—27.

THE method of estimating nitrates by the action of sulphuric acid and mercury, making use of the nitrometer, of the form Fig. 1 for liquids or Fig. 2 for solids, for the purpose of measuring the nitric oxide evolved, may give inaccurate results unless certain precautions are observed. Nitric oxide being slightly soluble in sulphuric acid, the least possible quantity of acid must be used for washing out the funnel. When restoring equilibrium at the conclusion of the reaction the level of the mercury in the tube *b* should be arranged at a little less than one-seventh below the level of the sulphuric acid in tube *a* so that there is a slight depression in the latter branch. Equilibrium is then restored by pouring small quantities of acid into the funnel and admitting them into the tube. This operation is also continued until the nitrometer has cooled down to the surrounding temperature.

A comparative experiment with a pure nitrate is recommended in order to estimate the effect of the solubility of nitric oxide in sulphuric acid of the formation of small

Fig. 1.

Fig. 2.

quantities of nitrous oxide, and of the sulphuric acid being more viscous than the water with which the tube was graduated.

For solids the form Fig. 3 is recommended as more suitable than form Fig. 2, the body to be analysed being intro-

Fig. 3.

duced into the stoppered funnel, dissolved in sulphuric acid or in a little water, and then sulphuric acid added, and the solution admitted into the tube.

The author considers it preferable to keep the pressure in the tube below that of the atmospheric pressure in order to diminish the error due to the solubility of the gas.

—J. G. W.

*Estimation of Ammonia in Ammoniacal Liquor, and in other Liquids containing Sulphur or Cyanogen, with Litmus as an Indicator.* E. Henry. Bull. Soc. Chim. 1893, 9, 1118.

TO avoid the inconvenience caused by the decolorisation of the litmus by hydrosulphuric and hydrocyanic acids—which, notwithstanding the presence of excess of alkali in the retort, come over with the ammonia and dissolve in the standard acid during the process of estimating ammonia—the author adds basic lead acetate to the ammoniacal liquor to be analysed. Fixed and volatile acids are thus precipitated.—A. G. B.

*Valuation of Zinc Dust.* O. Bach. *Zeits. angew. Chem.* 1894 [10] 291-292.

F. MEYER (*Zeits. angew. Chem.* [8], 1894); this *Journal*, August 1894), has devised a method for the valuation of zinc dust. The method now described by the author is the same in principle as that of Meyer, but does not necessitate the use of special apparatus. (See also this *Journal*, 1893, 65).

A weighed quantity of zinc dust is introduced into a glass jar of 150 cc. capacity and mixed with water; the jar is closed by means of a doubly-bored caoutchouc stopper through which two tubes bent at right angles pass. One tube dips below the surface of the liquid contained in the jar, whilst the other tube terminates just below the stopper. Within the jar there is also a small cylinder containing an excess of acid. The gas-delivery tube is connected with a flask containing 10 per cent. soda, and the evolved hydrogen is collected and measured in a burette of 250 cc. capacity divided into 0.5 cc. The particular form of burette employed is that described by Pinette (*Chem. Zeit.* 1890, 1442). The longer tube is connected with a carbonic anhydride apparatus, and the last named gas passed through the jar until the whole of the air is expelled. A burette filled with soda-lye is now connected to the gas-delivery tube, and the jar tipped so that a portion of the sulphuric acid contained in the small cylinder comes into contact with the zinc dust, and the evolution of hydrogen commences. As one burette is not of sufficient capacity to contain the whole of the evolved hydrogen from 1 gram of zinc dust, a second one must be attached, which can be accomplished without any loss if it be done at a moment when there is a pause in the gas evolution. When all the acid has been mixed with the zinc dust and the evolution of gas has ceased, carbonic anhydride is passed through the apparatus until the volume of the gas contained in the burette no longer increases, or the gas contained in the jar is driven out by filling it with water. The burettes are finally placed in a large cylinder of water, the temperature and pressure noted, and the volume of hydrogen, duly corrected, calculated as metallic zinc.—A. R. L.

*Notes on the Cupellation of Bismuth-Silver Alloys.* E. A. Smith. *Proc. Chem. Soc.* 1894 [139], 117.

THE loss of silver in the cupellation of lead-silver alloys has been the subject of a large number of experiments at various times, but comparatively few results have been published on the loss of silver in the cupellation of bismuth-silver alloys.

The present experiments were made to ascertain whether the loss of silver by cupellation was the same when varying quantities were employed with a constant ratio of bismuth in the place of lead, and also to find the loss of silver when cupelled with a gradually increasing ratio of bismuth.

The bismuth and the silver employed were specially purified.

The temperature was slightly lower than that usually adopted in the cupellation of lead-silver alloys.

Mr. Hambly concluded that, provided a constant ratio of lead and silver be employed, the loss of silver very slightly increases according to the decrease in the weight of the silver cupelled.

The author finds that a very much greater loss takes place under the same conditions when bismuth is present instead of lead, although the ratio of the loss appears to be about the same.

The results confirm the fact, already known, that an increasing ratio of lead or bismuth produces an increasing loss of silver, the loss, however, being very much greater in the case of bismuth.

As the loss of silver by volatilisation during cupellation is altogether inconsiderable, unless the temperature at which the operation has been conducted has been much too high, the loss is evidently due to the fact that silver is absorbed by the cupel.

*Quantitative Analysis of Vanadiferous Ligulite.* Prof. Kyle. U. S. Consular Rep. June 1894, 176-180.

See under N., page 738.

## ORGANIC CHEMISTRY.—QUALITATIVE.

*Pyrazolone Reactions.* R. v. Rothenburg. *Ber.* 27, 782.

BODIES of the pyrazolone class (most substance of antipyrine) containing non-substituted NH groups, give yellowish-brown to chestnut-brown colorations with ferric chloride. Silver nitrate gives precipitates of varying compositions; ammoniacal silver solutions are not reduced. Both alkalis and acids dissolve pyrazolones, but do not form hydrazines. Nitrous acid forms nitroso derivatives of yellow or orange colour, and benzaldehyde furnishes strongly coloured benzal derivatives, when the hydrogen in the CH<sub>2</sub> group is not wholly replaced. Bromine replaces hydrogen in this group. Diazo salts in alkaline solution give more or less unstable compounds. Oxidising agents exert energetic actions on pyrazolones, the complex HN.CO being usually destroyed.—C. R. A. W.

*Compounds of the Sugars with Polyhydric Phenols.* E. Fischer and W. L. Jennings. *Ber.* 27, 1355-1362.

ALTHOUGH the alcohols of the fatty series react with certain sugars, forming glucosides (this *Journal*, 1894, 167), it is found that the monohydric phenols do not. When, however, the polyhydric phenols are submitted to a treatment analogous to that already described in the case of the fatty alcohols (*loc. cit.*), compounds are obtained which differ according to the nature of the phenolic compound employed. The authors describe compounds of arabinose, glucose, and other carbohydrates with resorcinol, which are amorphous colourless compounds. The particular technical interest attaching to these compounds is, however, that they are found to give beautiful colour reactions when treated in alkaline solutions with certain oxidising agents, such as lead peroxide, mercuric oxide, and silver oxide. The most beautiful of these reactions is that with Fehling's solution, which, although not quite so delicate and somewhat less convenient than Molisch's reaction (*Monatsh. chem.* 7, 198), is recommended as a confirmatory method supplementary to the latter. The method of carrying out the test is as follows:—To about 2 cc. of the dilute aqueous solution of the substance to be tested, 0.2 gram of resorcinol is added and the mixture saturated with gaseous hydrochloric acid at 0°. If the quantity of carbohydrate present is small, the test is now allowed to remain at the ordinary temperature for 12 hours, but if, on the other hand, the amount of carbohydrate is considerable, one hour suffices. The liquid is diluted with water, an excess of caustic soda added, and it is warmed with Fehling's solution, of which latter only a few drops are taken when the amount of carbohydrate is small. A reddish-violet very characteristic coloration ensues; it is fugitive after a time when the liquid is highly diluted. Insoluble carbohydrates such as starch are triturated with water, and after the addition of resorcinol the cooled mixture is saturated with gaseous hydrochloric acid. The reaction has been found to answer for the detection of small quantities of saccharose, lactose, maltose, dextrin, gum, glycogen, starch, and cotton wool, besides being available for the simpler sugars (pentoses and hexoses); normal urine also exhibits the reaction.

Compounds with other phenols are described in the paper, which have only a purely scientific interest.—A. R. L.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*The Employment of "Micro-Chemical" Reagents in Analytical Chemistry. First Communication.* W. Lenz. *Zeits. Anal. Chem.* **33**, 193—204.

*The Estimation of the Ethereal Oils, particularly in Cloves and Mace.*—The author having known for some time that a solution of equal parts of water and crystallised sodium salicylate was an excellent clarifying and preservative reagent for microscopic preparations, and having also noticed the peculiar solvent properties of this solution upon various ethereal oils, especially of oil of cloves, was led thereby to use it in the analytical determination of oil of cloves. He first of all describes his method for extracting ethereal oils by water alone, which is as follows:—From 10—20 grms. of the material to be examined are placed in a tubulated retort of about 250 cc. capacity, the long neck of which is bent to a right angle at about the middle. Enough water is added to the material to make a thin "slurry," the neck of the retort, which ascends to the bend and then dips downwards, is attached to a condenser, and steam is then passed through the mixture in the retort by means of a tube passing through the tubulus. The contents of the retort are at the same time heated by a gas flame so regulated that the volume of liquid is kept constant. The particles of material may be prevented from being carried up the sides of the retort by the addition of about 10 cc. of pure olive oil to the contents of the retort. The distillation with steam is maintained until the distillate is tasteless and odourless, and is without a trace of oily particles passing over. The volume of distillate in the author's experiments was about 500 cc. The whole of this can be collected in a separating funnel. Sodium chloride is added to it nearly to saturation (150 grms. NaCl to 500 cc. of distillate), and it is then shaken repeatedly with ether until the residual liquid, after expelling the ether, has no smell of the ethereal oil sought for. The author found three shakings with ether—first with from 50—100 cc., then with 50 cc., and again with 50 cc.—quite sufficient. To the ethereal solution sufficient fused calcium chloride (about 20 grms.; so much should be added that the particles of calcium chloride are only bound together and not liquefied by the water extracted) and it is then allowed to stand at least three, and better, four days. The clear water-free ethereal solution is transferred to a tared flask, and the flask, containing the calcium chloride, rinsed out with water-free ether. The ether is then expelled at a temperature not exceeding 30° C. by passing a stream of dry air through the flask until the smell of ether is gone and the weight of the flask remains constant. When necessary, the evaporation of the ether may be done in a dark place, or, instead of air, a stream of dry carbon dioxide or hydrogen, &c., may be used.

The author then describes the results he has obtained by using an exactly neutralised solution of equal parts of sodium salicylate and water, instead of water alone, for extracting the ethereal oils from cloves. He used 10 grms. of powdered cloves in each experiment, and extracted the oils from this amount, in one series using water alone and in another the sodium salicylate solution. The neutralisation of the sodium salicylate is necessary because the commercial salt generally contains a trace of free salicylic acid, which is volatile and would pass over with the ethereal oils. The percentage of eugenol (the actually valuable constituent of oil of cloves) in the oils obtained was determined by separation as benzoyl-eugenol according to Thoms' method (*Zeits. anal. Chem.* **30**, 78).

	Oils.		Eugenol.
	Per Cent.	Per Cent.	
10 grms. of cloves distilled with water yielded—	(1) 18.00	14.91	
	(2) 17.49	14.19	
10 grms. of cloves distilled with sodium salicylate yielded—	(1) 20.20	16.17	
	(2) 18.70	16.70	

From this it is seen that the salicylate distillation yields nearly 2 per cent. more oil and more than 2 per cent. more eugenol than the water distillation. The oil from the water distillation contained 79.44 per cent. of eugenol, and the oil from the salicylate distillation contained 84.52 per cent. eugenol. Thoms (*Pharm. Zeitung*, **35**, 609) found from 76.8 to 90.64 per cent. of eugenol in various samples of oil of cloves. Schimmel and Co. have informed the author that they find that a good oil of cloves contains about 80 per cent. of eugenol. They also told him that the yield of oil from 100 kilos. of Amboina cloves was from 19—20 kilos. The perfect drying of the ethereal extract is very important in the above process. Although the amount of total oil varied somewhat considerably, the percentages of eugenol showed more agreement, but the highest percentages of eugenol, both in the case of the water distillation and salicylate distillation, were obtained when the ethereal solution had stood four days instead of three days with calcium chloride.

In order to explain the action of the sodium salicylate, a series of experiments were next made on the extraction of the ethereal oil of mace (which is almost insoluble in sodium salicylate) from powdered mace. 10 grms. of the sample were distilled with water, with sodium salicylate solution, and further, with 50 per cent. solutions of potassium acetate and calcium chloride respectively, in order to show if the larger yield of oil were not obtained on account of the increased temperature, due to the raising of the boiling point above 100° by the salts in solution. The results obtained were as follows:—

	Per Cent. of Oil of Mace.
Water distillation .....	6.70
Sodium salicylate distillation .....	8.44
Potassium acetate " .....	6.71
Calcium chloride " .....	6.77

The oil from the salicylate distillation was found to contain only a very minute trace of salicylic acid. It is seen, therefore, that in this case also a much larger yield of oil is obtained when sodium salicylate is used. This result must therefore be ascribed to the solvent action of this reagent upon the plant tissue and cells containing the ethereal oils, which thereby sets free the oil and allows it to be carried over by the steam. It is this same solvent action upon tissue which makes sodium salicylate useful in microscope work as a clarifying medium.—H. S. P.

*Lard.* Samelson. *Zeits. anal. Chem.* 1894, **33**, 189—192

THE author finds that the Welman reaction is unreliable as an indication of adulteration with cotton-seed oil, as he obtained a faint blue reaction with undoubtedly pure lard. He also found this reaction less sensitive than the Beechi nitrate of silver test. Beechi's test, it is however admitted, does not react with superheated cotton-seed oil. Gautier's sulphuric acid test he also finds unsatisfactory for detecting admixture with vegetable oils. He concludes that no reliable test for vegetable oils in lard, is known, and considers that the iodine absorption number is the thing most to be depended upon as an indication of adulteration in lard.

—H. S. P.

*Estimation of Fat in Cheese.* S. Bondzyski. *Zeits. anal. Chem.* **33**, 186—189.

THIS is an adaptation of the Werner-Schmid method of fat estimation in milk to testing cheese. A quantity of the finely rubbed-up cheese (the weight that should be taken is not stated) is brought into a glass tube such as is used in the Werner-Schmid method of estimating fat in milk, and 20 cc. of hydrochloric acid of sp. gr. 1.1 are added, and the contents of the tube are warmed gently over wire-gauze until the cheese dissolves and the melted fat rises in a layer to the surface. The tube is then cooled and about 30 cc. of ether are added. The fat dissolves at once in the ether. The contents of the tube are then allowed to stand at 40° C. until the acid solution and the ethereal layer have become sharply separated. The volume of the ethereal solution

is now read, 20 cc. of it are then pipetted off into a tared Erlenmeyer flask, and the fat contained in it weighed after expelling the ether. In comparison with the Soxhlet extraction method, this process gave very good results. In two Erlenmeyer flasks the author found 31.5 per cent. and 32.6 per cent. respectively of fat.—H. S. P.

*Optical Titration of Mannitol.* J. A. Muller. Bull. Soc. Chim. **11**—**12**, 1894, 329—336.

In order to obtain an optical method of assaying wines for mannitol, this sugar was isolated from various natural wines containing it, and carefully compared with mannitol from manna; the identity of the two was clearly demonstrated. Solutions of mannitol in water are inactive towards polarised light, but become active on further addition of certain salts, such as arsenates and borates, or the free acids corresponding therewith. A saturated borax solution gives, with a given quantity of mannitol, a rotatory action varying with the temperature; with 2 to 3 grms. of mannitol per 50 cc. an increase of temperature gives an augmentation in rotation of about 0.1 per degree. Having due regard to this correction, the following table may be used to determine the mannitol present in 50 cc. of fluid saturated with borax:—

Polarimetric Deviation.	Mannitol in 50 Cc.	Polarimetric Deviation.	Mannitol in 50 Cc.
0.0	Grms. 0	0.0	Grms. 1.000
1.0	0.048	10	1.080
20	0.007	20	1.160
30	0.146	30	1.240
40	0.195	40	1.324
50	0.244	50	1.413
1.0	0.293	4.0	1.502
10	0.344	10	1.613
20	0.393	20	1.726
30	0.443	30	1.843
40	0.500	40	1.963
50	0.552	50	2.106
2.0	0.625	5.0	2.250
10	0.688	10	2.335
20	0.751	20	2.430
30	0.814	30	2.571
40	0.876	40	2.742
50	0.958	50	2.975

These figures are apt to be modified by the presence of certain kinds of inactive organic matter, more especially glycerol. In applying them to wine, the liquid should be precipitated by basic lead acetate, and the filtrate treated with sulphuretted hydrogen, and concentrated, preferably only to such an extent that the mannitol present does not exceed 2.5 to 3 grms. per 50 cc. Sugars capable of fermentation, if present in the original wine, must be previously fermented away.—C. R. A. W.

*Conicine and Nicotine.* G. Hent. Arch. der Pharm. **231**, 376.

CONICINE is differentiated from nicotine by its odour, its crystalline hydrochloride, and by the greater difficulty of obtaining with it precipitates with the ordinary reagents. Conicine instantly turns an alcoholic solution of phenolphthalein red, whilst nicotine does not do so. The author uses this reaction as a means of estimating these two alkaloids when mixed. The mixture is titrated with normal

sulphuric acid in the presence of phenolphthalein. As soon as the red coloration disappears (showing the neutralisation of the conicine) the titration of the nicotine is effected with litmus as indicator. L. T. F.

*Acetone Its Valuation.* E. Kopp and E. Grandmougin. Bull. Soc. Ind. Mulhouse, 1894, 112—116.

See under IV., page 729.

*Notes on the Examination of Beeswax.* Lyman F. Kehler. J. Franklin Inst. **137**, 1894, 58.

See under XII., page 745.

## ANALYTICAL AND SCIENTIFIC NOTES.

*Compounds of Hydrogen Cyanide with the Anilides of the Sugars.* W. v. Miller, J. Plochl, and R. Strass. Ber. **27**, 1281—1296.

CONDENSATION products of the sugars with aniline and paratoluidine were first prepared by H. Schiff (Annalen, **140**, 123; **154**, 34), but they were only obtained in the crystalline form some years later by Sorokin (J. Prakt. Chem. [2], **37**, 304).

The authors have discovered the fact that the anilides of the sugars, of which glucose anilide—

is the prototype, combine with hydrogen cyanide. *Anilido-glucose cyanide*,  $\text{C}_6\text{H}_5\text{OH} \cdot \text{CH}_2\text{OH} \cdot \text{CH}_2\text{OH} \cdot \text{CH}(\text{CN})\text{NHC}_6\text{H}_5$ , is obtained by adding an excess of aqueous hydrocyanic acid to a solution of glucose anilide at the ordinary temperature, and allowing the mixture to remain in a cool place. Needle-shaped crystals separate out after a while; the compound melts at 166—168°. *Toluidogluco-cyanide* melts at 128°; *anilidogalacto-cyanide* melts at 138°; *toluidogalacto-cyanide* melts at 145—146°; and *anilidoleuco-cyanide* melts at 131°.

The hydrazone and oxime of glucose were found, under none of the conditions tried, to combine with hydrogen cyanide.—A. R. L.

*The Influence of Moisture on Chemical Action.* H. Breerton Baker. Proc. Chem. Soc. 1894 [139], 111—113.

SINCE the publication of a former note (this Journal, 1893, 553), further investigations of the actions described, have been made. Sulphur trioxide does not combine with highly purified lime; but a trace of moisture brings about vivid incandescence. Dry copper oxide is also without action on sulphur trioxide. Purified and dried lime does not decompose dried ammonium chloride, which may be sublimed from the mixture without evolving any ammonia. Purified and dried nitric oxide gives no brown fumes with dried oxygen, but a trace of moist air causes them to appear at once. A mixture of purified and dried hydrogen and chlorine can be exposed to daylight for four days without more than three-fourths of the gases combining. Ammonium chloride, heated in a vacuum in a soft glass tube, leaves a residue of ammonia gas; but when dried and heated in a hard glass tube, no gaseous residue is obtained. Separation of dried ammonia and hydrogen chloride gases takes place when plates with opposite electrical charges are introduced into the mixture though the action cannot be electrolytic, since discharge is, under the circumstances, impossible. Similar separation was noticed with air and with a mixture of dried hydrogen and oxygen. Electric discharge, when not of high tension, will not pass in dried gases; but the high tension discharge does pass, and renders it possible for the low tension discharge to pass afterwards. With regard to the influence of moisture, it appears that what holds for chemical combination holds also for electrical discharge, and that there is great significance in the apparent similarity in the two cases.

In the discussion which followed, Dr. Armstrong spoke of Mr. Baker's results as of great value and as calculated

to convince all of the important influence exercised by moisture in promoting very many chemical changes; he had long been satisfied that the presence of an electrolyte was essential to every chemical change, and that water was of service because it gave rise to an electrolyte. It was now important to ascertain whether other substances besides water could condition the formation of electrolytes and thus co-operate in producing change, and to determine what their nature was; probably water was one of very few substances able to act in this manner, if indeed it were not the only one. In the case of hydrogen and chlorine, there was reason to think, as Mr. Shenstone had indicated, that some substance other than water was also essential to the occurrence of change.

He was glad to hear Mr. Shenstone say that he was not yet satisfied that pure oxygen can be ozonised; his statement that more ozone was obtained from dried oxygen might be regarded as evidence that water influenced its formation; the amount of ozone finally obtained depended on the amount destroyed as well as on the amount originally formed, and if both its formation and destruction were influenced by moisture, it might well be that one action was more directly influenced than the other when but very little moisture was present. If the destruction took place the less rapidly the less water present, the amount finally obtained would be the greater the more carefully the oxygen was dried.

Regarding the decomposition of ammonium chloride by heat, although moisture would promote its decomposition, the absence of moisture would not have the effect of making it a stable substance at all temperatures; it might be expected that, if dry, it would decompose when heated sufficiently, but would not dissociate; in other words there would be no re-formation of ammonium chloride under such conditions.

## New Books.

**HANDWÖRTERBUCH DER PHARMACIE.** Herausgegeben von A. BRESTOWSKI. Wien und Leipzig: Wilhelm Braumüller. K. u. K. Hof- und Universitäts Buchbändler. 1893. London: H. Grevel & Co., 33, King Street, Covent Garden.

VOLUME II. of this Dictionary is now continued with Parts 15 and 16, which have just appeared. Part 15 commences with the unfinished subject "Mineralwasser," and ends with that of "Niederschlag," which is continued into and ended in Part 16. Part 16 concludes with an article on "Pasta," or Pastes, which will be continued into Part 17.

**TABELLÄRISCHE UEBERSICHT ÜBER DIE KÜNSTLICHEN ORGANISCHEN FÄRBESTOFFE UND IHRE ANWENDUNG IN FÄRBEREI UND ZEUGDRUCK.** Von Dr. ADOLF LEHNE. Herausgeber der Färber-Zeitung. Fünfte Lieferung. Berlin: Verlag von Julius Springer. 1894. London: H. Grevel & Co., 33, King Street, Covent Garden.

This work has now reached the issue of Part V., containing, besides all the requisite tests of the dyes described, also the methods of application, solubilities, powers of resistance, &c., with a column containing beautifully dyed and printed illustrative specimens.

Part V. commences with "Malachite green" and ends with Cyanosine B. (This Journal, 1894, 429.)

**WATER ANALYSIS.** A Practical Treatise on the Examination of Potable Water. By J. ALFRED WANKLYN and E. T. CHAPMAN. Ninth Edition. By J. ALFRED WANKLYN. London: Kegan Paul, Trench, Trübner & Co., Limited. 1894. 5s.

A NINTH edition of this work is now issued, the eighth having become exhausted.

**ANALYSES OF TWELVE THOUSAND PRESCRIPTIONS.** Compiled by W. MARTINDALE. Joint Author of the Extra Pharmacopœia. London: H. K. Lewis, 136, Gower Street, W.C. 1894. 2s. 6d.

THIS little work is dedicated to the General Council of Medical Education and Registration, of the United Kingdom. The Index of the seventh edition of the Extra Pharmacopœia was the basis on which the analyses were compiled, and the last column of figures indicates the pages of the work referred to. The figures are statistics of the frequency of use, not only of the official preparations (printed in italics), but also of unofficial medicaments, so that if carefully examined, they indicate not only the preparations which might be deleted should the Medical Council think fit, but also those which might be made official, *ceteris paribus*, on account of their being frequently prescribed.

The analyses are of the last 12,000 medical prescriptions dispensed antedated to the 1st ultimo, in six pharmacies in typical positions in the United Kingdom, 2,000 at each centre. There are 2,000 from the compiler's own pharmacy, and 10,000 from the pharmacies of friends in Aberdeen, Bournemouth, Carlisle, Cork, and Oxford.

**DIE CHEMISCHE INDUSTRIE AUF DER COLUMBIEN WILTAUSSTELLUNG ZU CHICAGO UND IN DEN VEREINIGTEN STAATEN VON NORD-AMERICA IM JAHRE 1893.** Bericht dem Königlich Preussischen Staatsminister und Minister der Geistlichen, Unterrichts- und Medicinalangelegenheiten, Herrn Dr. Bosse, erstattet von Dr. OTTO N. WITT, Professor der Chemischen Technologie, an der Königl. Technischen Hochschule zu Berlin. Berlin: R. Gaertner's Verlagsbuchhandlung. Hermann Heyfelder. 1894. London: H. Grevel & Co., 33, King Street, Covent Garden. Price 5s.

Two volume, bound in cloth and containing 148 pages of subject-matter, preceded by a short preface and table of contents. An introduction describing the occasion, and the various reasons for, and the nature of the great World's Fair at Chicago, more especially with reference to the chemical industries. The following departments and subjects of that portion of the exhibition devoted to the chemical industries, are treated of and generally described. I.—Fuel and Heat-producing Agents at the Columbian Exhibition and in the United States. A. Natural Gas and Petroleum. Refining Petroleum. B. Natural Products more or less related to Petroleum. C. Coals and Coke. D. Wood as Fuel. II.—Chemical Industries involving Inorganic Chemistry. A. The Raw Materials of the Acid and Alkali Industries. B. Acids and Alkalis. C. Artificial Manures. D. Glass. E. Glass and Pottery. F. Chemical Apparatus. G. Chemical Preparations. III.—Chemical Industries involving Organic Chemistry. A. Industries relating to Dry Distillation. B. The Manufacture of Dye-stuffs. C. Dyeing and Calico Printing. D. Textile Fibres. E. Fats and Soaps.

**NATURE'S HYGIENE.** A Systematic Manual of Natural Hygiene, containing a detailed Account of the Chemistry and Hygiene of Eucalyptus, Pine, and Camphor Forests, and Industries connected therewith. By C. T. KINGZETT. Fourth Edition. London: Baillière, Tindall, and Cox, King William Street, Strand. 1894. Price 10s.

THE third edition of 1888 (this Journal, 1888, 459) having been for some time out of print, the author has now brought out a new one. This fourth edition is the result of a very careful revision of the third, and also of the addition of a chapter on some new developments of bacteriological science (in relation to the subjects of Phagocytosis and Immunity). A further chapter on Alimentation and Foods has been added, and, moreover, the results of the author's recent investigations of the Chemistry of the Aerial Oxidation of Turpentine and other Essential Oils. The author acknowledges the help rendered by his assistant, Mr. D. Homfray, B.Sc.

THE LABORATORY GUIDE. A Manual of Practical Chemistry for Colleges and Schools, specially arranged for Agricultural Students. By A. H. CURRIE, M.A., F.R.S. Seventh Edition, revised. London: Gurney and Jackson, 1, Paternoster Row. 1894. Price 6s. 6d.

8vo. volume, bound in cloth, and containing Prefaces, Table of Contents, and 283 pages of subject-matter, illustrated with 22 wood engravings.

An alphabetical index of subjects, and a list of apparatus required by the student in following the course advocated in the work, complete the same.

It is announced that, besides a careful revision of the sixth edition, this, the seventh, contains an additional Lesson on Soils, which is now introduced in Part I., whilst certain improved Quantitative Methods appear in Part III. Three processes, now lapsed and obsolete, have been allowed to disappear from the volume: these are the citric acid method for determining phosphorus pentoxide, the old process of extracting fat from milk residues, and the sulphuric acid method for the isolation of indigestible fibre.

The text is sub-divided as follows:—I. Chemical Manipulation. Preparations and Experiments. II. Qualitative Analysis. III. Quantitative Analysis. Analysis of Manures. Analysis of Soils, Waters, and Foods.

The volume is strongly bound in a good waterproof cover.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### CANADIAN TARIFF CHANGES—continued.

(This Journal, June 1894, p. 672.)

Articles.	Rates of Duty.
<i>Sugar, Syrups, and Molasses.</i>	
All sugar above No. 16 Dutch standard in colour, and all refined sugars and molasses, N.O.P., of whatever kinds, grades, or standards.	Per lb. 1½ cent.
Sugars, syrups, and molasses of all kinds, N.O.P., the product of the sugar-cane or beetroot, N.E.S., and all imitations thereof or substitutes thereof.	" 1 cent.
Glucose or grape sugar, glucose syrup and corn syrup, or any syrups containing any admixture thereof, a specific duty of.	" 1 cent.
Sugar candy, brown or white, and confectionery, including sweetened gums, candied peel, and pop-corn.	35 <sup>+</sup> ad val.
Liquorice paste, and liquorice in rolls and sticks.	20 <sup>+</sup> ad val.
Molasses produced in the process of the manufacture of cane-sugar from the juice of the cane, when imported in the original packages from the district where produced in the country where the cane was grown, and which has not been subjected to any process of treating or mixture after leaving the country from which originally shipped. The packages in which imported when of wood to be free.	
(a.) Testing by polariscope, 49° or over, a specific duty of.	Per gall. 12 cents.
(b.) When testing by polariscope, less than 40° and not less than 35°, a specific duty of.	" 1½ cents.
For each degree or fraction of a degree less than 40°.	Per degree additional 1 cent.

#### CANADIAN TARIFF CHANGES—continued.

Articles.	Rates of Duty.
<i>Small Arms.</i>	
Fertilisers, compounded or manufactured.	10 ad val.
Fireworks.	25 ad val.
Gun, rifle, and pistol cartridges, cartridges cases of all kinds and materials, percussion caps and gun wads of all kinds.	30 ad val.
Blasting and mining powder.	Per lb. 2 cents.
Cannon, musket, rifle, gun, and sporting powder and canister powder.	" 3 cents.
Nitro-glycerine, gun powder, and nitre, and other explosives.	" 4 cents.
Photographic dry plates.	30 ad val.
Oil, sperm, whale and other fish-oils, and all other articles the produce of the fisheries, not specially provided for.	20 ad val.

The following are free:—Acids used for medicinal, chemical, or manufacturing purposes not specially provided for in this Act; alum in bulk only; aluminium and its salts; ambergris; ammonia and its salts; aniline salts, and dyes in bulk, and alizarine; aniline oil, annatto; antimony; arsenic; asphalt; bismuth; blood, albumen, and tannic acid; bones, emude.

#### UNITED STATES.

##### Customs Decisions.

Hydrated oxide of iron is dutiable at 25 per cent. *ad valorem* under paragraph 76, N.T.

Magnesite bricks of the kind used in furnaces for the smelting of lead ores are dutiable at 1.25 dols. per ton under paragraph 93.

A compound known as encalyptol camphyline is dutiable at 25 per cent. *ad valorem* under paragraph 76, N.T.

Coffee substitute put up in papers and in tins, and composed of a mixture of chicory-root, beet-root, oil, syrup, and other ingredients, is dutiable at 1½ cents per pound under paragraph 321, as substitutes for coffee.

Crude olein or oleic acid, a fat oil of animal origin, chiefly and commonly used in soap making, and in its condition as imported fit only for such uses, is entitled to free entry under paragraph 599.

### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

#### IRON MINING IN NORTHERN SPAIN.

Mr. Victor de Larrea, Acting British Consul at Bilbao, in the annual commercial report of that consular district for the year 1893, gives the following particulars of the mining of iron ore in Spain, special reference being made to the Biscay district:—

There is no doubt that in Spain there yet exist abundant deposits of minerals, particularly of iron ore, which being far inland remain unworked, partly from want of easy means of conveyance and partly from want of enterprise.

The total number of the mines registered in Spain is over 15,000, of which only about 2,000 are worked.

The province of Biscay, however, still gains very considerable profits from its rich iron ore mines, as may be deduced from the fact that in 1893 of a total production in Spain of 5,497,540 tons, the consular district of Bilbao was responsible for 4,918,650 tons; whilst in 1892, out of a total for Spain of 5,405,170 tons, the consular district of Bilbao furnished 4,573,560 tons.

The exportation of iron ore from Bilbao to the United Kingdom in 1893 was over 3,000,000 tons, and, as the total foreign import of iron ores into the United Kingdom was

1,065,563 tons (3,624,083 tons from Spain and 441,780 tons from other countries), it appears that shipments of Bilbao ores made up 84 per cent. of the importation from Spain and 75 per cent. of the total foreign importation of iron ores in the United Kingdom in 1893; and, calculating the yearly production of iron ores in the United Kingdom to be 14,000,000 tons, it would appear that Bilbao supplies about the fifth part of the iron ores yearly consumed in the United Kingdom.

With regard to the output of iron ore in Biscay, and the very considerable quantities exported for the last 16 years at the rate of 3,000,000 tons to 4,000,000 tons per annum, the question has often been raised as to how long the mines may be expected to continue this yield. This is certainly a matter very difficult to forecast, but it may be observed that the number of mines yielding good quality ores is becoming smaller, with the inevitable result that in the course of time the exportation will decrease and the quality deteriorate.

The forms of the iron ore deposits in the province of Biscay are simple and practically on the same geological horizon, a circumstance which adds materially to a ready comprehension of them. They are bedlike in form generally, and appear with an exposed surface, or simply covered by shale, or overlaid by heavy beds of limestone.

The deposits are all quarried, and for quarrying operations the explosives used are powder and dynamite.

The number of men employed in the working of the iron ore mines in the province of Biscay is estimated at 12,000. —(No. 1398, *Foreign Office Annual Series*.)

#### OPIMUM ADULTERATION IN CHINA.

The following note on the subject of opium adulteration is taken from the commercial report for 1893 of Mr. R. W. Hurst, Her Majesty's Consul at Tientsin:—

Sesamum seed cake is now quite out of use for opium adulteration, being supplanted by "Tientsin" cake, a repulsive preparation of boiled-down skins and all kinds of refuse of a "gelatinous" nature, to which, in boiling, has been added opium pod, stalk, husk, &c.—in fact, anything that would impart to it the taste or smell of opium.

It is used for the adulteration of opium in increasing proportions; last year two or three parts of the cake to seven or eight of opium; this year three or four parts of the cake to six or seven parts of opium. The price in 1892 averaged from 17 dols. per cwt. to 25 dols. per cwt.; this year 54 dols. per cwt. to 42 dols. per cwt. It is imported under the name of "medicinal cake" mostly by foreign vessels, but to some and to an increasing extent also by junk. The poorer classes buy a mixture of nearly equal parts of opium and "Tientsin cake."

The cake is sold by the dealers with each chest of opium sold, the adulteration being done by the wholesale dealers in prepared opium, and again by the retail dealers.—(No. 1401, *Foreign Office Annual Series*.)

#### GENERAL TRADE NOTES.

##### PETROLEUM DISCOVERIES IN THE CAUCASUS.

The *Bulletin du Musée Commercial*, in its issue for the 2nd June, states that discoveries of petroleum were made some time ago in the Northern Caucasus, and especially in the district of Groznoje; later soundings have given very remarkable results.

During the month of October 1893 soundings were made in this district to a depth of 440 ft.; the results obtained were very good as regards quality and quantity.

According to the *Journal de la Chambre de Commerce de Constantinople* this experiment was an innovation, for hitherto wells of little depth, like those sunk at Bakn, had been made.

The yield of the wells referred to was, for a period of four days, 200,000 pounds, or about 3,280 tons. This yield would probably have been larger if, owing to the manner

in which the pipes were connected, a large quantity of water coming from the upper beds of soil had not mixed with the naphtha.

The product was gathered in a reservoir built in the ground, and representing a capacity of 10,000 tons; its further treatment showed that it contained a greater proportion of lighting oil and a smaller proportion of residues than Bakn petroleum.

More recently two other wells have been opened by another firm, with diameters of 20 and 9 ins., and new soundings are now being suggested. Carriage will be effected by the Vladikavkaz-Petrovsk railroad.

##### THE MATCH MONOPOLY IN FRANCE.

The *Economiste Français* for the 2nd June publishes the following particulars of the results of the match monopoly of 1893, taken from the report of the general direction of State manufactures. There were manufactured 28,422,242,550 matches (27,006,377,050 of wood and 1,415,865,500 of wax) ready to be delivered for sale. The cost of manufacture was 3,394,270 francs; the average cost for manufacture was therefore 119.42 francs per million matches. The general cost price of the matches ready for sale comes to 194.59 francs per million matches, which are sold wholesale for about 900 francs. The regie expended last year 6,349,006 francs. It sold wholesale or into the warehouses 29,340,192,390 matches, corresponding to receipts aggregating 25,874,542 francs. The profit on the manufacture of matches was therefore 19,500,000 francs, to which should be added the increase in the capital of the regie, which gives a net profit of 20,072,456 francs.

##### THE MINERAL STATISTICS, 1893.

The official mineral statistics for the year 1893 have just been completed and issued by the Home Office. Taking the returns in alphabetical order, we find the quantity of alum clay or bauxite was 8,740 tons, as against 7,322 tons in 1892—entirely raised in Antrim, Ireland. Of aluminium there are only two makers in the United Kingdom, and no details are procurable of their production. Alum shale is raised in Yorkshire only, from a bed lying between two seams of the Stanley Main bed of coal, and the quantity was 2,115 tons, against 2,922 tons in 1892. Antimony ore is mined in Cornwall, but none was raised last year, and only very small quantities in previous years. Arsenic is produced in Cornwall and Devonshire, the quantity last year being 5,976 tons, as against 5,114 tons in 1892. Of arsenical pyrites the quantity was 3,036 tons, as compared with 4,497 tons. The quantity of barytes (mainly sulphate) was 22,343 tons, against 24,247 tons in 1892, the principal districts being Northumberland, Shropshire, and Ireland. Of bismuth there is only one producer, and no returns are given. Bog ore, chiefly used for gas-purifying, is exclusively obtained in Ireland, the quantity last year being 10,747 tons, against 15,363 tons in 1892. Of clays, not including ordinary clay, the quantity was 3,065,208 tons, against 3,103,852 tons in the previous year. Of coal, the total quantity mined last year was 164,325,795 tons, as compared with 181,786,871 tons—the decrease being attributable, no doubt, to the coal strike. There is only one mine raising cobalt and nickel ore, and it is closed at present. Copper-mining is an industry which the report says is "rapidly decreasing in Britain," the output having fallen from 210,000 tons in 1863 to a little over 5,000 tons in 1893, and 6,265 tons in 1892. Our imports of copper come from various parts of the world, but, as for many years past, principally from Spain and the United States, the latter country sending 37,761 tons, and Spain 48,709 tons last year. The total quantity of copper obtained by smelting in the United Kingdom last year was 69,810 tons, against 78,346 tons in 1892. Of fluorspar the quantity was 215 tons, compared with 171 tons. Of gold ore there was raised 4,489 tons, yielding gold valued at 7,657*l.*, as against 9,990 tons and 9,168*l.* in 1892. All the mines are at Dolgelly. Of gypsum the output was 143,486 tons, against 147,540 tons in 1892. The aggregate quantity of iron ore raised last year was 11,203,476 tons, against 11,312,675 tons in the previous year. The quantity of iron ore imported was

4,065,864 tons, compared with 3,780,503 tons in 1892. It is of some interest to note that there were 327 furnaces in blast in 1893, making 6,976,940 tons of pig iron from 16,620,653 tons of ore, and using 13,806,728 tons of coal. Of iron pyrites the quantity raised was 15,837 tons, against 13,967 tons the year before. The quantity of jet produced was 888 lbs., as against 929 lbs. in 1892, the output of this mineral having decreased greatly since 1886. Our production of lead ore was 10,808 tons, yielding 29,698 tons of lead, as compared with 10,024 tons of ore and 29,510 tons of lead in 1892. The principal districts are Durham, the Isle of Man, Flintshire, and Derbyshire. Our imports of lead and lead ore were 2,857 tons, against 18,217 tons in 1892, and our exports of British pig lead 29,735 tons, against 39,178 tons, and of lead sheets, piping, &c., 19,366 tons, against 18,984 tons in 1892. These were in addition to 18,836 tons of foreign pig and sheet lead last year, against 15,613 tons in 1892. Only one British mine yields lignite, the quantity being 3,264 tons, against 4,217 tons in 1892. Manganese ore figures for 1,336 tons, compared with 6,078 tons in 1892, whereas our imports of this mineral last year were 121,773 tons. Of ochre, amber, &c., our production was 10,534 tons, against 12,131 tons in 1892. Oil-shale was raised, chiefly in Scotland, to the total of 1,956,520 tons, against 2,089,937 tons in the previous year. Lindlithgowshire and Edinburghshire are the principal districts. Of petroleum (found only in North Staffordshire on a scale worthy of being recorded) we produced 26 tons, against 18 tons in 1892. The total of phosphate of lime was 3,300 tons, as against 12,200 tons in 1892, the increasing imports of cheaper foreign materials having serious effects upon this Bedfordshire and Cambridgeshire industry. Our output of salt last year was 1,924,029 tons, as compared with 1,956,524 tons in the previous 12 months. Of silver, all produced from argentiferous lead ores, the quantity was 274,160 oz. Of slates the quantity was 138,993 tons, against 118,241 tons in 1892. Sodium is made by four firms, but no returns are given. Strontia sulphate is dug from shallow pits in Gloucestershire and Somersetshire, the quantity being 5,812 tons, as against 5,066 tons in 1892. Of tin ore we produced 13,688 tons, against 11,355 tons, the yield of tin being 8,837 tons, as compared with 9,270 tons in 1892. Our imports of tin were 671,162 cwt., compared with 589,365 cwt. the previous year. One mine only, in Cornwall, yields uranium, the quantity being 25 tons, against 37 tons in 1892; and one mine only, also in Cornwall, raises wolfram, last year's output having been 22 tons, against 125 tons in 1892. Of zinc ore our output was 23,754 tons, yielding 9,284 tons of metal, against 23,880 tons and 9,349 tons respectively in 1892.—*Ironmonger.*

#### THE ENGLISH AND GERMAN CHEMICAL INDUSTRIES.

The report on technical education presented in July, 1891, to the Manchester Whitworth Institute by the deputation which was appointed by the council of the Manchester Technical School to visit the technical schools and institutions in England and on the Continent, was remarkable for the statements made therein respecting the lack of efficient technical instructors in certain of our industries. It added:—"The forethought of Continental Governments in this respect (viz., the supply of properly qualified teachers), may be compared, in several very interesting and striking directions, with our own want of provision. For instance, when this council has required the services of a competent instructor for the chemical, dyeing, and calico-printing classes, it has been found indispensable to engage one who has been trained in a Foreign Technological Institution for that important section of its work; and it is well known that many of our leading firms experience almost insuperable difficulty in finding, amongst our own countrymen, that combination of scientific with practical knowledge, by which alone they can hope to compete with their Continental rivals."

This is surely very severe condemnation of our want of system in training competent teachers and assistants for the chemical trade of this country. Indeed, it is partly due to this negligence that Germany has succeeded in building up a very extensive trade in chemicals and chemical compounds of all descriptions.

If we take the export trade of this country in alkali, bleaching materials or preparations, chemical manure, mineral preparations, &c., we shall find that it has not made that progress which we might have expected under proper conditions. The appended table shows the values of our exports in the years named—

	1888.	1891.	1892.
Alkali .....	£ 1,638,770	£ 1,512,000	£ 1,087,206
Bleaching materials or preparations .....	615,081	564,113	506,976
Manure (chemical) .....	1,849,035	2,000,170	2,070,216
—	—	—	—
	1891.	1892.	1893.
Alkali .....	£ 2,035,112	£ 2,119,791	£ 1,858,157
Bleaching materials or preparations .....	522,445	508,619	551,167
Manure (chemical) .....	2,111,370	2,137,811	2,312,967

The figures relating to chemical manure indicate a small expansion, but those dealing with the export of alkali and bleaching materials indicate a contraction of trade. There was a small spurt in the years 1890-92, but last year's trade was only fractionally better than that of 1888, as regards alkali.

On the other hand, if we refer to statistics dealing with Germany's exports, we find that she has increased her shipments to this country of the following goods, comparing 1889 with 1891, the latest year for which figures are available:—

	from	Metric Centners.*
Caustic soda	228 to 3258	
Alum	26987 to 33,137	
Soda calcined	3373 to 21,164	
" crude	621 to 19,947	
Ammonia and coal-tar	13,867 to 18,194	
Sulphuric	1,379 to 19,087	

\* Metric Centner: About 35 lbs. avoirdupois.

It is significant that our exports to Germany have decreased in the case of bleaching powder from 34,555 metric centners to 28,451 centners; from 278,396 to 198,840 metric centners in the case of sulphate of ammonia; from 34,001 to 12,264 metric centners for catechu; from 27,706 to 19,526 metric centners for cinchona bark; from 22,678 to 14,100 metric centners for carboic acid. The list could be further extended, but it is sufficient to show that in many lines of chemical industry we have been losing ground with Germany, while that country has gained the trade. The comparisons quoted above are 1889 with 1891.

In some lines Germany has an absolute monopoly, as, for instance, in manufacture of kieserite, which is made exclusively in that country. The chemical trade of Germany in many articles is sufficiently strong to disregard the Customs barriers raised by other countries in the shape of protective tariffs. When a foreign country imposes duties on articles of her chemical industry, these do not lose their sphere of trade; the foreign country simply pays the duties because cannot do without German chemicals.

It would be very interesting to inquire how it is that Germany has been able to occupy this strong position. The answer is partly to be found in the superior system of technical training, as applied to this industry, pursued in Germany, and partly to some natural advantages. The fact that her system of training is superior to our own must be admitted when we have to go to a foreign country for a competent person to teach the art of dyeing and calico printing to our own operatives. Up to the present the cost of production, so far as labour is concerned, has been rather favourable to German manufacturers. In England, according to Mr. Charles Booth (*Chem. Tr. Jour.*, 341, p. 351), 5 per cent. of the persons engaged in our chemical industry receive under 20s. per week; 25 per cent. earn from 20s., but under 25s.; 20 per cent. receive from 25s., but less

than 30s.; 25 per cent. earn from 30s., but under 35s.; 15 per cent. from 35s., and less than 45s.; while the remaining 10 per cent. receive 45s. and upwards. In America we know that most of the employes engaged in making chemical preparations (compounded) receive from 36s. to 40s. a week, while those engaged in the manufacture of dyestuffs earn from 32s. to 3*l*. and even more (this Journal, 1894, 557). In Germany it is undoubtedly less, as the cost of living is much cheaper than in England or the United States, although it is known that the tendency of late years has been to increase the cost of living in Germany—more especially in the principal towns.

Although Germany has been extending her foreign trade in this respect, yet it does not follow that her manufacturers have been proportionately successful in obtaining good pecuniary results. Indeed, so far as statistics are available, the reverse appears to be the case. Out of 85 factories, no fewer than 24, or 28·23 per cent. of the whole, have yielded no dividend for some years; four have paid a maximum dividend of 2½ per cent., or 4·71 of all the companies; 7, or 8·25 per cent. of all the companies, have paid a maximum dividend ranging from 2½ to 5 per cent.; 8, or 9·41 per cent., have paid a maximum dividend of from 5 to 7½ per cent.; 22, or 25·88 per cent., have paid a maximum dividend of from 7½ to 10 per cent.; while 13, or 15·29 per cent., have declared dividends of from 10 to 15 per cent., 7, or 8·24 per cent., have paid a dividend of more than 15 per cent.—(*Chemical Trade Journal*).

#### MANGANESE ORE IN VIRGINIA.

Some very fine manganese ore has recently been found on the Glenmore property, about two miles from White Sulphur Springs, Va., and the deposit or series of deposits has been traced on the surface outcrop for nearly two miles. The first carload of the ore taken out was shipped to the Carnegie Steel Company, Pittsburgh, and was settled for on the following analysis: Iron, 0·200 per cent.; manganese, 49·964 per cent. As no deduction was made for phosphorus, it is safe to assume it to have been below the Bessemer limit. Other analyses of samples of this ore give an average of about 0·1 per cent. phosphorus, and from 1 per cent. to 3 per cent. silica; the manganese going up to 55 per cent., and iron sometimes down to a trace. This ore is pure enough for chemical manufactures, and as the amount of it seems to be very great, it promises to be a very important find. Some 200 or 300 tons of the ore are now being shipped to the Carnegie Steel Company, which pays from 28 to 30 cents per unit for the manganese and 0·06 cent. for the iron. Such ore would, however, be worth much more to the chemical manufacturers than to the steelmakers on account of its remarkable freedom from iron and its high contents in manganese. For the information concerning this important find we are indebted to Mr. Wm. N. Page, manager of the Ganley Mountain Coal Company, at Ansted, W. Va.—(*Engineering and Mining Journal*).

#### ARTIFICIAL CITRIC ACID.

For some considerable time there have been rumours of the artificial production of citric acid from a sugar solution, by growing in it a fungus. The new method has been the subject of prolonged experiment in a chemical factory in Alsace well known for the many synthetic products that have been brought into commerce by it. The news of the discovery has created much uneasiness in the West Indies—notably in Dominica—where the preparation of concentrated lime-juice for citric acid manufacture is an industry of some importance. The uneasiness has been allayed somewhat, however, by a letter read by Dr. Alfred Nicholls, of Dominica, from a London drug firm, in which the opinion is expressed that the experiments are not likely, within the near future, to reach a stage at which they would become dangerous to the lime industry. This letter appears in the current issue of the *Kew Bulletin*, in which is also printed a communication, dated 13th June, from the British Ambassador at Berlin on the same subject. Sir E. B. Malet states that, according to information which he has received from the Imperial German Foreign Office, the director of the chemical works at Thann, in Alsace, states that the result

of the experiments in the production of citric acid from sugar solution increases the prospect of ultimate success, but that certain difficulties have been encountered which must be overcome before there can be any question of the mercantile utilisation of the process.—(*Chemist and Druggist*).

#### THE EXPORT OF TINCTURES AND ESSENCES.

##### *Concessions by the Board of Inland Revenue.*

The following general order, No. 15, 1894, dated June 18th, 1894, containing further regulations on the subject of the exportation, on drawback, of tinctures and flavouring essences, has recently been issued by the Board of Inland Revenue:—

The attention of the service is directed to the following changes in the existing regulations affecting the exportation of tinctures and flavouring essences:—

1. Tinctures and flavouring essences may be exported in bottles or metal canisters, holding any quantity, packed in cases each containing not less than two liquid gallons. Essences, however, in bottles not exceeding 4 oz. each, may be packed in 1-gallon cases, but no consignment less than 2 gallons can be exported. The bottles or canisters may be of different sizes, but the number of such sizes that may be packed in a case is not to exceed three. Tinctures and essences may be packed in the same case.

2. Jars, covered with wicker-work, containing not less than two and not more than five gallons, and iron drums holding not less than two and not more than ten gallons, may be exported without being cased, but a wooden tally showing the distinguishing particulars required to be branded, or inscribed on a case, must be affixed securely by wire to the neck of each jar or drum.

3. The exporter must set apart the bottles or canisters intended for each case, grouping each size, so that the officer may conveniently count them and test their contents. When metal canisters are used they must not be finally corked, or otherwise closed, until the officer has fully satisfied himself that the contents correspond with the specification in the notice to pack.

4. The quantity of tincture or of flavouring essence in any bottle or canister, whether to be invoiced by weight or otherwise, is to be ascertained by imperial measure.

The exporter, in his notice to pack, must specify the following particulars against each different size of bottle or canister:—

(a.) The quantity in bulk to the nearest thousandth part of a gallon which each bottle or canister contains. And as to bottles not exceeding four ounces each, the total contents of six such bottles may be declared.

(b.) The total number of bottles of each size.

(c.) The total quantity in bulk gallons and parts of a gallon.

(d.) The alcoholic strength at proof.

(e.) The proof gallons and parts of a gallon.

5. Whenever practicable the officer should check the bulk quantity by the ordinary standard imperial measures provided by the exporter. When the quantity in any bottle or canister does not correspond to the recognised imperial measure, as a gallon, quart (0·250 gallon), pint (0·125 gallon), or half-pint (0·062 gallon), graduated glass measures, which will be supplied to supervisors on application to the principal of the laboratory, are to be used, and the quantity checked to the thousandth part of a gallon. The calculations for drawback are to be regulated by the order of February 4, 1893, whether the bottles or canisters be measured singly or in groups of six.

6. When the number of bottles in any consignment does not exceed 100, the officer is to measure 1 in every 25. When it exceeds that limit, then 1 in every 50 after the first 100. When canisters are used the measurement of not less than 1 in 10, and, if jars or drums, not less than 1 in 5, should be checked. A larger proportion of bottles may be measured should the officer, from any exceptional circumstances, consider it necessary.

7. Spirits of nitre need no longer be sampled in each consignment. This preparation however, should be frequently sampled, but when of the same strength one

sample from any number of consignments, on the same day, and belonging to the same exporter, will be sufficient.

8. The exporter should, as a general rule, enter on separate forms preparations packed in any consignment which carry different rates of allowances for waste, or which are not scheduled as entitled to any such allowance. If more convenient, however, they may, in the case of small consignments, be shown in separate groups on the same form, and in either case the allowance claimed must be stated—*Chemist and Druggist*.

#### COAL IN IRELAND.

During the past 18 months boring operations have been carried on at Dungannon, under the direction of Mr. Donald Munro, to prove the existence of coal. The work was brought to a successful issue this month, when a seam of bituminous coal, 5 ft. 11 in. in thickness was struck. The depth at which the seam was discovered is 188 yards from the surface. Arrangements will be made by the Dungannon Collieries Company, Limited, for working the coal at an early date. The company own 1,800 acres of land in the neighbourhood, and the engineer is of opinion that coal lies under the whole of this area. A stratum of red sandstone intervenes between the surface and the coal measures.—*Chemical Trade Journal*.

#### THE NITRATE OF SODA MARKET.

The market opened in January at 9s. per cwt. as the value of arrived cargoes, and 9s. 1½d. to 9s. 3d. for spring arrival, holders being in a very confident mood.

The actual consumption in Europe for the half-year amounts to 588,000 tons, of which the Continent took 503,000 tons and the United Kingdom 85,000 tons. This represents an increase of 11 per cent. on the Continent and

20 per cent. in the United Kingdom as compared with the same period last year. Such an increase we fully anticipated in our circular of 31st December last.

There is no material change to note in the consumption in the United States, which remains very stationary at the rate of about 100,000 tons per annum.

The consumption in Europe for the first six months of the past three years has been as follows:—

	1892.	1893.	1894.
	Tons.	Tons.	Tons.
Continent .....	493,000	451,000	503,000
United Kingdom .....	84,000	71,000	85,000
	577,000	522,000	588,000

Whilst the consumption for the twelve months ending 30th June 1892, 1893, and 1894 has been:—

	1892.	1893.	1894.
	Tons.	Tons.	Tons.
Continent .....	613,000	633,000	733,000
United Kingdom .....	114,000	102,000	114,000
United States .....	100,000	100,000	100,000
	827,000	835,000	947,000
The shipments for the same period have been.....	907,000	765,000	1,004,000

#### NITRATE OF SODA.

*Shipments, Consumption, Stocks, and Prices, from 1887 to 1894.*

		1888.	1890.	1892.	1894.
Shipments from South American ports to all parts for the six months ending 30th June.	Tons	268,000	335,000	402,000	450,000
Do. for the 12 months ending 30th June.....	"	715,000	909,000	907,000	1,004,000
Afloat for Europe on 30th June.....	"	148,000	138,000	180,000	225,000
Stocks in United Kingdom ports:—

Visible supply on 30th June (including the quantity afloat, for Europe and Stocks in United Kingdom and Continent) .....	"	180,000	254,000	304,000	258,000
Price on 30th June .....	per Cwt.	9s.	8s.	8s. 3d.	9s. 1½d.

## THE BENGAL SHELLAC INDUSTRY.

THE French Consul at Calcutta, in a report upon the present condition of the Indian lac industry, states that the finest descriptions of stick lac are found in Assam and Bengal, that coming from the former country being a very important article of trade. Lac from Burmah, which is chiefly produced in the upper districts and the Shan States, is sent to Calcutta to be worked up. Burmah, it is stated, is in a position to supply endless quantities of lac, as the vast forests there contain many descriptions of trees adapted to its development. The districts of the Punjab and Mysore are large producers of lac, which is chiefly used at the place of production, its inferior quality rendering it unfit for exportation. Then come Bengal, Oudh, Seinde, and the Central Provinces. According to quality, it is either sent to Calcutta to be melted, or to certain towns of the interior, such as Hyderabad and Mirzapore, for working up into bangles and other articles. There are large numbers of lac factories in India, but most of them are of little importance, and only turn out products of very second-rate quality. The methods of manufacture vary according to district. In hat-making, a mixture of lac, mastic pounce, and other resins, dissolved in alcohol, is used to stiffen silk hats, and in lithography lac is used in connection with the preparation of the ink. Mixed with resin and certain colouring material it makes sealing-wax. Lac also enters into the composition of numerous varnishes. In adding to a solution of lac in alcohol a yellow clear substance such as gum gutta, saffron, &c. a liquid is obtained which gives to copper and other metals the appearance of gold, while still preserving their brightness. The quantity of lac exported in 1892-93 amounted to 125,246 cwts. valued at 7,787,583 rupees. In the preceding year the value amounted to 7,444,460 rupees.

— *Ibid.*

## BOARD OF TRADE RETURNS.

## SUMMARY OF IMPORTS.

Articles.	Month ending 30th June.	
	1893.	1894.

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND  
MACHINERY.

## APPLICATIONS.

11,960. G. W. Brown and W. R. Skinner. Improvements in apparatus for evaporating and condensing, and for heating feed-water for steam boilers. June 20.

11,991. W. Evans. See Class XVIII., B.

12,880. G. A. Barnard. Improvements in apparatus for cooling or condensing fluids. Complete Specification. July 3.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

12,941. L. Maiche and C. Maiche. Improvements relating to the purification of water and to apparatus therefor. June 27.

14,840. M. Julien. Apparatus for effecting the intimate mixture of liquids, semi-liquids, or liquefied matters. July 4.

14,900. E. C. Buik. Improvements in apparatus for absorbing gases. July 11.

15,724. J. Harper. An improved apparatus for assisting in the drying of hops. July 18.

16,151. P. J. Worsley, W. Windus, and B. Bracey. See Class VII.

24,266. H. S. Keating. An improvement in hydrometers, saccharometers, and such like instruments. July 11.

1894.

7235. D. McGill. An improved method of and means for the compression of air or other gases. July 11.

## II.—FUEL, GAS, AND LIGHT.

## APPLICATIONS.

11,801. J. Calderwood and J. Hodges. Improvements in treating paraffin scale. June 18.

11,810. J. H. Lamprey. Improvements in apparatus for the rapid and economical production of ozone. June 19.

12,048. W. H. Biggs and R. R. Greenhow. Improvements in the manufacture of artificial fuel from anthracite coal slack and similar substances. June 22.

12,663. E. Hermite, C. F. Cooper, and E. J. Paterson. An improvement in the purification of gas. June 29.

12,761. W. P. Thompson.—From E. Scott, United States. A new or improved combustible material and process of manufacturing the same. July 2.

12,888. J. C. Fell.—From M. M. Armstrong, United States. Method of smokeless combustion of fuel, &c. Complete Specification. July 3.

13,114. E. Daus. Improvements in the manufacture of heating and illuminating gas. July 6.

13,299. J. B. Taylor. Improvements in the manufacture of fuel. July 10.

13,385. B. H. Thwaite. An improved process for generating combustible gas and in apparatus therefor. July 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

12,355. W. Young. Improvements in the production of illuminating gas from mineral oils, and in apparatus therefor, and for producing water-gas. June 27.

12,389. W. B. Hartridge. Improvements in and relating to the manufacture of fuel. June 27.

13,126. W. Young. Improvements in the production of illuminating gas and by-products from liquid hydrocarbons, and in apparatus therefor. July 4.

13,163. H. M. Caldwell and J. E. Tatham. Improvements in and apparatus for distilling or cracking and gasifying hydrocarbon oils and the like. July 11.

14,545. J. Smith. Improvements in the production of illuminating gas. July 18.

15,432. R. H. Laird and W. H. Laird. Improved apparatus for vaporising oil. July 18.

1894.

8588. A. G. Glasgow. Improvements in water-gas apparatus. July 4.

III.—DESTRUCTIVE DISTILLATION, TAR  
PRODUCTS, ETC.

## COMPLETE SPECIFICATION ACCEPTED.

1893.

16,769. F. W. Clark. An improved method or process for the extraction of naphthalene and other hydrocarbons from coal-tar and similar substances. July 11.

## IV.—COLOURING MATTERS AND DYES.

## APPLICATIONS.

11,739. E. von Salis. Improvements in the manufacture of bases applicable for the production of substantive cotton dyes. June 18.

11,769. W. Krauth. A process for the production of 1-phenyl-3-methyl-5-pyrazolones. June 18.

12,145. I. Levinstein and Co., Lim., and I. Levinstein. Improvements in and connected with yellow colouring matters. June 23.

12,214. O. Imray.—From The Society of Chemical Industry in Basle, Switzerland. Manufacture of polyoxothionine colouring matters dyeing on mordants. Complete Specification. June 24.

12,621. A. Ashworth and J. Bürger. Improvements in the production of new colouring matters. June 29.

12,742. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of colouring matters. June 30.

13,156. C. D. Abel.—From A. Fischesser and Co., Germany. Manufacture of naphthylendiamine sulpho acids. July 6.

13,203. C. D. Abel.—From A. Fischesser and Co., Germany. Manufacture of a new 1, 8-amidonaphtholdisulpho acid from 1, 8-naphthylendiaminetrisulpho acid. July 7.

13,260. O. Imray.—From Goerlich and Wichmann, & Co., Germany. An improvement in the manufacture of yellow prussiates from the rhodanalkalis. July 9.

13,443. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Germany. Production of fast dyes on mordanted fibre. July 11.

13,577. J. V. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements relating to the manufacture of nitrosamines. July 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

14,207. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig. Improvements in the production of colouring matters from meta-amidophenol-phthaleines. June 27.

15,269. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of amidonaphtholsulpho acids and colouring matters therefrom. June 27.

15,404. G. Tobias. Preparation of a new  $\beta$ -naphthylaminesulphonic acid by means of the salts of  $\beta$ -naphthylamine and  $\beta$ -naphthylsulfamin acid. June 27.

16,199. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of 2,7-amidonaphtholdisulpho acid and of colouring matters derived therefrom. July 18.

16,780. H. E. Newton.—From The Badische Anilin und Soda Fabrik. The manufacture or production of colouring matters and materials therefor. July 11.

17,141. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of sulpho-acids of the naphthalene series. July 18.

17,141A. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of sulpho-acids derived from  $\beta_1$ -naphthylamine,  $\beta_2\beta_4$ -disulpho acid. July 18.

17,141B. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of  $\alpha_1$ -naphthylamine  $\beta_1\alpha_2\beta_4$ -trisulpho-acid, and of other sulpho-acids derived therefrom. July 18.

17,141C. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of sulpho-acids derived from naphthalene  $\alpha_1\beta_2\alpha_4$  (or  $\alpha_2\beta_2\alpha_4$ ) trisulpho-acid or analogous sulpho-acids. July 18.

17,472. B. Willeox.—From The Badische Anilin und Soda Fabrik. The manufacture and production of new colouring matters and leuco compounds related to the indigo series, and of new materials therefor. July 11.

17,572. B. Willeox.—From The Badische Anilin und Soda Fabrik. Improvements in the manufacture of betamethyleurhodine. July 18.

18,958. A. Bang.—From G. A. Dahl. Processes for the production of dyestuffs. July 18.

1894

9806. J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andicon. Manufacture of new violet, blue, grey, and black substantive colouring matters for dyeing cotton. June 27.

#### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

##### APPLICATIONS

11,754. W. E. Heys.—From G. Malard, France. Improvements in the process of and apparatus for scouring and degreasing wool. Complete Specification. June 18.

13,345. W. P. Thompson.—From P. C. D. Castle, Germany. See Class XIV.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

16,170. W. Littlewood and I. Ingram. Improvements in the method and apparatus for colour-classing and designing for the manufacture of textile goods. June 27.

16,698. E. J. Goodwin. Improved treatment of textile fabrics and production of material suitable for use as tracing cloth. July 11.

#### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

##### APPLICATIONS.

12,303. H. H. Lake.—From La Société Bonnet, Ramel, Savigny, Giraud, and Marnas, France. Improvements relating to the printing of fabrics. June 25.

12,600. H. Baines. A new or improved manufacture or production of a single or multi-coloured list or selvedge on piece-dyed cloths. June 28.

12,722. C. H. Smith. Improvements in bleaching calico, cloth, and other woven fabrics. June 30.

12,762. M. Kalisch, W. A. Rosenberg, and J. Entwistle. Improvements in the manufacture or production of cloths in variegated colours. July 2.

12,866. M. Cockroft. Improvements in apparatus for dyeing stockings, gloves, and other fabrics. July 3.

13,210. H. W. Sanderson. Improvements in and relating to the printing of textile fabrics. Complete Specification. July 7.

13,443. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Germany. See Class IV. July 11.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1893.

13,579. J. Rhodes, jun., and A. B. Perkins. Improvements in apparatus for dyeing slubbing or slivers of fibrous material. July 11.

16,038. T. P. Miller. Improvements in apparatus for treating fibrous materials, yarns, or threads with mordanting, preparing, dyeing, or other liquids. July 11.

1894.

8964. J. W. Abom. Method of bleaching paper pulp or other flocky substances. July 4.

11,077. E. Hoffmann. Improvements relating to dyeing wool with chromium lakes. July 11.

## VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

11,859. G. Bamberg. Improvements in the manufacture of silicate of soda and carbonate of soda, and in apparatus for that purpose. June 19.

11,966. J. Brock, V. C. Driffield, and F. W. Wright. Improvements in and apparatus for effecting the decomposition of gases by means of porous or catalytic material, more especially intended for use in the production of chlorine from hydrochloric acid gas and air. June 20.

11,967. J. Brock, V. C. Driffield, F. W. Wright, and T. Davies. Improvements in apparatus for effecting the decomposition of gases by means of porous or catalytic substance, more especially intended for use in the production of chlorine from hydrochloric acid gas and air. June 20.

11,968. J. Brock, V. C. Driffield, A. Carey, and G. Ogg. Improvements in apparatus relating to the manufacture of chlorine. June 20.

11,988. G. S. Albright and J. J. Hood. Improvements in the preparation of sulphur. June 21.

12,086. H. R. Angel. Improvements in the manufacture of bicarbonate of soda. June 22.

12,218. H. Y. Castner. Improvements in the manufacture of cyanides. June 23.

12,219. H. Y. Castner. Improvements in the manufacture of cyanides. June 23.

12,384. I. A. F. Bang and M. C. A. Ruffin. Manufacture of anhydrous stannic acid. June 26.

12,634. F. Hamer. The production of nitric acid,  $\text{HNO}_3$ , and the nitrates of soda, of potash, and of lime. June 29.

12,675. A. Staub. Improvements relating to the manufacture of sulphuric acid, and to apparatus therefor. June 29.

12,708. G. Dalton and T. B. Provis. See Class XVIII., C.

12,881. H. H. Lake.—From L. Sternberg, United States. Improvements in apparatus for obtaining ammonia and ammonia-salts from nitrogenous organic matters. Complete Specification. July 3.

13,199. C. Raspe. Improvements in the manufacture of soluble metallic phosphate compounds. July 7.

13,202. H. Wilcox. See Class XIII.

13,315. W. McD. Mackey and J. F. Hutcheson. Improvements in the manufacture of ammonia. July 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

12,927. A. Mitscherlich. Process for utilising the lyes of sulphite cellulose products obtained in such process, and apparatus employed for that purpose. June 27.

13,406. R. Haddan.—From Compagnie Electro-chimique de St. Beron. Improvements in or relating to the treatment of sodium chloride, and to the method of utilising the product in the manufacture of white lead, soda, chlorine, and their derivatives. July 18.

16,151. P. J. Worsley, W. Windus, and B. Bracey. Improvements in or connected with pumping and absorbing chlorine gas, and apparatus for use therein. July 4.

17,846. H. W. Crowther and E. C. Rossiter. Improvements in the manufacture of sulphonylides. July 18.

1894.

10,589. O. Imray.—From P. Gredt. Process for treating blast-furnace gases for the extraction of alkaline and ammonium compounds, iodides, and iodine therefrom. July 11.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

## APPLICATIONS.

12,056. R. M. Wight. Improvements in machinery or apparatus for use in the manufacture of sheet glass. June 22.

12,291. W. Hassall and H. W. Sansom. Improvements relating to fire-places for pottery and other like kilns. June 25.

12,789. J. T. Newell. An improved method of decorating glass, earthenware, and metallic substances. July 2.

13,017. P. Shelley. Process of decorating pottery, glass, or similar goods. Complete Specification. July 5.

13,290. H. B. Barlow.—From J. J. Power, United States. Apparatus for blowing and moulding in glass. July 19.

13,293. T. W. Twyford. Improvements in means for uniting or connecting together earthenware and other non-metallic articles, structures, and objects. July 10.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

## APPLICATIONS.

11,973. J. Stow. An improved method of preparing concrete. June 21.

12,233. A. J. B. Ward. Non-slippery pavements. Complete Specification. June 23.

12,350. W. Bruch. A new or improved hydraulic cement. June 26.

12,811. J. Pfeiffer. Improved process for the manufacture of artificial sandstone. July 2.

13,029. S. J. Beaman and J. Deas. Improvements in furnaces for burning sludge, slurry, and like materials. July 5.

13,128. J. H. Lester. Improvements in treating certain waste materials to produce valuable products, such as plaster or stiffening, weighting, and whitening materials therefrom. July 7.

13,607. R. Y. Ardagh. Improvements in the manufacture of wooden blocks for paving and flooring. July 14.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

17,322. A. McLean and C. W. Wilson. Improvements relating to the manufacture of artificial stone. July 18.

1894.

9958. H. Manrer. An improved process of manufacturing porous bricks. July 4.

## X.—METALLURGY, MINING, Etc.

## APPLICATIONS.

11,797. E. D. Kendall. Improvement in the method or process of treating gold and silver ores, and a composition of matter for the same purpose. Complete Specification. June 18.

12,171. W. A. Jenkin. A method for the removal of arsenic, antimony, and bismuth from copper liquors by means of an iron salt. June 23.

12,341. H. T. Barnett. Improvements in and connected with the distillation of zinc. June 26.

- 12,582. O. Klatte. New or improved process for producing rolled bars. Complete Specification. June 28.
- 12,879. E. W. McKenna. Improved process for renewing old steel rails. Complete Specification. July 3.
- 13,038. J. Lakin and C. H. Page. Improvements in the manufacture of wrought iron. July 5.
- 13,048. J. Bedford. Improvements in the manufacture of steel. July 5.
- 13,184. T. Hampton. Improvements in the manufacture of steel. July 7.
- 13,262. A. V. Newton.—From A. Nobel, France. Improvements in welding and soldering metals. July 9.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

- 13,227. C. J. Bagley, L. Roberts, and the Moor Steel and Iron Co., Ltd. Improvements in the means employed for reheating slabs of steel or iron. July 11.
- 15,152. E. C. Broadwell. Improvements in processes of coating metals with aluminium or its diluent alloys. June 27.
- 15,569. L. Maddison. Improvements in the manufacture of iron and steel articles. June 27.
- 15,875. C. Allen and C. Davey. Improvements in apparatus for the manufacture of cast iron and steel. July 4.
- 16,421. H. Schneider. Improvements in the manufacture of armour plates and the like, and apparatus therefor. June 27.
- 16,561. C. Moldenhauer. A process for precipitating precious metals from solutions. July 11.
- 23,619. E. R. Besemfelder. Improvements in the method of separating metals from ores, and from other mixtures or insoluble substances therewith. July 11.
- 24,900. E. Weinberg, R. Carriek, and J. G. Johanson. Improvements in the elimination of the oxides of zinc, iron, and copper from cobalt-oxide, and apparatus therefor. July 18.

1894.

1472. A. H. Bell and C. Carter. An improved apparatus for precipitating gold and silver from cyanide solutions. June 27.
8087. A. A. Ackerman. An improved process for the manufacture of hard-face armour plate. July 18.
- 10,923. W. P. Thompson.—From E. Bertrand and O. Thiel. Improvements in the manufacture of steel. July 11.
- 11,148. W. P. Thompson.—From O. Nicolai. An improved flux for use in soldering aluminium and other metals. July 18.
- 11,574. H. R. Müller and F. O. Müller. A means or apparatus for producing pure castings. July 18.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

## APPLICATIONS.

- 12,045. A. Schanschieff. Improvements in secondary batteries. June 21.
- 12,483. C. P. Shrewsbury, F. L. Marshall, J. Cooper, and J. L. Dobell. Improvements in or connected with electric batteries. June 27.
- 12,650. B. M. Drake and J. M. Gorham. Improvements in storage battery plates. June 29.
- 12,993. A. Cruickshank. Improvements in the electrolytic separation of gold from ores. July 4.

- 13,358. H. H. Lake.—From I. I. Roberts, United States. Improvements relating to electrolysis and to apparatus therefor. Complete Specification. July 10.

- 13,363. W. A. R. Buckland. An improved plate for secondary voltaic batteries. Complete Specification. July 10.

- 13,377. P. Jensen.—From H. C. I. Størmer, Norway. Improvements in processes and apparatus for electrolytically treating salts in solution or in molten state. Complete Specification. July 10.

- 13,499. A. Sinding Larsen. Improvements in process and apparatus for electrolytical decomposition of alkali salts. Complete Specification. Filed July 12. Date applied for, December 12, 1893, being date of application in Norway.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

- 14,056. W. H. Longsdorf. Improvements in electrolytes for primary batteries. July 18.
- 15,355. H. S. Pyne and R. Thompson. An improved electric battery. July 4.
- 15,610. F. G. Bailly and M. Guthrie. Improvements in apparatus for the electrolytical decomposition of brine and other liquids. June 27.
- 16,851. A. Gentzsch. Improved insulating material for electrical purposes and method of producing same. July 11.

1894.

3674. W. H. Longsdorf.—From G. Hewett. Improvements in primary galvanic batteries and in the liquids used therein. July 11.
8061. H. Carnichael. Improved apparatus and process for electro-chemical decompositions. July 18.
9761. T. Craney. Improvements in electrolytic apparatus. June 27.
9949. T. Craney. Improvements in electrolytic apparatus. June 27.
- 10,169. G. R. Blot. Improvements in plates for secondary voltaic batteries. July 4.
- 10,853. J. Y. Johnson.—From La Société L'Accumulateur Fulmen. Improvements in electrical accumulators or storage batteries. July 11.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

## APPLICATIONS.

- 11,832. J. McDonald.—From E. J. Pearson, Australia. Improvements in the manufacture of soap. June 19.
- 11,885. H. Perl. Improvements in and connected with soap pieces. Complete Specification. June 19.
- 12,072. J. P. F. Field. Improvements in and relating to the manufacture of soap for laundry and other purposes. June 22.
- 12,367. J. van Raymbeke and W. F. Jobbins. Process of and apparatus for obtaining glycerine and other products from soapmakers' spent lyes. Complete Specification. June 26.
- 12,782. W. M. Walters. Improvements in the manufacture of soaps. July 2.
- 12,836. C. N. Wilson. Improvements in the method of and apparatus for extracting and refining wool-fat from spent wool-scouring liquor. July 3.
- 13,104. F. Heilbron. Improvements in or applicable to soap in tablets, cakes, or bars. Complete Specification. July 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

16,987. W. Spindler and C. Stautz. Improvements in extracting oil from oil-containing plants and fruits, and in the production of fodder from the residual matter. July 18.

1894.

9179. A. Wendtland. An improved process for removing the green colour from paraffin, vaseline, and lubricating oils, which have had that colour imparted to them by bodies containing oxygen. July 4.

### XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

## APPLICATIONS.

12,299. A. J. Protheroe. A new manufacture of paint. June 25.

12,595. W. B. Priest. Improvements in the manufacture of white lead. June 28.

12,872. F. Evers. Improvements in or relating to rust preventive compositions. July 3.

13,004. J. Clasen. A new or improved binding medium for size colours and method of manufacturing the same. Complete Specification. July 4.

13,145. L. E. Josset. Improvements in and in connection with luminous paint. July 6.

13,198. J. H. Lester. See Class IX.

13,202. H. Wilcox. Improvements in or relating to the manufacture of white lead and nitrate of ammonium. July 7.

## COMPLETE SPECIFICATION ACCEPTED.

1894.

10,424. P. F. Johnson. Improvements in the manufacture of plumbago or graphite, commonly called black lead. July 4.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

## APPLICATIONS.

12,911. P. C. Hewitt. Improvements in glue-making machinery. July 3.

12,914. R. Haddan.—From E. Avellis, Germany. Improvements relating to the colouring of greased leather. July 3.

13,195. T. H. L. Bake and H. A. Leverett. Improvements in tanning skins and hides. Complete Specification. July 7.

13,345. W. P. Thompson.—From P. C. D. Castle, Germany. Improvements in the manufacture of gum or size applicable for use with cotton, wool, silk, linen, or other textile fabrics. July 10.

13,369. P. C. Hewitt. Improvements in clarifying or removing impurities from glue and other substances. July 10.

13,414. A. Herrmann. An improved process for colouring tanned hides by means of smoke. Complete Specification. July 11.

13,596. J. P. O'Donnell.—From J. A. Schweitzer, France. Improvements in the manufacture of artificial whalebone from parchmentised skin. July 14.

### XV.—AGRICULTURE AND MANURES.

## COMPLETE SPECIFICATION ACCEPTED.

1894.

11,297. G. H. Richards. A new or improved apparatus for vaporising compounds or compositions for use in horticulture. July 18.

### XVI.—SUGARS, STARCHES, GUMS, Etc.

## APPLICATIONS.

11,871. J. Wetter.—From J. D. Riedel and Co., Germany. Improvements in and connected with sweetstuffs or sweetening materials. June 19.

12,071. W. H. Percy. Improvements in sugar boiling and in apparatus for use in connection therewith. June 22.

12,408. A. M. Clark.—From La Société Gallet, Gibou, et Cie., France. Process for the purification of caramel produced from sugar, molasses, glucoses, and other saccharine matters generally. June 26.

13,155. O. Imray.—From R. Folsche, Germany. Process and apparatus for the systematic washing of impure sugar. July 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

1894.

8463. B. Lach and H. Benies. Process for purifying and decolourising saccharine juices and solutions. July 4.

9436. F. Hübner. Improvements in the manufacture of white sugar and the like from molasses and in centrifugal apparatus for use therein. June 27.

9441. C. D. Abel.—From L. König.—A process for deadening and bleaching dissolved or fused amylaceous matters. June 27.

### XVII.—BREWING, WINES, SPIRITS, Etc.

## APPLICATIONS.

12,196. A. F. Spencer. Improved preparations to be used in brewing and in the treatment of finished beer. June 23.

12,295. P. C. Vivien. Improvements in or relating to apparatus for distilling, rectifying, and condensing alcoholic and other vapours. June 25.

13,153. E. Hermite, E. J. Paterson, and C. F. Cooper. An improvement in the purification of alcohol, spirits, and the like. July 6.

13,364. C. Rach. Apparatus for the preparation of wort. July 10.

13,492. R. Zdarek. Improvements in the manufacture of alcohol. July 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

14,373. R. E. Evans. Improvements in syrups, extracts, wines, beers, mineral waters, and other liquids. June 27.

16,692. F. H. Collins. Improvements in apparatus for regulating the temperature of fermenting liquids. July 18.

1894.

10,043. J. T. Connell. Improvements in the treatment of hops. June 27.

# XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

### A.—Chemistry of Foods.

12,690. H. Wilson. Improvements in apparatus for the preservation of perishable articles of food and the purification of the air in closed-up places. June 30.

13,003. H. H. Lake.—From F. Delangle, France. Improved food preparations. July 1.

13,031. H. L. C. Paulsen. Improvements in and relating to the preservation of food. Complete Specification. July 5.

13,587. T. H. L. Bake and H. A. Leverett. Improvements in apparatus for preserving animal and vegetable food and other substances. July 13.

### B.—Sanitary Chemistry.

11,991. W. Evans. Improvements in apparatus for cleansing and filtering sewage and impure liquids, and for separating solids or precipitated matters from liquids generally. June 21.

12,893. H. E. Newton.—From The Pinhoe Patent Refuse Destructor Co., Australia. Improvements in apparatus for destroying garbage and house refuse. July 3.

12,903. Count Heinrich von Pückler. Improved means for purifying and disinfecting air and for consuming deleterious gases and vapours. Complete Specification. July 3.

13,171. F. W. Lacey. Improvements in apparatus for the treatment of towns' refuse. July 7.

### C.—Disinfectants.

12,176. J. R. Carruthers. Improvements in preparing and packing arsenic or other materials for use in dipping animals, destroying weeds, and for like purposes. June 23.

12,708. G. Dalton and T. B. Provis. A method of utilising certain by-products of iron and copper sulphides, and other iron and copper ores for the production of persulphate of iron to be used as a disinfectant for the purification of sewage and for other purposes. June 30.

13,067. A. Blackie and E. A. White. Improved preparations for dipping sheep or other animals, for destroying erms or injurious growths and parasites on plants, and for analogous purposes. July 5.

13,092. F. M. Spence. Improvements in disinfecting powders. July 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

### A.—Chemistry of Foods.

1893.

15,169. H. L. Doulton and A. W. Manger. Improvements in and relating to the softening and purifying of water and apparatus therefor. July 11.

15,434. H. B. Briggs. Improvement in the manufacture of condensed-milk preparations. July 11.

15,435. H. B. Briggs. Improvement in the manufacture of condensed-milk preparations, invalids' and children's foods. July 11.

### B.—Sanitary Chemistry.

1893.

10,458. A. P. Hope. Improvements in the treatment of sewage or analogous foul waters or matters for effecting the disinfection and purification thereof. July 4.

13,305. R. C. Tanner. Improvements in the treatment of sewage sludge. July 4.

14,586. A. McDougall. Improvements in covering lead surfaces to protect water and other potable liquids from contamination with lead dissolved in contact therewith. July 18.

15,914. S. Quilliam. New or improved sanitary material. July 4.

16,368. J. Hanson. Improvements in and apparatus for treating town refuse, or excrementitious or like matter, and obtaining useful products therefrom. July 18.

16,522. G. Jarmain. Improvements in the treatment of sewage and waste waters. July 11.

16,948. J. Bunnehr and W. Chataway. Improvements in the ventilation of sewers, and in treating the foul gases generated therein, and apparatus therefor. July 18.

1894.

5792. R. C. Sayer. Improvements in dry closets in which heat is employed to desiccate the soil. July 11.

### C.—Disinfectants.

1893.

15,914. S. Quilliam. *See* Class XVIII., B.

1894.

10,188. A. J. Bault.—From F. Haise. Improvements in insecticides. July 1.

## XIX.—PAPER, PASTEBOARD, Etc.

### APPLICATIONS.

12,978. R. Münch. Improvements in the manufacture of aluminised paper. July 4.

12,981. C. A. P. F. Tschoben. Improvements in rolls or coils of perforated paper. July 4.

13,139. S. Hahn. A process of manufacture of films imitating mother-of-pearl. Complete Specification. July 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

1893.

12,927. A. Mitscherlich. *See* Class VII.

16,947. A. Yockney. Improvements in the manufacture or treatment of paper. July 18.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

### APPLICATIONS.

11,774. O. Imray. — From The Farbwerke vermal's Meister, Lucius, and Brüning, Germany. Manufacture of mandelate of antipyrine. June 18.

11,952. C. D. Abel.—From Haarmann and Reimer, Germany. Process for the manufacture of vanilline from eugenol and isoeugenol respectively. June 20.

12,174. The Peptine Maltine Co., Lim. Peptonised extract of malted and other cereals. June 23.

12,504. A. Hommel. An improved process for the production of purified, sterilised, liquid hæmoglobin. June 27.

12,796. F. W. Fletcher. Improvements in cinchona preparations. Complete Specification. July 2.

12,980. C. D. Abel.—From The Fabriques de Prodnits Chimiques de Thaun et Mulhouse, Germany. Improvements in the manufacture of artificial musk. July 4.

12,987. H. E. Newton. — From the Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of chemical compounds containing iodine. July 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1893.

16,708. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of chemical compounds. July 11.

16,949. O. Inray. — From The Farbwerke vormals Meister, Lucius, and Böhling. Manufacture of caffeine-sulphonates. July 11.

21,853. J. H. Baum. Improvements relating to the production of pyro catechine. July 18.

1894.

5675. C. D. Abel. — From C. Pieper. Improvements in the production of dextrins and leucocenes. June 27.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

11,872. R. J. Crowley. A process of obtaining chemical copies of paintings, pictures, engravings, and prints. June 19.

12,269. A. B. Chatwood. Improvements in photography. June 25.

12,269A. A. B. Chatwood. Improvements in instruments for and methods of measuring the actinic intensity of light for photographic and other purposes. Filed. July 12. Date claimed 25 June 1894.

13,193. H. A. Fardell. A method of producing photographs in colours. July 7.

13,196. J. Joly. Improvements in or relating to photographing in colours. July 7.

COMPLETE SPECIFICATION ACCEPTED.

1893.

18,237. E. Edwards. — From R. Reissner and G. C. F. Hauser. Improvements in the process of making photographic films. July 18.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

12,084. D. Hiekie and G. F. Bentner. Improvements in explosives. June 22.

12,649. D. Hiekie and G. F. Bentner. Improvements in detonators. June 29.

12,716. E. G. Nott. Improvements in or relating to lucifer matches. June 30.

13,256. T. Hawkins, S. H. Hawkins, and H. Hawkins. Improvements in explosives. July 9.

13,276. H. Priester. Improvements in igniting compositions for safety matches. July 9.

13,506. H. H. Lake. — From The Dynamit-Actien-Gesellschaft vormals A. Nobel and Co., Germany. Improvements relating to the manufacture of explosives. July 12.

# THE JOURNAL

OF THE

# Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 8.—VOL. XIII.]

AUGUST 31, 1894.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roseoe, M.P., LL.D., V.P.R.S. ....	1881—1882.
Sir Frederick Abel, Bart., D.C.L., F.R.S. ....	1882—1883.
Walter Weldon, F.R.S. ....	1883—1884.
W. H. Perkin, Ph.D., F.R.S. ....	1884—1885.
E. K. Muspratt ....	1885—1886.
David Howard ....	1886—1887.
Prof. James Dewar, F.R.S. ....	1887—1888.
Ludwig Mond, F.R.S. ....	1888—1889.
Sir Lowthian Bell, Bart., F.R.S. ....	1889—1890.
E. Rider Cook ....	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S. ....	1891—1892.
Sir John Evans, K.C.B., F.R.S. ....	1892—1893.
E. C. C. Stanford ....	1893—1894.

## COUNCIL FOR YEAR ENDING JULY, 1894.

**President:** Prof. T. E. Thorpe, F.R.S.

### Vice-Presidents:

Sir F. A. Abel, Bart., F.R.S.	Sir John Evans, K.C.B., F.R.S.
Horace T. Brown, F.R.S.	E. K. Muspratt.
H. Brunner.	Dr. W. H. Perkin, F.R.S.
John Calderwood.	John Spiller.
Chas. Dreyfus.	E. C. C. Stanford.
Dr. A. Dupré, F.R.S.	Prof. W. A. Tilden, F.R.S.

### Ordinary Members of Council:

R. Forbes Carpenter.	Prof. A. K. Huntington.
Frank Clowes, D.Sc.	Manning Prentice.
Thos. Fairley.	G. N. Stoker.
C. A. Fawcitt.	Wm. Thorp, B.Sc.
Prof. G. G. Henderson, D.Sc.	T. Tyrer.
David Howard.	Frank Wilson.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

**General Secretary:** Charles G. Cresswell.

**Offices:** Palace Chambers, 9, Bridge Street, Westminster, S.W.

### Editor:

Watson Smith, 31, Upper Park Road, Haverstock Hill, N.W.

### Assisted by the following Staff of Abstractors:

H. Auer.....	VII.	W. G. McMillan { X., XI., XII., XXII.	
D. Bendix.....	III.	W. Macnab.....	XXII.
E. Bentz.....	IV., V., VI.	N. H. J. Miller, Ph.D.	XV.
Jos. Bernays, M.I.C.E.	I.	Herbert Morris, { III., IV., XII., XXII.	
Bertram Blount { IX., XI., XII., XIII.		H. S. Pattinson, Ph.D.	VII., X.

R. B. Brown.....	V., VI.	W. Ray.....	V., VI.
J. C. Chorley .. I., XIX., XXI.		J. C. Richardson....	XI.
E. G. Coker, B.Sc....	I.	F. W. Renault....	Patent Lists.
J. H. Collins.....	X.	H. Schlichter, Ph.D. { V., XV., XXI.	
V. Cornish...VIII., IX., XII.		J. Shields, D.Sc., } Gen. Chem.	
C. F. Cross.....	V., XII., XIX.	Ph.D.....	
W. P. Dreyer.....	VI.	E. Sonstadt.....	III., VII., X.
D. E. Jones, B.Sc....	XI.	E. G. P. Thomas	IV., V., XXI.
W. E. Kay.....	VI.	Eustace Thomas.....	XI.
J. J. Knight .. { VI., VII., XII., XV.		L. T. Thorne, } II., III., XVII.	
Chas. A. Kohn, } Gen. Chem.		Ph.D.....	
L. de Koningh	XVIII., XXIII.	H. K. Tompkins, B.Sc.	X.
T. A. Lawson, Ph.D.	IV., XX.	V. H. Veley, M.A.	Gen. Chem.
F. H. Leeds, III., XII., XXI.		Jas. Walker, D.Sc., } Gen. Chem.	
J. Lewkowitsch, } III., XII.		Ph.D.....	
A. R. Ling ..	IV., XVI., XVII.	C. Otto Weber, Ph.D.	IV., XII.
D. A. Louis.....	IX., X., XV.	J. G. Wells.....	XVII., XX.
F. Machenhauer	III., IV., VI.	A. Wingham.....	X.
		C. R. Alder Wright, } VII., X., D.Sc., F.R.S.....	XI., XII.

## THE JOURNAL.

### Publication Committee:

The President.

A. H. Allen.	Prof. A. K. Huntington.
L. Archbutt.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	C. Clarke Hutchinson.
Joseph Bernays, M.I.C.E.	Wm. Kellner, Ph.D.
H. Brunner.	Ludwig Mond, F.R.S.
E. Rider Cook.	B. E. R. Newlands.
W. Y. Dent.	John Pattinson.
Chas. Dreyfus, Ph.D.	W. H. Perkin, Ph.D., F.R.S.
Sir John Evans, K.C.B., F.R.S.	H. R. Procter.
Percy Gilchrist, F.R.S.	Boverton Redwood.
John Heron.	John Spiller.
D. B. Hewitt, M.D.	Wm. Thorp.
David Howard.	Thomas Tyrer.
Prof. J. J. Hummel.	

## NOTICES.

Notice is hereby given that, in accordance with the alterations in Rule 27 sanctioned at the Annual General Meeting in Edinburgh, all new members elected after January 1st next, and also those elected after the date of this notice who do not pay subscription for 1894, will be required to pay an entrance fee of one guinea. In accordance with the same rule the Life Composition Fee will be 20*l.*, instead of 15*l.* as heretofore after the 1st January next.

## BANKERS' ORDERS.

For the convenience of Members, the Treasurer has arranged with the Bankers of the Society that they shall collect subscriptions from Bankers in town and country; and Members, who have not already done so, are invited to fill up and sign the Banker's Order enclosed with the December number of the Journal, which should then be sent to the Honorary Treasurer, Mr. E. Rider Cook, East London Soap Works, Bow, E.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SCOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

Notice is hereby given that the next List of Members will contain the professions or business occupations of the Members of the Society. Any Member who desires to confirm or alter his description as given before election should communicate with the General Secretary.

## CHANGES OF ADDRESS.

Benjamin, Dr. M., 1/o Bond Street; 589, West End Avenue, New York City, U.S.A.

Blackwell, G. G., 1/o Irwell Chambers West; The Albany, Oldhall Street, Liverpool.

Cameron, Jas., 1/o Polmont; c/o the British Explosives Syndicate, Limited, Pitsea, Essex.

Dukes, T. Wm., 1/o Cape Town; c/o P. T. Petersen and Co., P.O. Box 210, Johannesburg, S.A.R.

Dyson, S.; Journals to c/o F. Dyson, 2, Exchange Place, Middlesbro'.

Emmens, S. H., 1/o San Francisco; Amador City, Cal., U.S.A.

Gray, Wm., 1/o Hall; Cliff House, Barton-on-Humber.

Hall, Allan T.; Journals to c/o Sissons Brothers and Co., Limited, Hull.

## Obituaries.

C. R. ALDER WRIGHT, D.Sc. (Lond.), B.Sc. (Vict.), F.R.S.

MEMBER OF COMMITTEE OF THE LONDON SECTION OF THE SOCIETY OF CHEMICAL INDUSTRY.

CHARLES ROMLEY ALDER WRIGHT was born in 1844 at Southend, and was the youngest child of Romley Wright, a civil engineer of Scotch extraction, on the ordnance survey, who was a man of great intellectual power, and singular individuality of views. He himself undertook the education of his son, and even taught himself Greek that he might impart a knowledge of that language to his boy. Thus it came about that the preliminary training of Alder Wright, whilst conducted upon a broad literary basis, was distinctly designed as that of an engineer. But the subject of this memoir was otherwise inclined, for he soon and unmistakably manifested an enthusiasm for experimental chemistry. Little wonder that on passing from home to Owens' College (1861), inheriting as he did the intellectual force and individuality of his father, together with a faculty for hard work,—he should excel with ease in everything he took in hand. Charles Romley Wright, as he was better known in the college days, was not only a well-known and distinguished figure in the chemistry classes and laboratory under Roscoe, but almost equally so on the physical, mathematical, and classical sides of the college. He even distinguished himself in the Greek Testament and Hebrew Bible classes.

In those early days of the older Owens' College, the College Union was started, and though usually taking little part in debates, none of his old fellow-students who heard it will forget a remarkable lecture and its remarkable illustrations and argument, partly read and partly delivered by him, on phrenology and mesmerism. The first piece of original research prosecuted by Wright, took place in the laboratory of Roscoe, on the *Chemical Action of Sunlight* (1866). This research completed, Wright whilst awaiting the advent of a suitable post, occupied himself at home with scientific work and in the construction of a chemical balance. Every part of this instrument he constructed himself, grinding his own knife edges, &c. The balance still remains and works to perfection. It is an example of patience, mechanical ingenuity, and skill. Just as it was completed, the post of chemist at the Weston works of the Runcorn Soap and Alkali Co., Limited, became vacant through the retirement of Mr. J. W. Kynaston, and Wright was elected to fill it (1866). Here he quickly developed as a chemical engineer as well as an investigator, notwithstanding the very considerable load of physical pain he had now frequently to bear, in consequence of a weakness of the hipjoint, which was gradually giving evidence of more serious trouble.

As the result of the energetic work referred to, in this short year in a chemical factory, several papers of considerable technical importance eventually appeared in the *Journal of the Chemical Society* (1867) and the *Chemical News* (1867). The first was on the Practical Loss of Soda in the Alkali Manufacture, the others were a series of articles on "Losses in various branches of the Alkali Manufacture and Allied Matters." Wright now left Runcorn for London, and became assistant in the laboratory of Dr. Bernays at St. Thomas' Hospital. During that brief period his energies were chiefly engaged in a series of letters and communications to the *Chemical News* on methods then in vogue for testing alkalis, and kindred subjects. Later, in conjunction with Matthiessen (1868-9), as assistant in his laboratory at the St. Mary's Hospital Medical School, a series of four papers was contributed to the *Royal*

*Society*, on "The Derivatives of Opian Alkaloids." About this period too (1869-71) he became associated with Sir Lowthian Bell, F.R.S., with whom he served as research chemist in the laboratory of his ironworks, and here Wright carried out the elaborate investigations on the chemistry of iron smelting, which form the basis of the great work eventually published by Sir Lowthian Bell. From 1871 to the time of his death, Wright was occupied as lecturer in Chemistry in St. Mary's Hospital Medical School, and during this period the following important researches were prosecuted and published by him. Nine papers on Derivatives of Morphine and Codeine, to the Royal Society (1871-74); six papers on Isomeric Terpenes, Brit. Assoc. Reps. (1873-77). Six papers on the Action of Organic Acids and their Anhydrides on Natural Alkaloids, to the Chem. Soc. (1874-80). Seven papers on Narecine, Narcotine, Cotarine and Hydro-cotarine, to the Chem. Soc. (1874-77). Four memoirs on Alkaloids of the Aconites, to the Brit. Assoc. (1877-79). Three memoirs on Alkaloids of the Veratrum, to the Brit. Assoc. (1878-79). Citric Acid in Mulberries, to the Chem. Soc. (1878). Sweet Principle of *Sambucus Eboracica*, to the Chem. Soc. (1881). During this same period an important series of papers was contributed on Inorganic Chemistry and Physical and Electro-Chemistry, among which may be recorded the "Specific Heat of Hydrogenium," (jointly with Prof. Roberts Austen, F.R.S.) (1873); "Chemical Changes accompanying Iron Smelting" (1874); Relations between Affinity and Structural Formulae (1874); series of nine memoirs on the Determination of Chemical Affinity in Terms of Electro-Motive Force to the Phil. Mag. and Proc. of Phys. Soc. (1877-85); four Reports to the Chem. Soc. on Researches on some Points in Chemical Dynamics (1878-80). Amongst a mass of work of technological interest, the following items may be cited: "Pyrites as a Source of Copper, Iron and Sulphur," to Soc. of Arts (1874); series of articles in "*Muspratt's Dictionary*" on Coal Tar Distillation and Products, &c. (1874-75); another series on "Soap, Sulphur, and Sulphuric Acid," in Thorpe's Dictionary (1893); four lectures on "Metals and their Industrial Applications," delivered at the Royal Inst. (1878); articles in "*Encyclopædia Britannica*" on Iron, Steel, &c. (1879-81); Cupro-ammonium Solution and its Use in Waterproofing Paper, &c., to Soc. of Arts (1884); three Cantor lectures on "Manufacture of Toilet Soaps" to Soc. of Arts (1885); "Chemistry of Soap;" "Fluid Specific Gravity Determination for Practical Purposes;" "Certain Aluminium Alloys" (see this Journal 1885 and 1892); nine memoirs on "Certain Ternary Alloys," to Royal Soc. (1889-1894). Of his books, "*The Threshold of Science*," a book for boys and general readers, a long life may be predicted; and a very useful one of the work on "*Oils, Fats, and Waxes*." Even now a considerable number of Wright's investigations have been omitted from reference here.

Dr. Wright was an original member of the Physical Society and of the Institute of Chemistry. He had also been a member of the Council of the Chemical Society.

For some time past Dr. C. R. A. Wright, who all his life had known more or less of pain and infirmity, had become subject to the gradual development of *diabetes mellitus*. More serious tendency had been successfully resisted up to the time of his mother's death, about a year ago. This bereavement, however, proved a terrible trial to him, and it is thought that he had shown signs of failing health from that date. No serious consequences were however anticipated until Monday the 23rd of July. On Wednesday morning, the 25th, he became comatose, and passed quietly away early in the afternoon of that day.—W. S.

## DR. HERMANN JULIUS GRÜNEBERG.

PRESIDENT OF THE COLOGNE SECTION OF THE VEREIN DEUTSCHER INGENIEURE. MEMBER OF COUNCIL DES VEREINS ZUR WAHRUNG DER INTERESSEN DER CHEM. INDUSTRIE DEUTSCHLANDS, COMMERZRIETH DER STAAT KÖLN, &c.

IN the death of Dr. Hermann J. Grüneberg, on June 1st, German chemical industry has lost one of its most distinguished representatives, and in future discussions of the Society for the Protection of the Interests of German Chemical Industry, reported so fully in their organ, "*Die Chemische Industrie*," Dr. Grüneberg will now be greatly missed, and yet more the great knowledge and wise counsel invariably associated with his name.

Hermann Julius Grüneberg was born on the 11th of April 1827, at Stettin, and was the son of Aug. Wilhelm Grüneberg, an organ-builder in that city. He soon manifested a love for natural science, and was, after leaving school, placed under the care of Dr. Ritter, a noted pharmacist, of Stettin, and thus we have another prominent example of the way in which the German Apotheke has so often proved to be the nursery of scientific greatness in the Fatherland. Later on, H. J. Grüneberg entered the works of the chemist, G. Garbe, as a volunteer. He then went to Hamburg, and again entered an Apotheke and worked there for  $1\frac{1}{2}$  years, engaged in the making of all kinds of preparations. After doing military service, by entering the Military Apotheke in Stettin, he commenced to make a definite manufacturing study of white lead, and, only at the age of 23 he started, with some friends, a small factory. This venture did not succeed, and having now lost his patrimony, he accepted the invitation of Ross of Gothenberg to go and assist him in his white lead works in Sweden. He returned in 1854 to Stettin, to join his brother-in-law, Herr Klee, in founding another white lead works. Meantime the Crimean war had broken out, and a vigorous demand for saltpetre arose. This led Grüneberg to devise a process for making artificial potassium nitrate by acting upon sodium nitrate with carbonate of potash, and this process was started in the works originally designed for white lead making. The demand for saltpetre still increased, and a second works was started by Klee and Grüneberg at Bredow, near Stettin, and thereafter a third at Altdamm. The Crimean war over, this abnormally vigorous trade in saltpetre fell. But Grüneberg now possessed means, and thus assisted, he determined to complete his studies, and whilst doing so in Berlin, he kept well in touch with those who conducted the white lead and saltpetre factory, and took occasion to consult his professors, Mitscherlich and Rose, on the theory of the processes, and sought all possibilities of improving them.

In a subsequent treatise on white lead, Mitscherlich spoke most highly of the product of Grüneberg's firm. The great demand for saltpetre being over, Grüneberg proposed a new scheme for Klee's factory, viz., the use of the lixiviate of the ashes of beetroots in the production of ferrocyanide of potassium, &c., and in consultation with Heinrich Rose he managed greatly to benefit his brother-in-law's firm, and also himself to prove an excellent student. Later on he sojourned in Paris, and heard the lectures of Boussingault, Payen, Regnault, Dumas, Frémy, and others. In 1858, Grüneberg visited England and Scotland, and saw some of the factories here, returning to Germany later on, rich in knowledge and experience. In journeying through Cologne he now met for the first time his future partner, Julius Vorster. Later on the two determined to start a saltpetre factory in one of the Rhine provinces, and seeing that an old iron foundry was for sale at Kalk, by Cologne, they purchased it, and in 1858 there was founded the chemical works under the firm, afterwards so well and widely known, of "Vorster and Grüneberg." In 1860 Grüneberg actually found time to go to Leipzig and take his Ph.D. degree, and the same year he was married. With

such a life of unremitting work, study, and experience behind him, no wonder he carried his firm forwards, and steadily advanced to prosperity; and being a man of great enterprise and wisdom, it could be no matter of surprise either, that his counsel was sought in and around the city of Cologne, which he had now made his home. But besides the untiring energy thus manifested, and which eventually proved too much for physical endurance, Dr. Grüneberg possessed an eminently kind and benevolent heart, and so it happens that the news of his death has brought sorrow not only to those within the boundaries of the Fatherland, but to many beyond those boundaries. In this country the name of Grüneberg is chiefly and most widely associated with that masterpiece of technical skill, his continuous ammonia still, which, further improved by Simon, of Manchester, is known as the Simon-Grüneberg still; and the writer can testify to the exceeding kindness with which Dr. Grüneberg, in 1886, received him in Cologne, and showed and explained to him the construction and working of this apparatus. Of this truly great and good man and citizen, the *Kölnischer Zeitung*, of July 4th, thus expresses itself:—"Dr. Hermann Grüneberg hat zu den seltenen Männern gehört, die keinen persönlichen Feind haben, weil alle ohne Unterschied der politischen und confessionellen Richtung sich vor einer Persönlichkeit beugen, die ihre glänzenden Gaben, ihr umfassendes Wissen, ihren grossen Reichtum mit einer nie versiegenden, alles erwärmenden Bescheidenheit und Liebenswürdigkeit in den Dienst des Gesamtwohls ihrer Mitbürger stellt. Sein Leben und Wirken wird in Köln nie vergessen werden.—W. S."

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*Artificial Refrigeration from Central Stations.* D. Branson. J. Franklin Inst. **137**, 1894, 81—93.

SINCE artificial refrigeration became a practical success, many have endeavoured to devise a method of supplying the means of effecting it from a central station, and some 20 or more costly attempts have been made in various towns, including London, Paris, New York, Boston, Louisville, and Nashville. They have all, more or less, proved failures. Messrs. Starr, Thornburgh, and Branson took up the matter some five years ago, and, after careful experiments, devised a system which has been put into successful operation at Denver and St. Louis, in the United States.

The Denver plant has now been working for four years uninterruptedly, although the plant has been twice enlarged and the distributing mains extended. The St. Louis plant has been in successful operation for three years. Until the introduction of a central-station system, only those who had to effect refrigeration on a large scale could afford to install the necessary plant, and thus dispense with the use of ice as a cooling agent. The delivery of the ice, even to large consumers, is one of the main items of cost, whilst to small consumers it is by far the largest item.

The system of refrigeration adopted by the author and his colleagues is that known as the "direct-expansion system," in which liquid anhydrous ammonia under pressure is admitted into a coil, known as the "expansion-coil," where it expands and becomes gaseous. The gaseous anhydrous ammonia is then absorbed by weak *Liquor ammonia*, until the latter is saturated. The latter is then passed on to a separator or still, and anhydrous ammonia driven off and re-liquefied for use again in the expansion-coil, the weak *Liquor ammonia* left, being again used for absorption. In the present central-station system, the liquefying, absorbing, and separating are done at the station, and the "expansion" in the refrigerating chamber of the customer, so that there is no loss of cooling power in transmission. The liquid anhydrous ammonia is sent out from the central station usually at a pressure of 150 lb. per square inch, at summer temperatures, along a service main called the "liquid line." Branches from this lead to the expansion-coils in the customer's refrigerating chambers, through special valves. The temperature in the chamber is automatically controlled by an ordinary thermostat, which operates an electric regulator, the current being supplied by a dynamo and storage battery at the central station. A variation of  $1\frac{1}{2}$  up or down, is usually allowed, although in some cases it is only  $\frac{1}{2}$ . The anhydrous ammonia vapour from the expansion-coil is led back to the central station through a second pipe-line, known as the "vapour line," to be there absorbed. A third line of pipes is provided, termed the "safety line," which is one of the features of the system. It is connected through cocks, which are ordinarily kept shut, with the liquid and vapour lines, near their connections with each expansion-coil, and also in the man-holes at street crossings. In event of any repairs, alterations, or additions having to be made, the cocks on the liquid and vapour lines are closed, and those on the safety line opened. A vacuum is maintained, by means of a pump at the central station, in this line, so that the ammonia vapour in the expansion-coil flows back to the station, and loss is avoided; and the coil can be opened without any ammonia vapour escaping. In a similar manner, any section of the mains can be cut into for repairs, connections, &c., by aid of the cock in the street man-holes. Lately the safety line has been made sufficiently large to serve as a temporary substitute for either the liquid or vapour lines during any alterations, thus avoiding the necessity for even a single hour's stoppage. By careful experiments on the making of joints, all leakage of ammonia has been overcome.

The demand for the cooling medium varies largely under the daily and yearly differences of temperature with all refrigerating plants, and with a central-station plant it is tenfold. The plant must be capable of meeting the largest demand, and must consequently be lightly loaded when the

demand falls, unless some means of equalising the load be adopted. In the present case, the latter is effected by using three reservoirs at the central station: one for liquid anhydrous ammonia, another for strong *Liquor ammonia*, and a third for weak *Liquor ammonia*. The anhydrous vapour returned by the vapour line passes into the absorber, which is fed by weak *Liquor ammonia*. When this is saturated, it is automatically discharged into the reservoir for the strong *Liquor ammonia*, from which it is pumped, as required, into the separator.

These reservoirs, by taking up and giving out automatically the variations from the mean demand, enable the size of the machines to be reduced, and their being worked continuously. It also allows the machines to be shut off altogether for short periods, for repairs &c., without interrupting the supply, and night work to be dispensed with in winter, leaving the absorber and reservoirs to work automatically. With the exception of the reservoirs, the plant does not differ very much from others. The quantity of "cool" supplied to each customer is determined either by measuring the liquid ammonia by a meter, or by calculation, the internal and external temperatures at the refrigerator and its internal surface being known. The cost of laying the triple distributing pipes varied from 9,000 dols. to 22,000 dols. per mile, according to the construction of the road under which they were laid. In an average town, it is estimated to be about 15,000 dols. per mile, including 100 branches for connections. A central station, with duplicate machines, and capable of supplying two or three miles of distributing mains could be built for 50,000 dols. A large station with five or six machines, each of 100 tons capacity, suitable for five or six miles of street, would cost about 200,000 dols. Should it be required to cover a large district, it is better to erect a second station at a distance not exceeding two miles from the first. The limiting distance of distribution is about the same as with illuminating gas.—R. B. P.

*Utilisation of Waste Carbonic Acid Gas in Brewing.*

A. Marcet. Trans. Inst. Brewing, **7**, 199—223.

See under XVII., page 825.

*The Prevention of Bumping in Boiling or Distilling Liquids.* V. Genhardt. Ber. **27**, 964.

See under XXIII., page 838.

### PATENTS.

*Improvements in the Construction of Tanks or Receptacles for the Precipitation of Sewage, and for like Purposes.* E. C. Ives, Derby. Eng. Pat. 13,411, July 11, 1893.

See under XVIII.—B., page 832.

*Apparatus for Effecting the Intimate Mixture of Liquids, Semi-Liquids, or Liquefied Matters.* M. Julien, London. Eng. Pat. 14,840, August 2, 1893.

The apparatus is principally intended for mixing the constituent elements of artificial butter, so as to form a homogeneous product resembling genuine butter, and may also be used for mixing or emulsifying difficultly miscible liquids, or semi-liquids. The different constituents are supplied in regulated proportions to the cylinder II, by means of pumps worked by variable throw eccentrics. The cylinder II is traversed by a piston-rod I, of varying diameter, provided with a strong regulating spring K above, and with its lower end perforated at *n* and furnished with side inlets *m*. The roughly-mixed constituents enter the cylinder II by the inlet *h*, forcing the necked piston-rod I upwards, and thus bringing the orifices *m* above the cup-leather packing; the semi-liquid mass is discharged into these inlets under great pressure, and a thorough mixing or emulsifying takes place. The product is led away to be cooled or solidified in any well-known manner. The spring K is regulated by means of adjustable collars, so that if the pressure is insufficient the orifices *m* remain below the cup-leather packing outside the cylinder II. In a modified arrangement, a group of nozzles may be arranged in a

APPARATUS FOR MIXING LIQUIDS AND SEMI-LIQUIDS.

closed casing, so that the jets issuing therefrom may mix and produce the required product.—E. G. C.

#### Improvements in Earthenware and other Pipe-Joints.

R. Ewing, London. Eng. Pat. 14,926, August 4, 1893.

THE improvements made by the inventor are upon the class of joints described in specifications, Eng. Pat. 3191,

August 22, 1877, J. Rohlius; and Eng. Pat. 9028, May 31, 1889, A. Ramsden; which have cupped or recessed collars and annular grooves or double-sided sockets.

In the socket end an annular groove A is formed, with inner wall B shorter than the outer wall C, and the bottom wall projects at an acute angle from the line of the body of the pipe, so that the plastic material used for cementing the joint is locked in a tapering space D, between the two adjacent end spaces. The outer side of the spigot end is scored on the circumference at A, as is also the inner part of the adjacent socket end, thus holding the cement, which is packed into the mouth of the socket, enabling the joint to withstand a great strain.—V. C.

#### Improvements applicable to Bottles or other similar Vessels used for containing Poisonous Substances. A. Reed, Sheffield. Eng. Pat. 15,609, August 17, 1893.

A METALLIC band fastened round the neck of a bottle supports a vertical rod or wire terminating in a ring or loop, so that a bottle containing poisons and provided with this attachment may be distinguished from other bottles. The wire ring attached to its vertical support and standing over the mouth of the bottle, may also serve as a funnel-holder.

—E. G. C.

#### An Improvement in Compound Asbestos and other Fibrous Packings. A. E. H. Field, London Street, Middlesex. Eng. Pat. 15,622, August 17, 1893.

RELATES to packing of the kind in which asbestos or the like is disposed in layers with cement and caoutchouc strips or rods to form a compound packing. The improved packing has thin perforated sheets of lead or white metal introduced between the layers of fabric, so that during the rolling and pressing operations the fabric is forced into the holes, and causes the mass to cohere.—E. G. C.

#### New or Improved Process or Means for Connecting Metal to Earthenware or China. W. B. H. Drayson, London. Eng. Pat. 23,654, December 8, 1893.

See under 1X., page 811.

#### Improvements in Carbonic-Acid Pressure Apparatus for Vessels from which Liquids are Retained. N. Browne, London. From P. Beck, Augsburg, Bavaria, Germany. Eng. Pat. 1926, January 29, 1894.

THE apparatus is intended to supply carbonic acid gas to beer-barrels and the like, in quantity corresponding to the amount of liquor drawn off. The apparatus consists of a cast-iron reservoir containing carbonic acid, and provided with a reducing valve, the upper surface of which is in free communication with the barrel. When liquid is drawn off the pressure inside the barrel is reduced, and permits the reducing valve to lift and open a small outlet for the escape of carbonic acid gas into the barrel by a side passage until equilibrium is established. A safety-valve is provided to prevent the pressure in the barrel becoming excessive.

—E. G. C.

#### An Improved Mouth Blow-Pipe for the use of Gasfitters and others. W. James, Birmingham. Eng. Pat. 2370, February 3, 1894.

A RUBBER or vessel is placed between the two ends of an ordinary mouth blow-pipe, and is filled with sponge, cotton-wool, or other absorbent. This absorbent is saturated with benzoline, naphtha, or any suitable spirit, so that when the blow-pipe is being used part of the spirit passes in the shape of vapour with the breath and forms the necessary gas.

—L. T. T.

#### Improvements in Receptacles or Tanks for the Storage of Compressed Air, Gas, and Volatile Liquids. W. Timmis, Pittsburg, U.S.A. Eng. Pat. 6681, April 3, 1894.

TWO concentric cylinders are connected to one another by lugs, so that a small space is left between their sides and ends; they are further secured by stay-rods. The cylinders

are heated to a high temperature in a furnace, and while in that condition molten metal of a high density, such as lead, is poured into the annular space between the two casings so as to completely fill it. When the casings cool, the walls contract so as to fill up the pores of the metal and every opening or joint through which leakage might take place. This form of storage reservoir will sustain a very high pressure, and in the case of an explosion there will be a mere rupture, analogous to that which takes place with a copper boiler. The reservoir is especially adapted to receive compressed air, but it may be used for other purposes.—E. G. C.

#### Improvements in Apparatus for Testing Gas Cylinders.

The Scotch and Irish Oxygen Company, Limited, Polmadie, and H. Brier, Glasgow. Eng. Pat. 7914, April 21, 1894.

The figure shows the apparatus in sectional elevation, consisting of a cylinder A, provided with a slightly enlarged

head A' bolted thereon. The upper end of the gas cylinder C is encircled by an annular and removable ring F of india-rubber tube, which can be inflated, backed by plates G, and supported internally by an open metallic ring, which latter is kept in place by means of the clamps E, fastened to a loose ring D on the bottom of the cylinder C. Water under pressure is supplied to the ring F by means of the three-way cock J and pipe I, thereby causing the ring to press outwardly and inwardly to form a tight joint. The expansion of the cylinder C, due to internal fluid pressure, is measured by the height of the column of water in a water-gauge L, connected to the cylinder by a pipe K. A three-way cock M is provided on the pipe connection K, so that the gauge glass may be discharged, and the water-level be brought in it to the zero on the scale.—E. G. C.

#### Improvements in Heating Apparatus or Blow-Lamps for Soldering and other Purposes.

H. H. Lake, London. From B. A. Hjorth and Co., Stockholm. Eng. Pat. 9819, May 19, 1894.

This patent consists in the addition to the petroleum blow-lamp of an external metal chimney, which is contracted just above the annular vaporising or superheating tube. The object of this is to obtain a more regular and intense heating of this superheater, and so attain a more regular and intense flame.—L. T. T.

APPARATUS FOR TESTING GAS CYLINDERS.

## II.—FUEL, GAS, AND LIGHT.

*Electric Heating.* Zeits. f. Elektrotech. u. Elektrochem. 1894, 8—10.

Usual recently it has been generally assumed that heating by electricity is, on account of its cost, of little practical value. But our present experience (e.g., of electric welding) throws doubt on this assumption, and the question is one which must be settled by experiment and measurement. It is true that electrical energy is more expensive than thermal energy derived directly from combustion. But the energy has to be applied to the body which we wish to heat; and in this transference the advantage lies with the electrical form, for the losses by conduction, convection, and radiation are very much smaller. The question therefore takes the form: Which in the end is more economical, electrical energy, which is dear, but convenient and adaptable; or thermal energy, which is cheap, but wasteful in its application? Few data are available for preparing an answer to this question. J. L. Roberts has recently made a useful contribution (Elect. Engineer, Jan. 17, 1894) to our knowledge of the subject; but the writer does not regard his results as decisive, more especially because he has not fully taken into account the economies which are nowadays realised in furnaces. The writer quotes from Rohrbach the following data respecting the metals which chiefly interest electricians, viz., iron, copper, and platinum:—

According to Wagner, 165.75 kilos. of coke are required for the production of 100 kilos. of iron. According to Hering, 1,060 kilos. of coke are required for the production of 100 kilos. of 96—98 per cent. refined copper (English process). In the old Mühlbach furnaces, when ores containing 13 per cent. of copper are smelted, 691 kilos. of coke are employed in producing 100 kilos. of copper. With these results he compares the expenditure (from the smelting to the final preparation of the electrolytic copper) in the Bessemer-copper process. This amounts to only 300 kilos. of coke for 100 kilos. of pure copper. In order to melt 1 kilo. of platinum 300 litres of coal-gas and 100 litres of oxygen are required. As regards the relative cost of furnaces and other plant, the writer is of opinion that the cost of the electrical plant would be as great as, or slightly greater than, that of the usual combustion plant; but the working expenses would be smaller and

the hygienic advantages would be very great. Finally, it should be borne in mind that in smelting operations carbon plays a double part, namely, in the reduction of the ore and in the production of the temperature requisite for this. In the former function it is undoubtedly more economical than the electric current. In the latter function it probably is not; and it is in this direction that fruitful applications of the electric current must be sought.

—D. E. J.

*On the Efficiency of Heating by Electricity as compared with Heating by Combustion.* A. Wilke. Zeits. f. Elektrotech. u. Elektrochem. 1894, 2—3.

THE writer describes and discusses certain experiments made by J. L. Roberts (Electrical Engineer, 1894, Jan. 17), with the object of measuring the relative efficiency of these two methods of heating. Roberts heated masses of metal (rods of platinum and iron) to a red heat, first by combustion methods and then by the electric current. He also heated brass turnings by both methods up to the melting-point. When the substance was heated by a flame, the energy expended was calculated from the loss of weight of the combustible and the (known) corresponding calorific power; when electrical energy was used, the energy expended was calculated from the current and electro-motive force. The amount of heat transferred to the metallic mass was determined by a simple calorimetric experiment (by the well-known method of mixtures). In the first series of experiments a platinum rod, 5 cm. long and 2 mm. thick, was heated in the flame of a spirit-lamp burning absolute alcohol. The wick of the lamp could be covered with a glass cap; and it was weighed before and after the heating. This was effected by holding the platinum rod by means of tongs in the hottest part of the flame; as soon as it became red-hot it was dropped into the calorimeter (a glass beaker). The complementary experiment was made by holding the rod or wire in copper clamps and passing a current through it until it again became red-hot. The results showed that less than 0.5 per cent. of thermal energy produced in the flame was transferred to the bar; whereas 90 per cent. of the energy was utilised in the electrical method.

In the second series of experiments an iron bar weighing about a kilo. was heated, first by means of well-dried charcoal, and then electrically by a Thompson-Schweiss apparatus. In the former case about  $\frac{3}{4}$  per cent. of the thermal energy produced was transferred to the bar; in the latter case about 88 per cent.

In the third series of experiments brass turnings were heated, first by means of charcoal and then in a specially-constructed electric furnace. The efficiency was  $1\frac{1}{2}$  per cent. in the former case and about 85 per cent. in the latter case.

When coal is burned under the boiler of an electric installation, about 10 per cent. of the thermal energy reappears as mechanical energy, and about 9 per cent. as electrical energy. We thus see that in the end about 8 per cent. of the original thermal energy of the coal can be utilised in electrical methods of heating; whereas only 1 to 2 per cent. can be utilised in direct combustion methods. It is evident that the experiments above described were of a somewhat crude nature; but they show sufficiently well that, even in respect of efficiency and economy, electrical methods of heating are deserving of careful consideration.—D. E. J.

*Natural Gas: its Composition and Origin. The Origin of Petroleum. "Researches upon the Phenomena of Oxidation and Chemical Properties of Gases."* Parts 4, 5, and 6. F. C. Phillips. Amer. Chem. Jour. 16, 106—129.

1. *The Composition of Natural Gas.*—The material the author has principally worked upon has been natural gas, as supplied in Allegheny by the Allegheny Heating Company. It is the product of many wells scattered over a considerable area, and represents the

average composition of an enormous volume of gas. From 1886 to 1892 no important differences in its composition have been observed, although occasionally the odour of the higher paraffins has been more strongly marked than usual. Gas from various localities in Pennsylvania, New York, Indiana, Ohio, and British Columbia has also been examined.

In the accompanying table (1.) of analyses will be found the author's results, collated with nine results of the work of others, and these may be compared with the analyses of Russian natural gases shown in Table II. The absence of hydrogen, carbon monoxide ("nearly always stated to occur in natural gas"), the olefines, and sulphur compounds is maintained, but only after a most elaborate search for them, by the author. It is, however, to be noted that gas from Western Ohio and from Canada, which is said to contain sulphur compounds in considerable quantity (see also this Journal, 1891, 507), was not examined by the author. Except in the case of a "gas-well" near Canonsburg—where, after passing the gas through water for several hours, a feeble Nessler reaction was obtained,—ammonia was never found in the gases. Upon the authority of S. A. Ford, of the Edgar Thompson Steel Works, a case is reported where masses of solid ammonium carbonate were blown out of a well by the pressure of the gas.

The paraffins are chiefly methane, with traces of the higher hydrocarbons of the series.

Nitrogen and carbon dioxide are, on the other hand, probably always present.

2. *The origin of Natural Gas and of Petroleum.*—The author inclines to the original hypothesis put forward by the geologists to account for the formation of these substances in nature; or rather, from a study of the phenomena of the slow decay of vegetable matter under water in the absence of air, he puts forward a modification of this hypothesis, considering that, after the first somewhat sudden and tumultuous evolution of gas, vegetable tissue under the above circumstances, relapses into an extremely slow and long continued process of decay. This process may, as he shows, be artificially imitated, and, as he maintains, is the only one known which yields a gas at all similar in composition to that found in nature. Thus, the gas at first given off consists of  $\text{CO}_2$ , 18.23;  $\text{CH}_4$ , 0.30;  $\text{H}_2$ , 62.24;  $\text{N}_2$ , 19.23; while that given off in the succeeding very slow process was  $\text{CH}_4$  only.

The hypothesis of Mendelëeff is objected to, mainly on the grounds that practically no free hydrogen is found in natural gas, though this would be the case, were it the product of the reaction of superheated steam upon metallic carbides. Moreover, natural gas contains neither olefines nor carbon monoxide, yet paraffins alone cannot be produced by any known method of reacting upon iron carbide with steam. The author found the gas evolved by the action of dilute sulphuric acid upon ferromanganese to contain 6 per cent. of olefines.

With regard to Engler's hypothesis, it is pointed out: firstly, that chemically, the gases obtained by Engler, by distillation of menhaden oil and of oleic acid, are very different from natural gas, containing, as they do, from 25 to 38 per cent. of carbon monoxide, and from 12.5 to 2.3 per cent. of olefines, while the paraffins are correspondingly low; secondly, that it is very difficult to point to any known chemical method or any natural process (such as solution in water) by means of which some of the constituents of of such a gas might have been abstracted, so that the residual gas might have come to resemble natural gas, as shown; thirdly, it is pointed out that animal tissues are not capable of a two-stage decomposition, such as is indicated above for vegetable tissues, but when decay once sets in it is rapidly carried on, and without intermission, to their complete destruction.—E. R. B.

Nos. 1, 2, 3, 4, 5, and 6: natural gas from the Caspian region. Communicated to the author by M. Behnmin of Messrs. Nobel Bros., St. Petersburg.

No. 4 is the result of a partial analysis. Nos. 7 and 8: gas from deep borings at Middlesbrough (Bedson: this Journal 17, 922).

*Liquid Fuel.* E. N. Henwood. J. Soc. Arts, 42, 703—704.

The author now contributes further remarks upon this subject, supplementary to those he made during the discussion upon Mr. Stockfleth's recent paper (see this Journal, 1894, 625).

1. He does not agree with Stockfleth's opinion, that the most primitively constructed pulverisators answer as well as the more complicated kinds: on the contrary, the atomiser he employs upon his yacht "Ruby," which is one delivering the oil-fuel as vapour, is practically noiseless, and effects considerable economy. He further states that the great "roar of the blast" is "extremely detrimental" both on vessels on the Caspian and on the locomotives on the Great Eastern Railway.

2. According to Stockfleth the results of atomising the oil by the use of compressed air, "do not materially differ from those obtained with steam": in the author's experience complete combustion is not obtained with compressed air, much soot being deposited in the boiler-tubes.

3. With regard to fire-box arrangements, the author prefers to remove the fire-bars, to entirely close the front of the furnace, and to lead the air-supply through a pipe passing down the funnel: by this procedure heated air supports the combustion, the entire surface of the fire-box may be utilised for heat absorption, and the further advantages are obtained, that the stokehole is perfectly clean, and should any water, shipped during a heavy sea, find its way here, it cannot reach the heated surfaces of the closed-in combustion chamber.

4. The author considers the Petersen's "compound tube water-tube boiler" especially suited to the requirements of liquid fuel, on account of the largely augmented heating surface of the tubes, and other advantages by which—in the author's opinion—"it surpasses all others of every kind."

5. The committee of Lloyd's, the author states, having approved of the oil-fuel system, there can no longer be any question raised as to its safety. Last year's unsatisfactory results on the Clyde are stated to have been caused by "crude arrangements."—E. R. B.

*Estimation of the Secondary Products containing Nitrogen formed during Combustion in the Air.* L. L. de N. Rosva. Bull. Soc. Chim. 11, 1894, 272—280.

It is well known that nitrous and nitric acids are among the secondary products of combustion, and, if the body burnt contains hydrogen, ammonia also. The author endeavours to show the relation between the quantity of these products formed and of the substance burnt. The substances experimented upon were hydrogen, carbon monoxide, coal-gas, wood-charcoal, and coke. Oil was excluded because much ammonia is evolved during heating previous to combustion.

The determinations included estimation of the nitrogen present in the three forms of nitrous acid, nitric acid, and ammonia. In the case of gases the time of combustion for 8—9 litres was 2—3 hours. The charcoal and coke required 8—10 hours for burning, and in this time a certain amount of atmospheric nitrogen would become oxidised to nitrous and nitric acids. A blank experiment served to determine this amount of nitrogen, which was subtracted from the total found. A source of error was traced, in that part of the ammonia formed during the burning of charcoal and coke is derived directly from the substance, and not from atmospheric nitrogen. In fact, in every way the results with charcoal and coke were less satisfactory than in the case of gases: for with the latter the modifying influence of external heat is excluded.

The results may be tabulated as follows:—

I. By burning 1 cubic metre of the gases. (The products are given in grms.)

	HNO <sub>2</sub>	HNO <sub>3</sub>	NH <sub>3</sub>	Nitrogen		Total Nitrogen.
				Contained in Oxidation Products.	Contained in Ammonia.	
Coal-gas .....	0.0212	0.1184	0.0033	0.0401	0.0027	0.0428
Hydrogen .....	0.0215	0.1022	0.0026	0.0299	0.0021	0.0320
Carbon monoxide.....	0.0500	0.0169	.. ..	0.0184	.. ..	0.0184

II. By burning 1 kilo. of the same gases.

	HNO <sub>2</sub>	HNO <sub>3</sub>	NH <sub>3</sub>	Nitrogen		Total Nitrogen.
				Contained in Oxidation Products.	Contained in Ammonia.	
Coal-gas .....	0.0408	0.2554	0.0063	0.0771	0.0052	0.0823
Hydrogen .....	0.2403	1.1411	0.0257	0.3288	0.0236	0.3522
Carbon monoxide.....	0.0339	0.0132	.. ..	0.0147	.. ..	0.0147

III. By burning 1 kilo. of wood or of coke.

	HNO <sub>2</sub>	HNO <sub>3</sub>	NH <sub>3</sub>	Nitrogen		Total Nitrogen.
				Contained in Oxidation Products.	Contained in Ammonia.	
Wood-charcoal dried at 120° C. ....	0.1085	0.3832	0.7874	0.1190	0.6481	0.7671
Wood-charcoal heated to 600° C. for two hours .....	0.1589	0.4186	0.4461	0.1279	0.3679	0.4958
Wood-charcoal heated to 900° C. for two hours.....	.. ..	.. ..	0.0278	.. ..	0.0229	0.0229
Coke heated to 600° C. for two hours .....	0.1122	0.6244	0.1566	0.1756	0.1289	0.3045

IV.—Equivalent values of the products of combustion containing nitrogen. (This table shows the proportion for each combustible between the nitrogen present in the three forms.)

	Equivalent Values.		
	$\text{-- NO}_2$	$\text{NO}$	$\text{NH}_3$
Coal-gas .....	2.4	12.4	1.00
Hydrogen .....	3.4	16.9	1.00
Carbon monoxide .....	4.1	1.0	..
Wood-charcoal heated to $120^\circ \text{C.}$ ..	1.0	2.6	19.61
Wood-charcoal heated to $600^\circ \text{C.}$ ..	1.0	1.95	7.58
Coke heated to $600^\circ \text{C.}$ .....	1.0	4.1	3.77

These figures prove:—

1. That in burning equal volumes of hydrogen and coal-gas, the same weight of nitrogen is transformed into ammonia.

2. That with equal volumes of hydrogen and coal-gas almost equal weights of nitrous acid are formed, but with carbon monoxide  $2\frac{1}{2}$  times as much.

3. In burning equal weights of the gases, by far the largest amount of nitrogen is combined in the case of hydrogen, less than one-fourth of this amount with coal-gas, and scarcely a twentieth with carbon monoxide.

4. That in burning wood-charcoal or coke the ammonia is not produced from atmospheric nitrogen, but as a direct decomposition product of the substance; it would otherwise be difficult to understand why the weight of ammonia should vary according to the heat previously applied. Probably, as a result of the true combustion of charcoal and coke, only oxygen compounds of nitrogen are formed, the weight of these being fairly constant, and the difference shown in the table for coke being due to experimental error.

5. In burning coal-gas and hydrogen the sum of the nitrogen equivalents (see Table IV.) of the acids is 14—15 times as great as that of ammonia; in the case of coke the equivalents of the acids also surpass that of ammonia, the reverse being the case with charcoal.

6. Except with carbon monoxide, more nitrogen is always present as nitric than as nitrous acid.

7. It appears that the maximum of oxidation products is formed in burning gases when the heat of combustion is least, while ammonia is formed in larger quantity as the heat of combustion increases.

The above results give us a new basis for estimating the quantity of nitrogen compounds contained in the air which can serve as plant food. The author concludes that approximately 2,900 metric quintals (1 metric quintal = 100 kilos.) of combined nitrogen pass annually into the air in the form of secondary products of combustion, and become available for the nourishment of plants. This figure is many hundred times less than that given by Boussingault, Lawes, Gilbert, Chabrier, and Bineau.

Doubtless the amount of this nitrogen varies greatly in different regions of the earth. In the author's opinion, the nitrogen present in the air combined with oxygen is in the form of nitric peroxide, with perhaps small amounts of trioxide. It is very probable that nitric peroxide is responsible for many of the effects hitherto attributed to atmospheric ozone. The phenomena of the decolorisation of certain colouring matters by gaseous products of combustion, which is generally attributed entirely to sulphur dioxide, is possibly also partly due to nitric peroxide.

*Electrical Heating by Induced Currents.* Zeits. f. Elektro-  
tech. u. Elektrochem. 1894, 93.

See under XI., page 816.

## PATENTS.

*Improved Apparatus for enabling a Person to Breathe Fresh Air while surrounded with a Poisonous or Noxious Atmosphere, more especially for use in saving Miners from being Suffocated by Choke-Damp or After-Damp.* C. A. Ash, Newport, Salop. Eng. Pat. 13,982, July 19, 1893.

This consists of a hood to fit over the head, made of india-rubber or other soft material, with glazed sight-holes, the lower part being made of india-rubber with an opening at the bottom, which is stretched to admit the head, and then closes round the neck. Reservoirs of india-rubber or light metal, and conveniently formed to carry on the arm, are inflated with air under pressure. These are connected with the hood-piece by india-rubber tubing, the whole being fitted with the necessary valves.

—L. T. T.

*Improvements in or connected with Burners for Hydrocarbon Oils.* R. Lehming, Berlin. Eng. Pat. 15,960, August 23, 1893.

With the view of removing liability of explosion, either by ignition of the body of petroleum vapour in the lamp-reservoir, or, if the lamp is upset, by the passage of oil to the wick, the patentee proposes to surround the wick with a metal tube reaching nearly to the bottom of the reservoir. This tube is detachable, and is attached to the main body of the burner (which is constructed accordingly) by a bayonet or cone connection, so as to be approximately airtight. By this means only the small quantity of vapour above the oil in this tube is in contact with the wick, and should the lamp be upset, the greater portion of the oil is effectually prevented from flowing out through the burner.

—L. T. T.

*Improvements in Round Burners for Mineral Oil.* L. Sepulchre, Herstal, near Liège. Eng. Pat. 16,989, September 9, 1893.

This invention consists in introducing into round disc-burners a second cone outside the one usually present. The second cone is of the same height, or slightly higher, than the usual cone, and is intended to cause a second or additional current of air to impinge on the outside of the flame. It is claimed that additional brilliancy of flame is thus obtained. Various forms of cones are shown.—L. T. T.

*Improvements in and relating to Incandescent Gas Lighting.* M. Bernstein and A. Silbermann, Berlin. Eng. Pat. 7372, April 13, 1894.

The claim of this patent is for a luminous body for incandescent lamps, consisting of a series of superposed inverted cones of varying diameter, made of chamotte or kaolin, or a mixture of the two, and impregnated with a fluid, leaving on heating a residue of magnesia, and called the "illuminating fluid." These cones are arranged on a rod, above a Bunsen burner, so that the edges, which are bevelled and made particularly porous, form an inverted cone just above the tube of the Bunsen. The cones may either be solid or perforated.—L. T. T.

*A New or Improved Composition for so-called Incandescers for Oil, Gas, or other Lamps.* F. H. Medhurst, London. From L. Chander, St. Petersburg. Eng. Pat. 10,427, May 29, 1894.

This composition consists of 55 parts by weight of powdered porcelain, 15 parts of asbestos, 15 parts magnesium oxide, 10 parts of chalk, and 45 parts of silicate of soda or potash. The first four constituents are made into a paste with the silicate, and this paste is moulded into the desired shape, and dried in a drying oven. This composition is said to be highly incandescent, and cheap.—L. T. T.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*The Tar of the Bark of Populus Tremula.* N. Pharmakoffsky. Jour. Ph. Ch. russe, 6, 423—429.

THE tar is a dark-coloured thick liquid of acid reaction. For the neutralisation of 1,000 grms. of it, about 30 grms. of  $K_2CO_3$  are required. Fractional distillation gave the following results:—

		Temperature,			
		100—150°	150—185°	185°—210°	210—260°
Distillate from 100 lb. of tar		3.45	12.3	11	25
		Temperature,			
		260°—330°	Above 330°	Solid Fraction.	
Distillate from 100 lb. of tar		4.6	11.6	15	

The first two fractions form a yellow oil, which turns red on standing. The fraction boiling above 360° C. deposits a green mass slightly soluble in alcohol and ether, very soluble in carbon bisulphide and benzene, and decomposing at 240° C. The rest of the fraction forms a dark-red mass, very soluble in alcohol. The substance is deposited, in the amorphous state, from this solution on cooling; the supernatant alcohol, however, preserving its red colour, which, in reflected light, is green. On treating the mass with ether, a green substance, similar to the one previously mentioned, is obtained. The whole of the tar, and especially the first four fractions, are acid. On treatment of these fractions with potassium carbonate, the salts of valericianic, propionic, formic, and benzoic acids are obtained. The presence of the last-named acid is due to the deposit of populin,  $C_{13}H_7O_7(C_7H_5O)_2$ , contained in the bark. The various fractions were washed with caustic soda, and the solutions obtained, decomposed by the addition of sulphuric acid, in order to separate the acids from the phenols. The re-distillation of the last fraction boiling above 360° C. yields two

fractions, the one being liquid, and containing a few crystals only, showing a bright colour and strong fluorescence; the other forming a compact deposit of fluorescent crystals, with very little adherent oil. Both fractions placed in the dark, in an atmosphere of carbonic acid, turned brown after some time, preserving, however, their fluorescence. The fractions boiling above 270° C. deposit crystals of paraffin, amounting to about 2 per cent. of the tar.—C. O. W.

*The Ethyl Phenols.* A. Behal and E. Choay. Bull. Soc. Chim. 1894, 11, 206.

THIS investigation was undertaken in order to identify the  $C_2$ -compounds occurring in creosote with the ethyl phenols. The ethyl phenols were obtained from ethyl-benzene, prepared according to Friedel and Crafts's method, by converting it successively into nitro-, amido-, and diazo-compounds. By boiling the latter with water, the corresponding phenols were obtained. Ortho-ethyl phenol, a liquid boiling at 203° to 204° C., specific gravity 1.0371 at 0° C. Meta-ethyl phenol, a liquid crystallising at about -4° C., boiling at 214° C., and of a specific gravity 1.0250 at 0° C. Para-ethyl phenol, melting at 46° C., boiling at 215° to 216° C., and of a specific gravity 1.0403.—C. O. W.

*Present State of the Petroleum Industry.* M. P. de Boisieu. Bull. Soc. Chim. 11, 1894, 453.

CRUDE petroleum varies very greatly in its chemical nature, and its technical treatment correspondingly varies; moreover, the increasing number of products obtained from it, and their augmented purity, has of late years necessitated modifications and elaborations of the processes employed; the author has therefore contrasted the state of the art as practised in different countries and with different oils.

1. *America.*—The first fractionation of the crude petroleum is conducted in cylindrical stills of 500—600 barrels capacity, made of  $\frac{1}{4}$ "— $\frac{3}{8}$ " steel plate, and set horizontally in brickwork, like ordinary boilers.

After leaving the stills the vapours are conducted through long iron tubes kept as cool as possible by abundance of water, for it is found that the losses during refining are greatly diminished by adopting this method and by thus working with properly cooled distillate.

At the works of the Standard Oil Company at Bayonne, near New York, six fractions are collected at this first distillation, as shown by the following tabular statement:—

No.	Name of Fraction.	Specific Gravity.	Destination of Fraction and its Products.
1	Light naphthas .....	Up to 0.705 .....	a. Sold as it is, as crude naphtha. b. Sold after re-distillation by steam.
	Heavy naphthas .....	0.705 to 0.744 .....	c. Fractionated into gasoline (sp. gr. 0.696—0.675) and naphtha (sp. gr. 0.675—0.720). d. Fractionated into many products: cymogene, rhigolene, gasoline, light naphtha, naphtha for lighting and heating, and heavy naphtha (substitute for turpentine).
	Extra heavy naphthas (light distillate).	0.744 to 0.765 .....	Fractionated into benzine (added to heaviest fraction of No. 1) and light distillate.
4	"Water white" .....	0.765 to 0.795 .....	Mixed in certain proportions with 5, and refined; the product being "export oil" (flashing point 21° to 24° = 69.8 to 75.2 F.).
5	"Heavy distillate" .....	0.795 to 0.825 .....	After refining is white lighting oil.
6	"Slops" .....	0.825 to the point when oil turns very brown.	.. .. .. ..
7	Residue .....	.. ..	c. Sold, as gas oil, to the gas companies. b. Added to the crude petroleum next to be distilled.
8	{ Tar .....	.. ..	This, while still boiling, is pumped into a vessel where, upon cooling, it separates into:—
9	{ Coke .....	.. ..	Treated subsequently for paraffin and lubricants; and
			.. .. .. ..

The refining of lighting oils is carried out in large reservoirs, constructed of iron plate lined with lead, the funnel-shaped bottoms of which terminate in cocks for

drawing off the waste liquors. To the oil, which is kept in a state of agitation by a current of air, and the temperature of which does not exceed 15°, there is added, little by

little, one half of the sulphuric acid to be used, and the agitation is continued as long as the temperature rises, when the mud-like waste acid ("sludge") is drawn off. The operation is repeated with the second half of the acid, the waste acid being now merely coloured. It can be used a second time. The now straw-coloured oil is thoroughly washed by water, which is forced into the oil from apertures in a tube which passes all round the upper part of the reservoir, and, when acidity has almost disappeared, a solution of soda, of 15 B., is introduced with agitation. The oil is now conducted to the settling tanks, where it may be warmed, to assist the clarifying, by worms suitably placed. Many works, however, prefer to filter through sawdust or coke-dust, as there is risk of colouring the oil yellow by warming it. In some works the oil is washed after the treatment with alkali. Dilute ammonia is sometimes used as alkali. The soda solution employed is about 1 per cent., and the acid about 1.5 per cent. of the volume of the oil to be refined.

The very sulphurous Lima oils are treated by the Standard Oil Company at Whiting, near Chicago, by two recently invented processes. The first of these consists in passing the vapour of crude oil over copper oxide, while with the second the crude oil is distilled in the ordinary way, and the distillates so obtained are redistilled from stills containing copper oxide, the still-contents being kept violently agitated during the distillation. This process is supplanting the other: both require a large excess of copper oxide. The residue, consisting of tar and copper sulphide, is drained, filter-pressed, and calcined, little heat being required for the latter operation, when the oxidation has once set in.

Most of the by-products are utilised; thus, the gases given off at the commencement of distillation are used as

fuel, and so also are the heavy oils, not used for the preparation of lubricants and paraffin. Sulphurous tars are mixed with water and the tar separated from the dilute acid, which is then employed for the manufacture of ferrous sulphate. Sulphuric acid is recovered from sulphur derivatives of petroleum by treatment of these with superheated steam. Other acid and alkaline residues and coke are utilised by ordinary methods.

2. *Russia.* In contrasting the Russian petroleum industry with the American, the following fundamental differences are to be noted:—

(a.) The Russian industry is in the hands of many owners, while the Standard Oil Company produces 85 per cent. of the American petroleum.

(b.) Most of the Russian oil is raised in a small territory around Baku, while there are several American oil-fields, of great extent and considerable distances apart.

(c.) Chemically the oils differ greatly; the Russian containing no paraffin, practically no sulphur, and very little petroleum-spirit, but, with great constancy, 10 per cent. of lighting oil and 40 per cent. of lubricating oil. Further, it is made up of naphthenes and a small quantity of aromatic hydrocarbons, while American petroleum is composed of fatty hydrocarbons, and varies considerably between oils rich in light products, such as those of the Washington and MacDonald Fields; oils rich in heavy products, such as those of Bradford; and sulphurous oils, such as the Lima oils.

(d.) The method adopted in the distillation of the crude petroleum is also different.

Ordinary Baku crude oil has a specific gravity of 0.868—0.885, a flashing point of 35—45°, and a firing point of 15—57°, and is separated, at the first distillation, into the fractions indicated by the following tabular statement:—

No.	Name of Fraction.	Specific Gravity.	Flash-Point.	Products and Uses of the Fractions.
1	Gasolines and spirits,....	0.718—0.760	Under 28	Export forbidden by Russian Government (being a petroleum product containing substances flashing under 28°).
2	Kerosenes,.....	0.760—0.800	28°—55°	Fractions mixed or kept separate according to kerosene required. Usually "Russian kerosene" has specific gravity = 0.822—0.823 and flashing point = 28° ("Kerosene No. 1"). Unlike the American parallel products, never contain substances flashing from 20°—25°.
3	Solar oils,.....	0.866—0.875	Above 100°	Generally mixed with 7, the whole constituting liquid fuel. With a specially designed lamp is excellent illuminant. Also highly suitable for gas-making, on account of high content of aromatic hydrocarbons. (100 kilos. give 2,100 cub. ft. of gas 3½ times stronger than coal-gas—Schibaneff.) This fraction constitutes 15—18 per cent. of the production.
4	Spindle oils,.....	0.892—0.896	153°—163°	Lubricating oil with viscosity = 2.21—2.16 and firing point of 171°—181.
5	Machine oils, No. 1.....	0.906—0.908	170°—175°	Lubricating oil with viscosity 6.5 and firing point 210°—214.
6	Cylinder oils, No. 0.....	0.911—0.912	205°—207°	Lubricating oil with viscosity 9 to 11 and firing point 236°—239.
7	Tar (astatki).....	.. ..	.. ..	1. Liquid fuel. 2. Mixed with 3: the product being used as liquid fuel and in gas manufacture. 3. Caulking of ships. 4. Briquette-making. 5. Constituent of wazgon grease, &c.

The majority of the works only turn out lighting oil; and their residuum, known as "Mazout," is taken in hand by the makers of lubricating oil.

Baku crude petroleum only contains from 33 to 40 per cent. of lighting oil; by very careful manipulation, however, the percentage may be raised to 44 per cent., though the average practice of the Baku works barely exceeds 38 per cent. The yields therefore are:—

1. Spirit, &c.,.....	2
2. Lighting oil.....	38
3. "Mazout".....	100
	100

"Mazout" yields:—

a. Spindle oil.....	12—13
b. Machine oil.....	27—28
c. Cylinder oil.....	1—5
d. Tar and coke.....	17—14

60 60

The most important improvement which has been introduced into the distillation process is the employment, which is becoming very general, of apparatus which can be kept constantly charged. Great advantages are presented by this method over the old intermittent charging, with its occasional spontaneous ignition of the vapours of "Mazout" when the still was emptied, its injuries to the still through the latter being alternately exposed to high and to low temperatures, and its waste of the time necessary for cooling the still, before it was safe to re-charge it with fresh crude oil of initially low boiling point.

Several continuous methods, all based on the same principle, have been proposed; that of Intkisch, one of the most recent, being conducted as follows:—

A number of stills, of like capacity, and each provided with its own heating and steam-injecting apparatus and condensing plant, are arranged in file and connected up, so that the overflow of the first is the supply-pipe of the second,

and so on. The first still is fed from a large tank, placed above it, and containing the stock of crude oil. In this tank is a worm, through which passes the hot overflow oil from the last still: the crude oil entering the first still is therefore warm.

The temperature and the rate of oil-flow are carefully regulated, with the result that each still yields constantly a distillate of a given density. The results are excellent and the apparatus very manageable. Refining is conducted much as in America.

Several attempts have been made to manufacture benzene, anthracene, and other aromatic hydrocarbons, from Baku petroleum, especially in connection with the manufacture of gas from this petroleum, and the author himself conducted experiments, in 1891, at St. Denis (see Bull. Soc. Chim. 1892—3), whereby he was able to show a production of 80 per cent. benzene, at 40 fres. per 100 kilos.; but the heavy fall in price of this substance, from 120 fres. in 1891 to 50—60 fres. per 100 kilos. at the present time, and the anticipation that still further reduction will take place in the price, has deprived this work of the commercial importance it would otherwise have had. (This Journal, 1892, 104.)

3. *France*.—Here crude oil is distilled, by the naked flame, into fractions with the following densities:—

1. Up to 0.725 = 15 per cent. of the charge.
2. 0.725 to 0.740
3. 0.740 to 0.810 } = 70 " "
4. Above 0.810
5. Residue of tar = 15 " "

The tar is submitted to "cracking," in special retorts ("black pots"), by which means about 75 per cent. of useful hydrocarbons are obtained from it, while the loss (gas and coke) is about 25 per cent. After rectification, the bulk of these hydrocarbons are obtained, as an oil of sp. gr. 0.786.

The author acknowledges his indebtedness to the report of MM. Riche and Roume, who in 1892 investigated the state of the American petroleum industry, at the instance of the French Ministry of Commerce and Industry.

—E. R. B.

#### *Petroleum in Sumatra.* J. Soc. Arts, 42, 704.

THE petroleum deposits, discovered in the province of Langkat, at the north of the island, and along the coast of the Malacca Straits, are being rapidly developed. The Netherlands-Indian Government have granted 318 square miles of concessions to Dutch and English capitalists, but only the former are at work.

The wells are put down close to the coast, where there is an excellent harbour. The costs of transit and of shipment are not heavy, the quality of the oil is very good, and it is believed that this portion of the island is very rich in petroleum. Sumatra may therefore, before long, enter into competition with Russia and with America as to petroleum.—E. R. B.

*Asphalt Paving.* Report to the Department of Public Works, Philadelphia, U.S.A. (Pamphlet.) 1894. (This Journal, 1893, 265.)

AN investigation has recently been made by a committee of experts to decide upon the merits of different kinds of asphalt for street paving. The comparative tests carried out for the purpose of the investigation are here abstracted.

The work was divided into three groups—

1. *Chemical Examination*.—On account of the abstention of certain asphalt companies who were invited to offer their raw materials for examination, only two distinct kinds of asphalt and their corresponding paving mixtures were exhaustively dealt with. The following table affords a comparison between the two varieties:—

	Refined Trinidad Asphalt.	Refined Bermudez Asphalt.
Specific gravity at 60° F. ....	1.373	1.471
Bitumen soluble in carbon bisulphide....	61.507 %	97.22 %
Mineral matter (ash).....	34.51 %	1.50 %
Non-bituminous organic matter .....	3.983 %	1.28 %
Portion of total bitumen soluble in alcohol	8.21 %	11.66 %
" " " " ether..	80.01 %	81.63 %
Loss at 212° F.....	0.65 %	1.37 %
" " " " 100° F. in 10 hours.....	7.98 %	17.80 %
" " " " on total bitumen.....	12.811 %	18.308 %
Evolution of sulphuretted hydrogen at...	410° F.   437° F.	
Softening point .....	166° F.	113° F.
Flowing point .....	192° F.	150° F.

The sample of Trinidad asphalt is rather better than the average (cf. Sixth Annual Report of Inspector of Asphalts and Cements, Washington. This Journal, 1893, 267).

2. *Mechanical Tests*.—Mixtures of the asphalts under examination were prepared by heating the asphalt and the appropriate quantity of oil to 300° F., and adding the mineral ingredients, which, like the moulds, rammers, &c., were all kept hot. The mixtures prepared in this manner were filled into cement briquette-moulds and kept for 24 hours at various temperatures. The mixtures were made up with the following proportions:—

	Trinidad.	Bermudez No. 1.	Bermudez No. 2.
Asphalt .....	12.5	9.1	9.1
" Oil residuum " (heavy petroleum oil) .....	2.5	1.0	1.0
Sand .....	58.0	75.0	60.0
Crushed stone .....	23.2	..	..
Powdered limestone .....	3.8	15.0	30.1
	100.0	100.1	100.1

The following is a record of the results of experiments with these mixtures:—

#### *Tensile Tests.*

	Trinidad.	Bermudez No. 1.	Bermudez No. 2.
	Lb. per Sq. In.	Lb. per Sq. In.	Lb. per Sq. In.
At 32° F.....	146.5	399.0	508.5
At 64° F.....	55.5	116.5	204.0
At 108° F.....	19.0	20.0	44.5

#### *Compression Tests.*

	Lb. per Sq. In.	Lb. per Sq. In.	Lb. per Sq. In.
At 32° F.....	1,027.5	1,750.0	1,750.0
At 65° F.....	517.5	..	667.5

The conclusions drawn from all these data may be summarised as follows:—

1. Bermudez asphalt is nearly pure bitumen, containing, moreover, a large proportion of "petrolene" (the portion soluble in a solvent such as petroleum ether). In these respects it is said to be better than Trinidad asphalt.

2. The small proportion of mineral matter in Bermudez asphalt makes it capable of yielding a larger amount of paving mixture than does an equal weight of Trinidad asphalt. The noteworthy amount of organic non-bituminous matter in Trinidad asphalt causes it to decay, especially in street gutters, more readily than Bermudez asphalt.

3. Mixtures made with Bermudez asphalt have a greater mechanical strength than corresponding mixtures containing Trinidad asphalt.—B. B.

*Improved Process for the Extraction of Naphthalene and other Hydrocarbons from Coal-Tar and similar Substances.* F. W. Clark, South Norwood Hill, Surrey. Eng. Pat. 16,769, September 6, 1893.

COAL-TAR, or preferably the distillate obtained in the process of separating pitch from coal-tar, is mixed with naphtha or other light hydrocarbon and passed through an evaporator, which is maintained at a sufficiently high temperature to expel the solvent containing the naphthalene and other hydrocarbons. The naphtha is conveyed by a suitable carrier, such as air, into a condenser, the pitch remaining in the evaporator being drawn off into suitable vessels, whilst the naphtha containing the hydrocarbons is collected in other receptacles. When coal-gas is used as a carrier its illuminating power is increased, and instead of being passed through a condenser it may be conducted through mains to places where it is to be used for lighting purposes. The apparatus employed comprises an evaporator, wherein the liquid to be distilled runs through inclined tubes surrounded by a heating medium and a condenser, and means for circulating a carrier, such as air, through the evaporator and condenser.—D. B.

## IV.—COLOURING MATTERS AND DYES.

*Brasilin and Hæmatoxylin.* J. Herzig. Monatsh. Chem. **15**, 139—146.

By methylation brasilin furnishes a trimethyl derivative, which gives rise to mono-acetyl-trimethyl brasilin, when treated with acetic anhydride and sodium acetate. Tetramethyl brasilin can be similarly produced by heating the trimethyl ether with solid caustic alkali and methyl iodide in sealed tubes at  $130^{\circ}$ — $140^{\circ}$  C., or with alcoholic potash and methyl iodide for 7—8 hours in the water-bath. When purified it melts at  $137^{\circ}$ — $138^{\circ}$ , and cannot be made to yield an acetyl derivative.

In similar fashion, hæmatoxylin furnishes a tetra-methyl derivative, which by acetylation gives rise to mono-acetyl-tetramethylhæmatoxylin, melting at  $178^{\circ}$ — $180^{\circ}$ , and by pushing the methylation process to the utmost, to pentamethylhæmatoxylin, melting at  $144^{\circ}$ — $147^{\circ}$ . In examining

products of this class, Zeisel's methoxyl process furnishes a convenient method of determining pretty sharply the number of methoxyl groups present.

Previous results by methylation go to show that both hæmatoxylin and brasilin behave quite similarly. Other similarities (alkyl derivatives) are observed also, which are only noticed in substances standing in close relationship to xanthone. Beyer has also shown that fluorescein and eosin, with respect to a hydroxyl group, behave exactly like the substances of the xanthone group, and R. Meyer has further pointed out that fluoran, the root substance of fluorescein, is a body of perfectly analogous constitution to xanthone. In future studies of brasilin and hæmatoxylin, the circumstance must, then, be ever kept in view, that in these substances we have compounds similarly constituted in all probability to xanthone or fluoran.—C. R. A. W.

*Synthesis of Gentisin.* St. V. Kostanceki and J. Tarabor. Monatsh. Chem. **15**, 1—8.

GENTISIN,  $C_{15}H_{10}O_4$ , the colouring matter of gentian root, loses methyl on boiling with hydriodic acid, forming *gentisein*,  $C_{14}H_{10}O_4$ , in which three hydroxyl groups are found to be present by acetylation: the parent body, gentisin, only containing two. On methylation, gentisin gives a mono-methyl ether, the same substance being formed by analogously treating gentisein, two methyl groups being introduced during the process; in either case the third hydroxyl group can be substituted by acetylation or benzylation, yielding the same product, whether gentisin or gentisein be the starting point. On fusion with caustic potash gentisein breaks up, forming phloroglucinol and hydroquinone carbonic acid, whence the constitution of gentisein must be that of the trihydroxyxanthone—

The reproduction of gentisein, which dyes upon alumina mordants, from these two decomposition products is somewhat difficult, most of the materials becoming carbonised; by carefully working with small quantities at a time, using acetic anhydride as water-withdrawing agent, the authors have succeeded in synthesising a sufficient quantity for identification. By careful methylation gentisein has been converted into a monomethyl ether, identical in all respects with gentisin; as yet the data extant are not sufficient to decide whether the methyl group thus introduced is situated at position No. 3 or No. 7, but it appears to be at one of the two.—C. R. A. W.

*Some Reactions of Orthotolidine.* H. Schiff and A. Ostro-govich. Annalen. **278**, 375—379.

WHEN benzidine dihydrochloride is boiled in dilute aqueous solution it is partially converted into monohydrochloride, which is sparingly soluble. This reaction does not take place with tolidine dihydrochloride, and the authors only succeeded in obtaining tolidine monohydrochloride by boiling equimolecular proportions of the dihydrochloride and of sodium acetate. In the case of the phenylene and tolylene diamines this reaction produces the hydrochlorides of the mono-acetyl derivatives of the bases. (H. Schiff, Ber. **25**, 2210.) The method which gave the best result was to dissolve 45 grms. of tolidine dihydrochloride in 120 cc. of water, mix this whilst hot with a hot solution of 13 grms. of anhydrous sodium acetate in 60 cc. of water, and boil for two hours, when the reaction becomes almost complete. The monohydrochloride is purified by recrystallisation from water, and forms colourless shining plates, which reddens in the air and are sparingly soluble in cold water. When heated to  $220^{\circ}$  C. the compound becomes coloured, and decomposes without melting above  $300^{\circ}$  C. The dihydrochloride decomposes without melting above  $340^{\circ}$  C. By boiling the monohydrochloride with acetic anhydride it is

converted into dihydrochloride and diacetylolidine, which melts at 304 C., corr. 311 C. Equimolecular proportions of the monohydrochloride and of sodium acetate give tolidine when boiled in aqueous solution. The authors were unable to obtain the hydrochloride of mono-acetylolidine, nor were they able to produce mono-acetylolidine by boiling tolidine with dilute acetic acid. The monohydrochloride treated in the cold with potassium cyanate gave tolidine, and CO<sub>2</sub> was evolved, but no urea derivative was formed. With chlorocarbonic ether the monohydrochloride gives dihydrochloride and tolidine diurethane, melting at 190 C. Compared with benzidine, tolidine behaves as a much weaker base, and with regard to the acetate and the monohydrochloride of the latter the authors assume that these salts are dissociated in aqueous solution. In support of this view as regards the hydrochloride they point out that on boiling its aqueous solution, hydrochloric acid is given off and tolidine crystallises out on cooling. As regards the solubilities of the mono- and dihydrochlorides, the latter dissolves in 17.34 times its weight of water at 12° C., whilst the former at the same temperature requires 112.4 times its weight. Hence the hydrochlorides of benzidine are about five times more soluble at ordinary temperatures than those of tolidine. The method of separating the monohydrochloride is proposed as a means of purifying tolidine, and attention is called to the fact that the solubility of this salt is less in brine than in pure water.

—T. A. L.

*Condensation of Aldehydes with α-Naphthaquinone and α-Naphthaquinol.* J. Wurgaft. J. prakt. Chem. [2], 49, 551—552.

WHEN a mixture of α-naphthaquinol (2 mols.) and benzaldehyde (1 mol.) is dissolved in glacial acetic acid and saturated in the cold with hydrochloric acid gas, the solution soon becomes dark red, and after 4 hours golden lustrous crystals separate. These on analysis are found to have the empirical formula C<sub>22</sub>H<sub>12</sub>ClO<sub>4</sub>·H<sub>2</sub>O. The same compound being obtained by the action of benzotrichloride on α-naphthaquinol in glacial acetic acid solution, it appears that the phenomena are similar to those observed by Doebner (Annalen, 217, 227) on the formation of aurin; the new compound may be regarded as *tetrahydroxydinaphthylphenylcarbin chloride*. By varying the conditions a non-chlorinated product of a similar colour may be obtained; it is the anhydride of a tetrahydroxydinaphthylphenylcarbinol, C<sub>20</sub>H<sub>12</sub>C(OH)<sub>4</sub>·[C<sub>10</sub>H<sub>5</sub>(OH)<sub>2</sub>]<sub>2</sub>. The acetyl derivative (found C = 76.25; H = 4.3 per cent.) melts at 246°, and is converted into the original colouring matter by acids; the acetyl derivative of the leuco base, which latter is very difficult to prepare, gave on analysis C = 79.24; H = 4.4 per cent.

Cuminal and nitrobenzaldehyde yield similar derivatives. α-Naphthaquinone reacts with benzaldehyde, forming a red dyestuff, the constitution of which is at present uncertain. It gave C = 77.0; H = 3.75; Cl = 5.83 per cent.

α-naphthaquinone does not react with benzotrichloride in glacial acetic acid solution.—A. R. L.

*Preparation of Quinoline.* J. Walter. J. prakt. Chem. [2], 49, 549—550.

ACCORDING to Skraup's instructions for preparing quinoline (Monatsh. 2, 141), nitrobenzene (24 grms.), aniline (38 grms.), and glycerol (120 grms.), are mixed with sulphuric acid (100 grms.) in a flask of 2 litres capacity, and the mixture heated therein on a sand-bath, a reflux condenser being attached. The large flask is rendered necessary because of the tendency of the reacting mixture to froth. The author finds, however, that when the nitrobenzene is heated to boiling in a globular flask connected with a reflux condenser and provided with a dropping funnel into which latter the mixture of glycerol, aniline, and sulphuric acid, previously heated on the water-bath, is introduced in portions and dropped therefrom into the boiling nitrobenzene, the frothing is entirely repressed, and

it is possible to work with double the quantities of reagents above mentioned in a flask of 800 cc. capacity. The addition of the mixture of aniline, glycerol and sulphuric acid to the nitrobenzene should extend over a period of  $\frac{3}{4}$  hour. If a large amount of material is being operated upon, it is best to prevent the separation of the liquid into layers by a mechanical mixing arrangement. When all the reagents have been mixed the boiling point is found to be 157°—160°; the whole is then maintained in gentle ebullition for two hours, after which the boiling point sinks to 138°—140° by reason of the formation of water. The unaltered nitrobenzene is then removed by passing a current of air through the liquid. In working on a technical scale enamelled iron boilers are used. The product is now made alkaline and distilled in a current of steam from a capacious cast-iron pot.—A. R. L.

*Aurin.* J. Herzig and Th. v. Smoluehowski. Monatsh. Chem. 15, 73—84.

AURIN and acetyl aurin have been examined by several experimenters with varying results. The authors conclude from their own observations that aurin is C<sub>19</sub>H<sub>14</sub>O<sub>3</sub>; but on acetylation the elements of water are taken up, so that acetylaurin is derived from C<sub>19</sub>H<sub>16</sub>O<sub>3</sub>. On saponification this reproduces C<sub>19</sub>H<sub>14</sub>O<sub>3</sub>. Acetyl aurin contains three acetyl groups, but no hydroxyl group; on reduction it gives rise to triacetyl leucaurin. Aurin, they regard as possessing the structure—

—C. R. A. W.

*Comparison between the Coloured and the Colourless Derivatives of Di- and Triphenylmethane.* A. Rosenstiehl. Bull. Chim. 1894, 11, 213.

1. THE colourless leucaurine is converted into coloured magenta by the substitution of hydrogen by some electro-negative (acid) radical—

2. The compounds—

however, being both colourless, it follows that the amido groups of magenta must contribute essentially to the colouring of this compound. The assumption that this action of the amido group is due to its chemical function, as opposed to that of the electro-negative radicals, is thus borne out.

Further, trinitrotriphenylmethane is colourless; the sodium salt (NO<sub>2</sub>.C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>.C—Na is coloured. Also in this case the opposite chemical functions of the nitro group and of the sodium, coincide with the appearance of colour in the compound.

4. In sulphonated colouring matters the free colour acid, in contradistinction to the previous observation (above), is coloured, and the alkaline salts are colourless. It appears therefore that the introduction of the sulpho group into the molecule suspends the basic character of the amido group present.

5. In magenta, as in all coloured compounds of the same order, the amido groups occupy the para-position towards the methane carbon atom. Only two of the three phenyl

groups require the amido group in para-position. The third may even contain no amido group at all. One amido group is, however, already sufficient to produce the chemical antagonism required for the formation of coloured hydrochlorides, although only those colouring matters are of practical interest which possess at least two phenyl groups substituted in the para position.

5. In order to convert triphenylmethane into colouring matters, at least one of the phenyl groups must be substituted in the para position by either  $\text{NH}_2$ ,  $\text{OH}$ , or  $\text{NO}_2$ , and the methane carbon atom must be in combination with a radical of respectively opposite chemical functions. This may be expressed by the formula—

in which A and B may be phenyl groups substituted in the para position or not,  $r$  and  $r'$  representing radicals of chemically opposite functions. With two para-substituted phenyl groups the formula becomes—

7. In amido derivatives of this class, influences weakening the antagonism between  $\text{NH}_2$  and  $\text{Cl}$  also weaken the dyeing properties of the compounds. For this reason excess of acid or base weakens the colouring power of these dyes, whether sulphonated or not.—C. O. W.

*Naphthalene of Substituted Amidophenols.* F. Ulzer and A. Höller. Mitt. k. k. Tech. Gew. Museums, 4, 1894, 179—181.

One molecule of naphthalic acid and two molecules of dimethyl-*m*-amidophenol were mixed with an equal weight of anhydrous zinc chloride, and heated for from four to five hours in an iron crucible at from 190° to 210° C. The melt was boiled with water to extract the zinc chloride, the residue collected on a filter and washed with boiling water. It possessed a high metallic lustre after being dried. The substance so obtained was treated with dilute ammonia, the solution filtered, and the residue dissolved in hot 50 per cent. alcohol, with addition of some hydrochloric acid. On cooling, some resinous matter separated out, from which the solution was poured off. The latter was then evaporated until the alcohol had almost entirely been expelled, when, on cooling, the solution formed a pulpy mass, on the surface of which, on re-heating, the colouring matter separated out in the form of a semi-solid cake. This was separated from the mother liquor, which, on further concentration, yielded some more colouring matter, but of inferior purity. The dyestuff thus obtained is purified by precipitating its aqueous solution with caustic soda, shaking the precipitate with ether, and precipitating the base from its ethereal solution in the form of the hydrochloride by shaking it with hydrochloric acid. Diethyl-*m*-amidophenol yields a similar dye as dimethyl-*m*-amidophenol, but the yields are very unsatisfactory. The fact of naphthalic acid producing rhodamines is a further proof that dibasic acids, the carboxyl groups of which are in peri-position (1:8), are capable of the same reactions as orthodicarboxylic acids. The formula of the above-described colouring matter is therefore analogous to that of ordinary Rhodamine.

—C. O. W.

*The Action of Light upon Dyed Colours.* Rep. of the Committee (T. L. Thorpe, J. J. Hummel, W. H. Perkin, W. J. Russell, W. de W. Abney, W. Stroud, and R. Meldola). Drawn up by J. J. Hummel. Brit. Assoc. Sect. B. Oxford, 1894.

See under A VI., page 803.

#### PATENTS.

*Improvements in the Production of Colouring Matters from Meta-amidophenolphthalenes.* O. Imray, London. From "The Farbwerke vormals Meister, Lucius, and Brüning," Hoechst-on-the-Maine, Germany. Eng. Pat. 11,207, July 22, 1893.

Red colouring matters soluble in water are produced by condensing alkylated *m*-amidophenolphthalenes with secondary and tertiary bases, such as mono-methyl- and mono-ethyl-aniline, mono-ethyl-*o*-toluidine, methylphenylamine, ethylbenzylamine, dimethyl- or diethyl-aniline, and the shades produced from the tetra-alkylated *m*-amidophenolphthalenes are bluer than those from the dialkylated derivatives. The condensation is effected by means of phosphorus oxychloride, and the following example gives the quantities employed. About 15 to 20 kilos. of ethylbenzylamine are mixed with 10 kilos. of tetra-ethyl-*m*-amidophenolphthalene and 1 kilo. of phosphorus oxychloride are gradually added. The reaction is somewhat violent, and in order to control it, the melt is kept at 60—80° C. for an hour, then dissolved in dilute hydrochloric acid, and the colouring matter is precipitated from the filtered solution with salt. It forms when pure a dark red-brown powder easily soluble in water, alcohol, and glacial acetic acid, and dyes cotton mordanted with tannin in shades fast to soap. In order to obtain the condensation products from primary amines it is only necessary to boil the components together. Obtained in this way the compound from tetra-ethyl-*m*-amidophenolphthalene and aniline melts at 222° C., from *o*-toluidine at 179° C., and from *p*-toluidine at 196° C. These are almost colourless substances, and are precipitated from their solutions in mineral acids by sodium acetate.—T. A. L.

*Improvements in the Production of Green and Bluish-Green Colouring Matters.* O. Imray, London. From "The Farbwerke vormals Meister, Lucius, and Brüning," Hoechst-on-the-Maine, Germany. Eng. Pat. 11,671, July 31, 1893.

This is an extension of Eng. Pat. 12,796 of 1888 (this Journal, 1889, 701), and claims the preparation of colouring matters of the Patent blue series. These are the sulphonic acids of *m*-hydroxydibenzylidiamidotriphenyl carbinol, *m*-hydroxydibenzylidiamido-di-*o*-tolylphenyl carbinol, and *m*-hydroxy-tetrabenzylidiamidotriphenyl carbinol, which are obtained according to the process described in the above-mentioned patent from symmetrical *m*-amidodibenzylidiamidotriphenylmethane, symmetrical *m*-amidodibenzylidiamido-*o*-tolylphenylmethane, and *m*-amidotetrabenzylidiamidotriphenylmethane, or from benzylamine, benzyl-*o*-toluidine, and dibenzylamine, by sulphonating the hydroxy-leuco bases obtained therefrom and oxidising the leuco-sulphonic acids. An alternative method is to condense *m*-hydroxybenzaldehyde with the sulphonic acids of benzylamine, benzyl-*o*-toluidine, or of dibenzylamine, and after sulphonating, to oxidise the leuco-sulphonic acids thus produced to the blue colouring matters (see also this Journal, 1890, 286).—T. A. L.

*The Manufacture or Production of Dye-stuffs.* H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 15,045, August 5, 1893.

These colouring matters, which belong to the class of the oxazines, are obtained by condensing the nitroso-derivatives of secondary and tertiary amines with acetylated or benzoylated (1,2)-amido-naphthols, and subsequently removing the acetyl group or not, as may be desired. A solution of 20.1 kilos. of (1,2)-acetanidonaphthol and 57 kilos. of

nitrosodimethylaniline hydrochloride in 300 kilos. of alcohol or acetic acid is heated to 60–100° C. When the nitroso-compound has disappeared the melt is poured into water and the dyestuff salted out. It dissolves to a blue solution in water, and dyes a reddish-blue on cotton mordanted with tannin. If the acetyl-group be removed by boiling with acids a colouring matter is obtained which dyes mordanted cotton a greenish-blue, and in general the colouring matters produced according to this invention are of a redder shade when they contain an acid radicle than after saponification.

—T. A. L.

*Improvements in the Manufacture or Production of Naphthylamine-sulpho Acids.* H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 15,223, August 9, 1893.

By sulphonating with fuming sulphuric acid the two acids numbered II. and III. (i.e. (1.4.3')- and (1.4.2')-naphthylamine disulphonic acids) of Ger. Pat. 41,957, at a temperature of 50°–100° C., two new  $\alpha$ -naphthylamine trisulphonic acids are produced, the new sulphonic acid group entering the molecule ortho to the amido group. The same acids are produced from the  $\beta$  and  $\delta$  Clève acids: the former, which is (1.5')-naphthylamine sulphonic acid, giving (1.2.4.3')-naphthylamine trisulphonic acid; and the latter, which is (1.2')-naphthylamine sulphonic acid, yielding (1.2.4.2')-naphthylamine trisulphonic acid. The quantities employed are as follows:—One kilo. of Clève's  $\delta$  acid is stirred into 3.5 kilos. of fuming sulphuric acid containing 25 per cent. of anhydride, the melt being kept cool. The temperature is then raised to 50°–60° C. until a sample dissolves easily in water. After cooling, 1 kilo. of 70 per cent. anhydride is added and the melt heated to 80°–90° C. until a test gives no coloration with diazotised sulphanilic acid. The melt is then limed, the calcium salt converted into the neutral sodium salt, and the acid sodium salt is precipitated by adding hydrochloric acid. On treatment with a mixture of nitrous and nitric acids naphthol yellow S is formed.—T. A. L.

*The Manufacture or Production of Amido-naphthol-sulpho Acids and Colouring Matters therefrom.* H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 15,269, August 10, 1893.

The two amido naphthol sulphonic acids described, of which one is new, contain the amido and hydroxyl groups in the (1.1') or peri position. They are obtained by fusing with caustic alkalis the (1.4'.1')- and the (1.3'.1')-naphthylamine disulphonic acids. In the case of both these acid-sulphonic acid group in the peri position to the amido group is replaced by hydroxyl yielding (1.1'.4')-amido-naphthol sulphonic acid and (1.1'.3')-amido-naphthol sulphonic acid. Of these the former has already been described in Eng. Pat. 4613 of 1893 (this Journal, 1894, 244), and no claim is made to it or to the colouring matters therefrom. The starting point for the (1.1'.3')-acid is (1.1'.3')-naphthylamine disulphonic acid, which is prepared by sulphonating acetylated (1.1')-naphthylamine sulphonic acid, removing the acetyl group, and separating the (1.1'.3')-naphthylamine disulphonic acid from the isomeric (1.2.1')-naphthylamine disulphonic acid by the difference in solubility of the sodium salts, that of the latter acid being much less soluble. The constitution of the new (1.1'.3')-acid has been determined by removing the amido group by the hydrazine method and converting the disulphonic acid produced into its sulpho-chloride. The naphthalene disulphonic chloride so produced melts at 138° C., which is the melting point of the (1.3)-sulpho-chloride prepared by Armstrong and Wynne. As already mentioned, when the (1.1'.3')-naphthylamine disulphonic acid is fused with caustic potash it is converted into (1.1'.3')-amido-naphthol sulphonic acid, which can be used for the preparation of dyestuffs by combining it with various diazo and tetrazo compounds in the usual manner.

—T. A. L.

*Production of Para-ethoxy- and of Para-methoxy-phenyl succinimides.* O. Imray, London. From The Farbwerke vormals Meister, Lucius, and Brüning, Höchst a/Main, Germany. Eng. Pat. 15,327, August 11, 1893.

*p-Ethoxy-phenyl-succinimide.*—

prepared by heating together in molecular proportions, succinic acid, and (a) *p*-amido-phenetol hydrochloride, or (b) *p*-acet-amido-phenetol, and subsequently recrystallising the product from hot alcohol. It forms colourless or slightly yellow prismatic needles which fuse at 155° C.

*p-Methoxyphenyl-succinimide.*—This substance resembles the preceding, and is prepared in a similar manner from *p*-amido-anisol, or acet-*p*-amido-anisol. Melting point, 165° C.—H. T. P.

*Improvements in the Production of Iodo-derivatives of the Succinimide and of Substituted Succinimides.* O. Imray, London. From The Farbwerke vormals Meister, Lucius, and Brüning, Höchst a/Main, Germany. Eng. Pat. 15,328, August 11, 1893.

The process in general consists in adding a strong solution of iodine and potassium iodide to the succinimide, dissolved in warm glacial acetic acid. On cooling, the iodo-derivative separates out in the crystalline state. The iodo-derivatives of succinimide, and of *p*-ethoxy- and *p*-methoxy-phenyl-succinimide, are described.—H. T. P.

*Preparation of a New  $\beta$ -naphthylaminesulphonic Acid and of  $\beta$ -naphthylamine, and the Preparation of Salts of  $\beta$ -naphthylsulphamic Acid from the former.* G. Tobias, Berlin. Eng. Pat. 15,404, August 12, 1893.

By the action of sulphuric acid on  $\beta$ -naphthol, the product of the reaction is not, according to the inventor,  $\beta$ -naphthyl sulphate, but (2.1)- $\beta$ -naphthol sulphonic acid. By heating it under pressure with ammonia it is converted into  $\beta$ -naphthylamine sulphonic acid, which on further heating yields  $\beta$ -naphthylamine. When the salts of  $\beta$ -naphthylamine sulphonic acid are heated they are converted into the corresponding salts of  $\beta$ -naphthyl sulphamic acid which are decomposed by mineral acids yielding  $\beta$ -naphthylamine. As to the properties of the (2.1)- $\beta$ -naphthol sulphonic acid, the sodium salt dissolves easily in 80 per cent. alcohol or in water, whilst the potassium salt forms sparingly soluble scales. Both salts are stable when heated in neutral solutions, but the acid is rapidly decomposed when an excess of a mineral acid is present. A neutral solution of the acid gives an indigo-blue coloration with ferric chloride. By the action of diazobenzene sulphonic acid on a strong solution of the sodium salt in presence of sodium carbonate, the sulphonic acid group is eliminated, and there results sulpho-benzene-azo- $\beta$ -naphthol. When the sodium salt is heated with 4–5 times its weight of a 20 per cent. ammonia solution for 10–20 hours to 220°–230° C.,  $\beta$ -naphthylamine sodium sulphonate is produced, together with a little  $\beta$ -naphthylamine. The free acid crystallises in scales or needles, and the sodium salt also separates from water or can be precipitated by means of salt. It forms a yellow crystalline diazo compound which on boiling with dilute sulphuric acid yields  $\beta$ -naphthol sulphonic acid, and on conversion into dichloro-naphthalene it yields the 1.2 isomer, melting at 34° C. When the sodium salt is heated to 230° C. the following conversion takes place:—

This salt is soluble in water, and can be precipitated by adding salt. Mineral acids decompose it, forming  $\beta$ -naphthylamine. It is claimed for the  $\beta$ -naphthylamine made in this way, that it is free from dinaphthylamine and from naphthol.—T. A. L.

*The Production of New Acetnaphthylene-diamine-sulphonic Acids and of Colouring Matters derived therefrom*. S. Pitt, Sutton. From L. Cassella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 15,411, August 14, 1893.

THE acids are obtained by nitrating and reducing the acetyl derivatives of (1.3')- and (1.2')-naphthylamine sulphonic acids, when derivatives of (1.4)-naphthylene diamine are obtained which can be employed for the manufacture of dyestuffs by combining them with diazo or tetrazo compounds. Other dyestuffs are obtained by diazotising the acetyl compound and combining this with a diazotisable amine such as  $\alpha$ -naphthylamine or  $\gamma$ -amido-naphthol sulphonic acid, rediazotising, combining with an amine or phenol, and finally saponifying the product. The acetylation of the naphthylamine sulphonic acid is carried out by heating the sodium salt with glacial acetic acid, and the crude product thus obtained is nitrated in sulphuric acid by adding nitro-sulphuric acid. On diluting with water and adding salt the sodium salts of the nitro acids are precipitated, that from the (1.2')-acid crystallising in needles, whilst the (1.3')-acid crystallises in rhombic plates. Both are easily saponified by mineral acids and the (1.4.2' or 3')-nitro-naphthylamine sulphonic acids obtained dye wool a greenish-yellow from an acid bath. In order to reduce the acids they are gradually added to a boiling mixture of iron-borings, water, and acetic acid. When the solution has become colourless the dissolved iron is precipitated with soda and the new acids are precipitated from the filtrate by adding hydrochloric acid. The acids will combine with diazo compounds, or the acids themselves may be diazotised and combined with phenols and amines. In the latter case, if a diazotisable amine be employed and the azo compound be first saponified, a tetrazo compound is produced when treated with nitrous acid. The following example gives the quantities employed for the formation of one of the dyestuffs referred to in the patent. The diazo compound obtained from 30.2 kilos. of (1.4.3')-amido acetnaphthalide sulphonic acid by means of 7 kilos. of sodium nitrite and 24 kilos. of hydrochloric acid, is added to an alkaline solution of (1.4)-naphthol sodium sulphonate. The dyestuff which separates is filtered off and boiled with 500 litres of 10 per cent. soda-lye until a sample mixed with acetic acid gives a bluish-violet colour. After adding hydrochloric acid and cooling to 0° C., it is rediazotised by the addition of 7 kilos. of sodium nitrite, and the sparingly soluble brown diazo compound is added to an alkaline solution of 38 kilos. of  $\beta$ -naphthol disulphonic acid B. The colouring matter which separates, dyes wool a deep blue from an acid bath.—T. A. L.

*The Manufacture and Production of New Acid Colouring Matters*. B. Willeox, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 16,370, August 30, 1893.

THIS is an extension of Eng. Pat. 3487 of 1893 (this Journal, 1894, 115), referring to the production of acid dyestuffs by condensing the nitroso derivatives of dialkylated  $m$ -amido-phenol with  $\alpha$ -naphthylamine mono- and disulphonic acids. Similar dyestuffs can be obtained from the sulphonic acids of aniline, toluidine, and  $\beta$ -naphthylamine, especially when condensed with diethyl- and dimethyl- $m$ -amido-phenol. The acids most suitable for the purpose are,  $p$ - and  $m$ -sulphanilic acid, aniline disulphonic acid,  $o$ -toluidine- $m$ -sulphonic acid, the so-called  $\alpha$ -,  $\beta$ -,  $\gamma$ - and  $\delta$ - $\beta$ -naphthylamine mono-sulphonic acids,  $\beta$ -naphthylamine disulphonic acid G, and (2.4'.2')- $\beta$ -naphthylamine disulphonic acid. About 69 kilos. of nitroso-diethyl- $m$ -amido-phenol, 50 kilos. of crystallised sodium sulphanilate and 6 kilos. of 30 per cent. acetic acid, are heated on the water-bath for about 12 hours. The melt is then diluted with 1,000 litres of hot water, alkali is added to neutralise the greater part of the acid, and the dye is precipitated with salt. After filtering and washing with brine it is pressed and dried. It dyes wool from an acid bath, giving bluish-violet shades fast to light and alkalis and dyes on very evenly.—T. A. L.

*The Manufacture or Production of Condensation Products from Anines, or Derivatives thereof, by Oxidation in Alkaline Solution*. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 16,708, September 5, 1893.

ACCORDING to Eng. Pat. 19,061 of 1891 (this Journal, 1892, 809), certain yellow dyestuffs can be obtained by treating dehydrothio- $p$ -toluidine sulphonic acid and its homologues with alkaline oxidising agents, resulting in the formation of azo or azoxy compounds. Certain other amines react in the same way, and the present invention describes the preparation of azo and azoxy compounds of  $o$ -,  $m$ -, and  $p$ -nitraniline and of their homologues, of benzidine sulphonic acid and its homologues, and of diamido-stilbene disulphonic acid. Finely-divided  $p$ -nitraniline is mixed with an excess of sodium hypochlorite and dilute caustic soda, and the mixture is allowed to stand until on treatment with nitrite and acid very little colouring matter is formed with naphthol. The product is then filtered off and freed from unaltered  $p$ -nitraniline by washing with dilute hydrochloric acid. The compound is scarcely soluble in water and only slightly in alcohol, but dissolves easily in acetone and chloroform, and crystallises from the latter in reddish-brown crystals with a bluish reflex, melting at 221° C. On reduction with ammonium sulphide it forms a diamido compound which, after diazotisation, combines with amines and phenols, giving substantive azo colouring matters. When completely reduced it yields  $p$ -phenylene diamine. By applying the same process to benzidine  $m$ -mono-sulphonic acid, a product having the constitution—

is obtained. It dyes unmordanted cotton yellowish-orange and can be diazotised on the fibre and combined with amines and phenols. Diamido-stilbene disulphonic acid behaves similarly to alkaline oxidising agents, and the product obtained also gives yellowish orange shades on cotton. The oxidising agents mentioned are hypochlorites or ammonium persulphate, hypobromites, potassium permanganate, or potassium ferriyanide.—T. A. L.

*The Manufacture or Production of Colouring Matters and Materials therefor*. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 16,780, September 6, 1893.

THIS is an extension of Eng. Pat. 8898 of 1893 (this Journal, 1894, 511), which referred to the production of di-alkylated naphthalene diamines by heating  $o$ - or  $\beta$ -naphthylamine sulphonic acids (more especially those containing the substituting groups in the meta position) with a primary amine and one of its salts, with or without the addition of benzoic acid. It has now been discovered that certain  $\alpha$ - and  $\beta$ -naphthol mono-, di-, and tri-sulphonic acids will react in the same way, giving di-alkylated naphthylene diamines or their sulphonic acids. Thus the (1.3)-diphenyl-naphthylene diamine described in Eng. Pat. 8898 of 1893 can also be obtained by mixing 1 kilo. of (1.3)- $\alpha$ -naphthol sodium sulphonate with 4 kilos. of aniline and 1 kilo. of aniline hydrochloride, and heating the melt to 150°–170° C. for about four hours, after which it is poured into dilute hydrochloric acid, when the diphenyl-naphthylene diamine separates out, and can be filtered off. The naphthol sulphonic acids suitable for this purpose are the following: (1.3)  $\text{C}_{10}\text{H}_7\text{OH}(\text{SO}_3\text{H})$ , of Ger. Pat. 37,910; (1.3.3') and (1.3.2')  $\text{C}_{10}\text{H}_6\text{OH}(\text{SO}_3\text{H})_2$ , of Ger. Pat. 38,281; (1.3.1')  $\text{C}_{10}\text{H}_5\text{OH}(\text{SO}_3\text{H})_3$ , of Ger. Pat. 45,776; (1.3.3'.1')  $\text{C}_{10}\text{H}_4\text{OH}(\text{SO}_3\text{H})_4$ , of Ger. Pat. 56,058; (2.4.1')  $\text{C}_{10}\text{H}_7\text{OH}(\text{SO}_3\text{H})$ , the acid C, of Ger. Pat. 65,997; and the hitherto unknown (2.4.2')  $\text{C}_{10}\text{H}_6\text{OH}(\text{SO}_3\text{H})_2$ , obtained by boiling the diazo compound or the corresponding  $\beta$ -naphthylamine disulphonic acid with water. The di-alkylated naphthylene diamines and their sulphonic acids produced as above are to be employed for the manufacture of dyestuffs by condensing them with

the nitroso derivatives of secondary or tertiary aromatic amines in a similar manner to that already described in Eng. Pats. 8898 and 11,892 of 1893 (this Journal, 1894, 511 and 631). The nitroso compounds can be replaced by other bodies which act in a similar manner, such as quinone dichloride and its analogues, and also certain azo compounds. Or, in place of these, alkylated *p*-diamines or their sulphonic acids may be oxidised together with the diphenyl-, di-*o*-tolyl-, or di-*p*-tolyl-(1,3,4')-naphthylene diamine sulphonic acid in presence of a suitable solvent by means of an oxidiser, such as ferric chloride, potassium dichromate, manganese dioxide, or the like.—T. A. L.

*The Manufacture and Production of New Colouring Matters and Leuco Compounds related to the Indigo Series, and of New Materials therefor.* B. Wilcox, London. From "The Badische Anilin and Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 17,472, September 16, 1893.

THE colouring-matters referred to in this patent are greenish-blue dye-stuffs which are carboxylated indigo derivatives. The leuco-compounds are obtained by fusing phenyl glycecol dicarboxylic acid with caustic alkalis. This new acid is produced by interacting with (1,2,3) amido-phthalic acid on chloro-acetic acid. The leuco-compound, when oxidised, gives a carboxylated indigo, which can be used as a dye, or sulphonated by treatment with sulphuric acid. About 125 kilos. of the sodium salt of (1,2,3) amidophthalic acid, and 58.5 kilos. of calcined soda are dissolved in 200 litres of water, then mixed with 120 kilos. of chloro-acetic acid, and the whole evaporated on the water-bath. The sodium salt of the phenyl-glycecol dicarboxylic acid so obtained is a syrup, which gradually solidifies. It is readily soluble in water, and dyes wool yellow from an acetic acid bath. In order to convert it into the leuco-compound, 1 kilo. is quickly added to 4 kilos. of fused caustic potash at 250° to 260° C., and kept at this temperature until the brown colour of the melt no longer increases in intensity. The melt, after cooling, is dissolved in 60 litres of cold water, and the leuco-compound may be precipitated by adding hydrochloric acid, but it is preferable to separate the colouring-matter directly, by adding ferric chloride. The dyestuff so formed is filtered off, and purified by dissolving in ammonia and precipitating with a mineral acid. In order to produce a sulphonic acid of this compound, 1 kilo. is dissolved in about 10 kilos. of fuming sulphuric acid, containing about 12 per cent. of anhydride. The melt is kept at about 65° C. for five hours, or until a sample is completely soluble in hot water. The melt is then poured into 100 litres of water, when part of the dyestuff separates, the rest being precipitated by adding salt. It is purified by dissolving in sodium acetate, and re-precipitating with a mineral acid. The sulphonic acid thus produced resembles indigo-carmin, but dyes wool from an acid-bath, giving rather greener shades. Still greener shades can be obtained by more energetic sulphonation by the use of sulphuric acid containing a higher percentage of anhydride.—T. A. L.

*Manufacture of New Violet, Blue, Grey, and Black Substantive Colouring Matters for Dyeing Cotton.* J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran, Basle, Switzerland. Eng. Pat. 9806, May 19, 1894.

THIS is an extension of Eng. Pat. 8511 of 1893 (this Journal 1893, 671), and also of Eng. Pat. 12,704 of 1893 (this Journal 1893, 824), describing the preparation of mixed tetrazo compounds from the unsymmetrical bases described in the second patent. Different colouring matters are produced according to the order in which the combination takes place, so that, whereas the colouring matter obtained by converting formaldehyde-dianisidine-aniline into its tetrazo compound, and combining it first with (1,4)-naphthylamine sulphonic acid, and secondly with (1,4)-naphthyl sulphonic acid dyes cotton a bluish violet shade, that obtained by carrying out the combination in the reverse order, gives reddish violet shades on unmordanted cotton.

Another series of colouring matters is produced by combining the tetrazo compounds of the symmetrical or unsymmetrical formaldehyde bases with (1,3,3',1')-amido-naphthol disulphonic acid or with (2,3',1') amido-naphthol sulphonic acid. The resulting colouring matters which dye cotton grey and bluish grey can be further diazotised and combined with amines and phenols and their sulphonic acids giving very dark shades. Thus the tetrazo compound from 3,4 kilos. of formaldehyde-tolidine-*o*-amido-phenol when combined with 4.8 kilos. of (2,3',1') amido-naphthol sulphonic acid in presence of sodium carbonate gives a colouring matter which dyes unmordanted cotton grey. After diazotisation and combination with *m*-phenylene diamine, the colouring matter dyes cotton a greyish black which, when dyed on 5 per cent. gives practically a black. (See also Eng. Pats. 20,301 and 20,790 of 1893, this Journal 1894, 32 and 146).—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Agave Americana Fibre.* J. Soc. Arts, 42, 702.

*Agave americana* grows in all soils in the Coimbatore district of the Madras presidency. This district has a mean temperature of 78°, with maximum and minimum temperatures of 97° and 64° respectively, and the annual rainfall is 21 inches, half of which falls during the monsoon (October to December).

The plant must be freely exposed to the sun, shade rendering it unhealthy.

The fibre is extracted, either by scraping or by maceration from the old green outwardly-drooping leaves of plants six or seven years old.

*Scraping process.*—Here, the spines, and about six inches of the apex of the leaf having been cut off, the leaf is split longitudinally into four or five pieces, which are next beaten with a mallet.

The "pulp" is then removed by a bamboo scraper and the fibre dried in the sun. This fibre, without either working or bleaching, is very clean, but the staple is not long. It is made into thread, which is used in weaving grass mats.

*Maceration process.*—The leaf is trimmed as before but not split. It is then beaten with the mallet and thrown, in bundles, into tanks, where it is left for 14–20 days, or until the pulp is quite decomposed. It is then taken out and exposed to the sun. The fibre so obtained is longer than, but not nearly so clean as that obtained by scraping.

If a demand arose, there would be a large supply, and then the present price of 2 annas per 1 lb. would no doubt be reduced.—E. R. B.

## PATENTS.

*An Improved Fabric for Garments.* F. Linneborn, Hagen, Germany. Eng. Pat. 12,390, June 23, 1893.

THE improvement claimed consists in knitting or manufacturing the fabric in two layers, the one of linen and the other of wool, flaked together, so that one side is entirely of linen and the other of wool. The layer of linen lying next to the skin keeps it cool, perspiration passing through the interstices between the linen fibres, because these do not absorb it, into the wool fibres, which first receive it and then allow it to evaporate immediately. In this way all drying of perspiration on the skin is avoided.

—E. G. P. T.

*Improvements in Apparatus or Machinery for Washing Wool or other Fibres.* J. Dawson, Rochdale. Eng. Pat. 13,874, July 18, 1893.

AN improved scouring apparatus is invented, in which the fibres are passed through the liquor by means of rakes,

forks, or prongs, mounted upon endless chains or bands, and the special object is to vary or regulate the angle of the rakes to the chains, particularly at the delivery end of the apparatus. To clean the bottom and sides of the wash bowl, a brush is employed, approximately of the size or shape of a cross-section of the bowl, and secured to one of the rakes.—E. G. P. T.

*Improvements in or applicable to Machinery for Securing and Washing of Wool and other Fibrous Materials.*  
J. and W. McNaught, Rochdale. Eng. Pat. 15,082, August 5, 1893.

An invention relating to improvements upon machines described in a former specification, Eng. Pat. 983, 1882, and involving the use of plates, grids, or sieves termed "immersers," which have perforated bottoms and turned-up sides and are made to sink into and rise out of the liquor in the trough in which the fibres operated upon are scoured.—E. G. P. T.

*Improved Treatment of Textile Fabrics for Stiffening same, and Production of Material suitable for Use as Tracing Cloth.* E. J. Goodwin, Castleton. Eng. Pat. 16,698, September 5, 1893.

The process of treating a textile fabric having a close texture, with sulphuric acid of 115 Tw. at a temperature of 64° to 65° F., as described in Eng. Pat. 22,566, 1892, is now extended to loose fabrics such as lace, and is found to impart to them a stiffness and finish that renders them suitable for use after washing and drying without the necessity of starching. Sheet material of a translucent character, suitable for tracing purposes, can also be produced by treating a finely woven cloth, such as lawn or muslin, with dilute sulphuric acid of 128—132 Tw. at a temperature varying between 64 and 72° F.—E. G. P. T.

## VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

*The Action of Light upon Dyed Colours.* Rep. of the Committee (T. E. Thorpe, J. J. Hummel, W. H. Perkin, W. J. Russell, W. de W. Abney, W. Stroud, and R. Meldola). Drawn up by J. J. Hummel. Brit. Assoc. Sect. B. Oxford. 1894.

DURING the past year the work of this committee has been continued, and a large number of wool and silk patterns, dyed with various natural and artificial orange and yellow colouring matters, have been examined with respect to their power of resisting the fading action of light.

The general method of preparing the dyed patterns, and the manner of exposing them under glass, with free excess of air and moisture, were the same as already adopted.

The patterns were exposed at Adel, near Leeds, in the grounds of James A. Hirst, Esq., to whom the best thanks of the Committee are again due for his kind permission.

Each dyed pattern was divided into six pieces, one of which was protected from the action of light, while the others were exposed for different periods of time. These "periods of exposure" were made equivalent to those adopted last year, by exposing, along with the patterns, special series of "standards" dyed with the same colouring matters as were then selected for this purpose. The standards were allowed to fade to the same extent as those which marked off the "fading period" of last year, before being renewed or removing a set of dyed patterns from the action of light. The patterns exposed during the past year are therefore comparable, in respect of the amount of fading which they have experienced, with the red dyes already reported upon.

The patterns were all put out for exposure on June 8, 1893, certain sets being subsequently removed on the following dates: July 1, July 31, August 26, 1893; February 19, June 12, 1894. Of the five "periods of exposure" thus marked off, periods 1, 2, 3 were equivalent to each other in fading power, whereas periods 4 and 5 were each equivalent to four of the first period in this respect; hence five patterns of each colour have been submitted respectively to an amount of fading equal to 1, 2, 3, 7, and 11 times that of the first "fading period" selected—viz. June 8 to July 1, 1893.

The dyed and faded patterns have again been entered in pattern-card books in such a manner that they can be readily compared with each other.

The following tables give the general result of the exposure experiments made during the year 1893-94, the colours being divided, according to their behaviour towards light, into the following five classes: very fugitive, fugitive, moderately fast, fast, very fast.

The initial numbers refer to the order of the patterns in the pattern-books. The S. and J. numbers refer to Schütz and Julius's "Tabellarische Uebersicht der künstlichen organischen Farbstoffen."

The colours marked thus (\*) appear to be somewhat faster than the rest of the class in which they are placed.

In the case of colouring matters requiring mordants, the particular mordant employed is indicated in brackets after the name of the dye-stuff.

### CLASS I. VERY FUGITIVE COLOURS. (Wool.)

The colours of this class have faded so rapidly that at the end of the first "fading period" (June 8 to July 1, 1893) only a very faint colour remains, or it has become very materially altered in hue. At the end of the fifth period (one year) all traces of the original colour have disappeared, the woollen cloth being either quite white or merely of a yellowish or brownish tint.

Mordant Colours. 1. Young Fustic (Al.). Wood of *Rhus cotinus*.  
8. Tesu (Al.) Flowers of *Butea frondosa*.

NOTES.—Certain of the nitro colours show extreme sensitiveness to light by rapidly altering in hue. During the first "period of exposure," the rich red-orange colour of Aurantia, for example, soon changes to brown, and the pure lemon-yellow of Pieric Acid changes to orange-yellow; in both cases these altered colours fade slowly without any further change in hue, and might almost be placed among the "moderately fast colours." Brilliant Yellow, Martins Yellow, and Naphthol Yellow S behave somewhat like Pieric Acid, but the alteration in hue is much less pronounced. Thiazol Yellow, Mimosa Yellow, Thioflavin T and S, and Primulin all fade rapidly during the first "period of exposure" to a yellow-buff, which then appears to be "moderately fast."

## CLASS II. FUGITIVE COLOURS. (WOOL.)

The colours of this class show very marked fading at the end of the second "fading period" (July 1 to July 31, 1893), and after a year's exposure they have entirely faded, or only a tint remains.

*Azo Colours.*

8. Cloth orange. From benzidine, salicylic acid, and resorcinol. S. and J. 170.

*Quinoline Colours.*

- Acid Colours. 41. Quinoline Yellow S. Sodium salt of quino-tha'one-disulphonic acid. S. and J. 379.

*Natural Colouring Matters.*

- Wool Book IV.  
Mordant Colours. 1. Tesu (Cr.).  
3. Young Fustic (Cr.).  
15. Anthracine (Cr.). Composition not published.  
2. Quercitron Bark (Al.). Bark of *Quercus niger*.  
3. Old Fustic (Al.). Wood of *Morus tinctoria*.  
6. Flavin (Al.). Quercetin prepared from Quercitron Bark.  
7. Persian Berries (Al.). Fruit of *Rhamnus saxatilis*.  
2. Persian Berries (Sn.).  
3. Young Fustic (Sn.).  
4. Flavin (Sn.).  
5. Quercitron Bark (Sn.).  
6. Old Fustic (Sn.).  
7. Tesu (Sn.).

NOTES.—The fugitive character of Narcein as compared with Orange II., of which it is merely the sodium bisulphite compound, is very pronounced. The bright orange of Flavin with tin mordant changes rapidly during the first exposing period to an olive-yellow, which may be regarded as "moderately fast." A similar change is noticed in the case of Quercitron Bark and Old Fustic with the same mordant, the faded colour of the latter being, however, very dull.

With aluminium and tin mordants Anthracine gives bright but very fugitive colours.

## CLASS III. MODERATELY FAST COLOURS. (WOOL.)

The colours of this class show distinct fading at the end of the second period (July 1 to July 31, 1893), which becomes more pronounced at the end of the third period (July 31 to August 26, 1893). A pale tint remains at the end of the fourth "period of exposure" (August 26, 1893, to February 19, 1894), and at the end of a year's exposure the colour has entirely faded, or, at most, mere traces of colour remain.

## Natural Colouring Matters.

## Wool Book IV.

- Mordant Colours. 5. Weld (Al.). *Reseda luteola* (whole plant).

NOTES.—The following colours become somewhat duller and apparently darker during the first and second periods of exposure:—Diphenylamine Orange, Metanil Yellow, Fast Yellow N, Azo-flavin S, Acid Yellow OO, and Aurotin. This appearance is only observed when the patterns are examined “underhand,” i.e., by looking down into the fabric; when they are examined “overhand,” i.e., by glancing along the surface, a normal fading of the colours is observed. This darkening is probably due to the presence of the diphenylamine group in the first four colours mentioned, and to the presence of the nitro group in the case of Aurotin, of which the alteration in hue reminds one of the change occurring in pieric acid yellow, though it is less pronounced.

Mordant Yellow with aluminium and tin mordants gives colours which may well be classed with the fast colours.

## CLASS IV. Fast Colours. (Wool.)

The colours of this class show comparatively little fading during the first, second, and third periods. At the end of the fourth “period of exposure” a pale shade remains, which at the end of the year’s exposure still leaves a pale tint.

## Natural Colouring Matters.

- Mordant Colours. 2. Persian Berries (Cr.). S. Weld (Sn.).

NOTES.—In Palatine Orange we meet with the first example of a colour fast to light, the manufacture of which

has already been abandoned; possibly some difficulty or expense connected with its manufacture may account for this circumstance.

Yellow for wool AF, applied with aluminium mordant, is very fugitive, while Chrome Orange seems quite as fast as with chromium. Chrome yellow with aluminium mordant may be classed as a "moderately fast" colour.

Gallodavin with aluminium and tin mordants gives fugitive colours, more especially with aluminium.

#### CLASS V. VERY FAST COLOURS.

The colours of this class show a very gradual fading during the different periods, and even after a year's exposure a moderately good colour remains.

" 16. \*Xanthanin (Cr.). Composition not published.

NOTES.—The brownish-red given by Alizarin Orange W with chromium mordant becomes, during the first "fading period," distinctly bluer in shade, and hence apparently darker; the altered colour then fades so slowly that even after a year's exposure the faded colour appears almost as dark as the original.

The azo colours in this class which have been dyed on chromium mordanted wool leave, at the end of a year's exposure, faded colours of greater body and fulness than those applied without mordant; this is no doubt due to the inferior fastness of the latter, the faded colours of which are covered with a thin layer of perfectly bleached fibres.

All the artificial azo-mordant-colours in this class were fixed with aluminium as well as chromium mordant, and found to be equally fast to light. They were also applied with a tin mordant, but only in a few cases were satisfactory level colours thus obtained, and these seemed to be inferior to those applied with an aluminium mordant, in point of brilliancy as well as of fastness to light.

#### SILK PATTERNS.

Most of the foregoing colours were also dyed on silk, and the patterns were exposed to light along with those on wool. The relative fastness of the various colours was, for the most part, the same as on wool, the differences observed being too unimportant to necessitate a special classification for silk. In Class IV., Yellow for wool AF (Cr.) proved to be much more fugitive on silk, whereas Chrysamin R and G, Titan Yellow R and Y, Oriol, Cresotin Yellow R and G, and Chrysophenin appeared to be somewhat faster. In Class III. the same remark applies to Cotton Yellow G.

The Indian dyestuff Kamala was an additional one applied to silk, and found to belong to the fugitive class, being very little faster than Annatto.

#### GENERAL OBSERVATIONS.

The first thing which strikes one when examining these orange and yellow patterns is the comparatively large number of satisfactorily permanent colours.

In the more or less fugitive class are to be found all the basic colours, all the nitro-phenols, with the exception of Palatine Orange, and all the bright yellows derived from the natural colouring matters by means of aluminium and tin mordants, with the exception of those obtained from Weld. Comparatively few azo colours are met with in this group.

The marked alteration in colour from yellow to orange shown in the case of picric acid has long been known, and is ascribed to a reducing action of the light. The equally striking change from orange to brown, shown by Aurantia, does not, however, seem to have been previously recorded.

By far the largest number of yellows, ranging from "moderately fast" to "very fast," are to be found among the azo colours. Specially important are those in which salicylic acid is a constituent element, since not only does this impart to the colour the power of forming more or less stable lakes with chromium and aluminium mordants, but it appears frequently to give the colours the quality of fastness to light, even when no mordant is applied. It is a fact of some importance that the colours obtained with aluminium are practically as fast as those fixed with chromium, since the first-named mordant gives much brighter and purer yellows. The tin mordant, so useful in the production of the most brilliant orange and yellow colours obtainable from the natural colouring matters, seems, however, to be of little or no advantage in connection with most of these azo-mordant-colours, no doubt because they are susceptible to the reducing action of the mordant usually employed for wool—viz., stannous chloride.

Very interesting in point of fastness to light are the azoxy colours, and although unfortunately apt to dye wool somewhat irregularly, giving speckled-looking colours, they are admirably adapted for silk and cotton.

Another interesting little group is that which includes Tartrazin, a colour not only noteworthy for its fastness to light, but also because of its brilliancy and purity.

The fastness of alizarin orange is worthy of special mention, for it is probably greater even than that exhibited by most other colours of the alizarin group, and it shows the peculiar darkening action exerted by the light, probably in consequence of the presence of the nitro group.

It is remarkable how few really fast yellows are derived from the natural colouring matters, and these are chiefly

the olive-yellows obtained with chromium mordant. The only fast, and at the same time bright, natural yellows are those derived from Weld, and since this dye-stuff is now of little general importance to the dyer its cultivation has become extremely limited, and is gradually being given up; it is fortunate therefore that science has been able to replace it by efficient substitutes, so far, at least, as permanency towards light is concerned.

Our experiments have already abundantly proved that the popular opinion that the coal-tar dye-stuffs include only such as yield more or less fugitive colours is entirely false; indeed, it is perfectly safe to assert that coal-tar is the source from which the greatest number of colours fast to light are derived at the present time, and this seems to be specially true of the red and yellow colours.

*On the Influence of the Structure of the Textile Fibres upon the Absorption of Colouring Matters.* G. V. Georgievics. Mitt. k.k. Tech. Gew. Museums, 1894, 4 (4, 5 and 6) 163.

THE influence of the structure of the textile fibre upon the behaviour of the latter in the process of dyeing, has never been investigated, although it is well known that different kinds of wool show marked differences on dyeing, which is also the case with the various cellulose fibres, particularly flax, which are much more difficult to dye than cotton. Of the various fibres, cotton being most easily obtainable in a structureless "disorganised" form, the experiments were first tried with this material. The "disorganised" cellulose was prepared by dissolving Swedish filter paper in Schweitzer's reagent, and reprecipitating with an acid. The cotton used was pure surgical wadding. The dyes employed were benzopurpurin 4 B and benzoazurin G, the first being chemically pure, the second of 75 per cent. strength. All the dye-trials were made simultaneously, and under the same conditions, so that the colorimetric examination of the residual dye-baths at once revealed which of the two forms of cellulose employed, had taken up more of the colouring matter. Carrying out these experiments with benzopurpurin, cotton was found to absorb more of the dye than precipitated cellulose, whilst in the case of benzoazurin the latter took up as much, or but very slightly less than the former. On a similar experiment with methylene blue, the cotton had absorbed distinctly less of the dye than the precipitated cellulose, but the latter was again found to take up less tannic acid than the former. These results are therefore not available for any definite conclusions regarding the influence of structure upon the absorption of colouring matter. It is possible that the solution of the cellulose in the ammoniacal solution, is accompanied by some chemical change, so that the structureless body precipitated from this solution by acids cannot be considered the chemical equivalent of ordinary cotton. A repetition of these experiments with mercerised cotton and precipitated and mercerised cellulose, revealed the fact that the former absorbed much more dye than the latter. In all cases the dye was found to be much better fixed by the cotton than by the precipitated cellulose. In order to test wool in a similar manner, weighed quantities of wool and wool dust prepared from loose wool, were dyed under the same conditions with cyanine B. The powdered wool was found to absorb much less dye than the ordinary wool fibre, and also in this case the dye was faster to washing upon the latter. Soft, woolly asbestos fibre was converted into a fine powder, and both fibre and powder were dyed with benzopurpurin under the same conditions. The result of this experiment showed that powdered asbestos takes up very small quantities of benzopurpurin, while fibrous asbestos absorbs even more of the dye than mercerised precipitated cellulose. Altogether these experiments prove that the fibrous structure of textile materials not only favours the absorption of larger quantities of dyestuff, but also favours the better fixation of the latter upon them.—C. O. W.

*A New Compound for the Production of Indigo upon the Fibre.* G. Ulrich. Mitt. k.k. Tech. Gew. Museums, 4, 1894 (4, 5 and 6) 182.

KARL'S "indigo salt," the sodium bisulphite compound of ortho-nitrophenyl ketotone—

is sold as a paste which is easily soluble in cold water. On heating it above 50° C., the free acetone separates out. On adding alkalis to its aqueous solution indigo is readily formed. For practical purposes a solution of caustic soda of 28 B<sup>e</sup> (14.47 per cent. NaOH) was found especially suitable, but to avoid mercerisation, solutions of from 16 to 18 B<sup>e</sup> (10 to 12 per cent. NaOH) are often used. In printing, the cloth is either padded with the solution of the indigo salt, and the pattern produced by printing with a mixture of 500 parts of British gum thickening, and 350 parts of caustic soda at 40 B<sup>e</sup> (35 per cent. NaOH), or the solution of the indigo salt is suitably thickened, printed on the calico, and the latter subsequently passed through caustic soda. The pieces padded or printed with indigo salt should not be exposed to light before developing the blue. After developing, the pieces are washed, soured, again washed and dried. The blue obtained is of a fine shade and very fast to rubbing. From 20 to 25 grms. of indigo salt per 1,000 cc. of padding liquor or printing colour produce light blue, from 200 to 300 grms. dark blue. Addition of neutral salts to the caustic soda, although minimizing its mercerising influence is detrimental to the blue. Schlieper and Baum's well known Turkey-red discharge styles on indigo, may be produced with this indigo salt, by padding the oiled cloth with a mixture of aluminium bisulphite and indigo salt, and drying. On subsequent printing with caustic soda, discharge of the alumina mordant and development of the blue take place simultaneously, and the Turkey-red is subsequently produced upon these pieces in the usual manner, or Turkey-red cloth is padded with the indigo salt, dried, printed with caustic soda, dried, steamed, soured, washed, soaped, again washed and dried. The last-named method is also applicable in combination with all those dyes, the lakes of which are not decomposed by caustic soda, or the pieces may be prepared with naphthol, and printed with a diazo-compound and indigo salt simultaneously, dried and passed through caustic soda. Combinations with tannin lakes are obtained by padding with a mixture of tannic acid and indigo salt, drying, printing with caustic soda, passing through tartar emetic, washing and dyeing with a basic dye. Also combinations with "Oxidation aniline-black" are possible, and many others.—C. O. W.

## VII.—ACIDS, ALKALIS, AND SALTS.

*The Manufacture and Refining of Carbon Bisulphide at Zalatna (Hungary).* J. Farbaký. Zeits. angew. Chem. 1894, 226—231.

CASE-IRON retorts *a* (Figs. 1 to 3) of elliptical section, 36 in. by 20 in., and  $1\frac{1}{2}$  in. thick, are used. They are provided with a jacket of refractory material, in which near 4 in. flues *b* (Fig. 1) are arranged to ensure the uniform heating of the retort. The part *γ* of the brickwork also consists of refractory material (firebricks), the rest of ordinary bricks *δ* (Figs. 1 and 3). The openings at *b*, through which the coal is fed into the retorts, are provided with lids and water-joints. The sulphur is added through the openings at *c*, while the openings *d* serve for the cleaning out of the retorts. The firebars are arranged as shown at *r* (Fig. 1), the flue gases passing through *f* into the chimney (Figs. 2 and 3). The iron retorts before being brought into use are lined with a refractory coating by placing within them a jacket of sheet iron of about 2 in. less diameter than that of the retort. The annular space between jacket and retort is then filled with a warm liquid mixture of the dust of fireproof bricks and treacle. To prevent warping or bending outwards of the sheet iron, it is supported by wooden wedges or blocks. The inner space of the jacket is then filled with medium-sized pieces of limestone and the retort heated for two or three days. After this time the refractory lining is converted into a hard mass, and the wooden wedges often charred. The lime is then removed without disturbing the iron jacket which is readily destroyed in the first working of the retorts, when its *débris* and that of its supports can be removed. Each of these retorts has an average lifetime of eight months, during which it produces about 86 tons of carbon bisulphide. If the retorts are not provided with the refractory lining described, they only last from  $1\frac{1}{2}$  to 3 months. (See this Journal, 1889, 118.) When used for the first time the retorts are moderately heated for about 12 days, and are then filled through the opening *b* with pieces of charcoal about 2 in. in diameter. The heat being now raised, and whilst fumes appear at the end of the condenser, sulphur is added through short funnel-shaped tubes placed in openings *c* (Fig. 1). The sulphur is added in powder or in lumps of about  $\frac{1}{2}$  in. diameter.

Fig. 1.

The openings *c* are then closed with clay plugs. For every 90 lb. of charcoal contained in the retorts 40 lb. of sulphur are added, and this weight of sulphur produces from 250 to 300 lb. of crude bisulphide. The charcoal used, before being added, is well dried and ignited. Nevertheless it still contains hydrogen and oxygen, which in the process cause formation of sulphuretted hydrogen and other gases. Charcoal made from beech-wood is preferable to that made from pine wood, since owing to its higher specific gravity the retorts will hold more of it and consequently require fewer charges. This means a considerable saving of time, as two hours before adding fresh charcoal, the feeding of sulphur into the retort is stopped in order to have all the sulphur in the retort converted into bisulphide, and so to prevent losses while the charcoal is being added. The daily working of

the retorts is carried on in the following manner:—The retorts are filled with charcoal (which takes about five minutes), they are then heated for two hours without adding any sulphur. Next the sulphur is fed in—a process continuing for the next 20 hours. Two hours before adding another charge of charcoal the feeding in of the sulphur is stopped. Throughout these 24 hours the temperature of the retort is maintained evenly at bright redness. Five men attend to two furnaces. At least once every fortnight the retorts are cleared of ashes and coal dust. During this operation tube *d* connecting the retort and condenser is closed with a plug to prevent

Fig. 2.

possible explosions. The waste charcoal withdrawn from the retorts is allowed to fall into water to prevent the bisulphide contained therein, from evaporating. It is then dried and sieved and used over again. The condensation of the carbon bisulphide takes place in the bell-shaped receivers *k* (Figs. 2 and 3) which are arranged in a pan *l* filled with water and acting as a condenser. These receivers, of which four are used for each retort, have a capacity of from 0.32 to 0.384 cubic metres. They are provided with

Fig. 3.

lids of from 20 to 40 cm. diameter, resting in water-lute grooves, which are, however, filled with a mixture of water and fine sand. The bisulphide distils from the retort through the pipe *d* into the condensers *k*. Any vapours not condensed there, first pass through the boiler-shaped vessel *n*, which is about 9 ft. long and 2 ft. in diameter, and travel then through three U-shaped tubes which are kept cool in a water-tank. From these tubes a pipe is

carried into the open air, with a downward bend at its end, and a zinc jug is placed underneath it in order to collect

any bisulphide which might have escaped. The bisulphide in the morning of each day is drawn from the pan *l* of the condensers and stored in iron tanks. Of the difficulties encountered in this branch of manufacture requiring special mention, the clogging up of the tube *d* by sulphur distilling over with the bisulphide, often causes interruption in the working. Experiments with retorts of different slopes and materials showed that distillation of sulphur occurs in the case of every kind of retort. To prevent explosions in attempting to remove distilled sulphur from the pipe *d* or the first condenser during the working of the retort, the pipe *d* is heated from the outside. The molten sulphur then flows into the first condenser and the pan *l*, from which it can be removed. To obtain the best results from the charges, the distillation should be conducted throughout at a bright red heat, *i.e.* about 1,000 °C. The following tables show the working results obtained:—

Year.	12 Hour Shift.	Charges.						Yield.			Fuel & Wood used.			Cost of Pro- duc- tion of 1 Hk. of CS <sub>2</sub> .	Cost of Total Produc- tion.

The crude bisulphide contains from 6 to 10 per cent. of dissolved sulphur. It possesses a brownish colour and penetrating smell. It is purified by distillation from an iron still *y* (Fig. 4), 6 ft. high and about the same in diameter. The still is enclosed in a wooden jacket and the space between filled with cinders. The distillation temperature of 48° C. is raised by means of steam injected into the space under the still, forming a false-bottom *f*<sup>1</sup>, or by an improved process it is passed through *f*<sup>1</sup> and the pipe *h* directly into the still *y*. The bisulphide vapours pass through *x* into a system of four U-tube condensers, the distillate being collected under water. *z* is an opening for filling as well as for cleaning the still. The still being charged with from 40 to 45 hk. of crude bisulphide, steam at about 8 lb. pressure is admitted into the jacket. Two hours afterwards the distillation begins, preceded by a hissing noise, due to the rush of sulphuretted hydrogen which is at first evolved. The distillation takes about six hours. The removal of the residual sulphur from the still is a very disagreeable operation, resulting in suffering to the workmen from headache, vomiting, fits of weeping, pains in the limbs, general weakness of body and mind, and especially loss of memory. These affections may develop into actual insanity. To protect the workmen from the bisulphide vapours, the still *y*, after the distillation, is filled three-fourths full with water, and the latter is heated to boiling by means of directly injected steam, which is admitted through *h*. After about 20 hours' boiling all bisulphide is driven off, and the sulphur is now easily removed from the still. This recovered sulphur is subsequently used again in the manufacture. The bisulphide drawn from the condensers is stored under water in iron tanks holding from 30 to 80 hk. of it. It is sold in iron drums holding 100 or 500 kilos. each. In the former 12, in the latter 2'5 litres of air-space are allowed for the expansion of the carbon bisulphide.—C. O. W.

*The Function of Calcium Chloride, and the Formation and Constitution of the "Stiff Charges" in the Weldon Manganese Recovery Process.* J. Wiernik. Zeits. angew. Chem. 1894, 257—263.

It is well known that the addition of more than 1'5 mols. of lime to every mol. of manganese chloride greatly facilitates the oxidation of manganese solutions by means of air. The drawback of using an excess is that such large quantities of lime are likely to produce stiff charges. It is here that the beneficial influence of calcium chloride comes in. Solutions containing 2'5 to 3 mols. of calcium chloride may be safely treated with the above excess of lime, and the resulting mud will be better oxidised without having recourse to excessive blowing, and settles better than mud obtained under other circumstances. The explanation of the process cannot be given with certainty. The explanation propounded by Lunge and Zahorsky (this Journal, 1892, 882), in which stress is laid on the solvent action of calcium chloride on lime and manganese peroxide, and on the more rapid formation of calcium manganite from such a solution by the action of air, is likely to be the correct one.

Determinations of the relative quantities of calcium chloride and lime which may be present in a manganese chloride solution without producing stiff charges, show that at a temperature of 60 °C. the quantity of calcium chloride should not fall below 2'4—2'5 mols., and the lime ought not to exceed 1'7 mols. for every mol. of manganese chloride.

It is not new to practical men that the setting of the stiff charges in the oxidisers may be avoided by powerful blowing. The author fixes the period at which the charge is likely to stiffen, at the beginning of the oxidation process, and finds that the danger is great before the lapse of 1½ hours after completed precipitation of the manganese hydrate. At this juncture 30—35 per cent. of the manganese is oxidised; but the greatest danger may be expected

with an oxidation of 35–39 per cent. When the oxidation has advanced to 55–65 per cent., the conditions for a stiff charge are no longer present.

Judging from the period of its formation, the proportion of  $\text{MnO}$  to  $\text{MnO}_2$  in a stiff charge is 2 mols. of the former to 1 of the latter, or perhaps 5:3. Lime will be also among the constituents, but not calcium chloride or calcium oxychloride, as assumed by Post. The determination of the composition of a stiff charge by means of analysis is a difficulty which the author has not surmounted to his own satisfaction. As a likely composition he mentions 41.64 per cent.  $\text{MnO}$ , 25.51 per cent.  $\text{MnO}_2$ , 32.85 per cent.  $\text{CaO}$ , equal to  $2\text{MnO} \cdot 1\text{MnO}_2 \cdot 2\text{CaO}$ , or to  $\text{Mn}_2\text{O}_3 \cdot 2\text{CaO}$ .—H. A.

*The Decomposition of Tartaric and Citric Acids by Sunlight.* W. Seekamp. *Annalen*, **278**, 373–374.

LIEBIG observed that manganese peroxide decomposes a tartaric acid solution with separation of carbonic acid and a substance which reduces cupric salts, that malic acid when similarly treated yields aldehyde and carbonic acid, and citric acid forms acetone and carbonic acid (*Annalen*, **113**, 1). The author has investigated the action of sunlight on solutions of two of these acids, containing in addition uranium oxide, and finds that a decomposition similar to that observed by Liebig occurs after an exposure of several months. In the case of the tartaric acid, the solution contains 5 per cent. of the acid and 1 per cent. of uranium oxide. It is noticed that shortly after insolation, gas is evolved, and the liquid becomes green owing to the reduction of the uranium oxide. After several months the solution was distilled, and the distillate contained aldehyde. After removing the aldehyde, the solution showed an acid reaction, and was neutralised with freshly precipitated lead hydrate, which, on decomposition with sulphuretted hydrogen, yielded unaltered tartaric acid, malic and succinic acids. The mother-liquor, after removing the excess of lead, reduced cupric salts, but no definite compound having this property could be separated from the solution. A barium salt obtained from the solution consisted probably of propionic acid, but the quantity was too small for analysis. The author considers that the reaction takes place as follows:—Tartaric acid is decomposed first into oxalic acid and a substance,  $\text{C}_4\text{H}_4\text{O}_2$ , which reduces cupric salts. The oxalic acid then splits up into carbonic acid, carbonic oxide, and water, and the carbonic oxide liberated reduces the tartaric acid to malic acid, and this further to succinic acid; at the same time part of the malic acid decomposes into aldehyde and oxalic acid, and the succinic acid gives propionic acid and carbonic acid.

The same phenomena are observed in the case of solutions of citric acid containing uranium oxide. Gas is evolved, the solution becomes green and has a peculiar smell, and gives, after several months, acetone on distillation. The decomposition is represented by the equation—

but the further products of the reaction have not been investigated.—T. A. L.

## PATENTS.

*An Improved Method of and Apparatus for Producing Carbonic Acid Gas.* H. Lane, Birmingham, and J. Pullman, London. Eng. Pat. 12,995, May 3, 1893.

Air is passed into an iron-lined clay retort, set vertically in a heating chamber, and charged with charcoal. The carbonic oxide produced passes through a valved tube into a horizontal retort, heated by gases from the first-mentioned heating chamber, so as to traverse a layer of copper oxide (for instance). The outlet tube for the carbonic acid gas formed, has a valved outlet to the air, beyond which it is connected to a blower, and the outlet tube from this has set into it a tube leading back to the vertical retort. The inventors allege that when the carbonic oxide is converted into carbonic acid by passing through the copper oxide, it is "considerably amplified in volume, the relative proportion of nitrogen being lessened." Part of the gas is allowed to escape into the air, and "the remainder of the mixture is forced back to and through the first retort."

—E. S.

*Improvements in or connected with Apparatus for the Manufacture of Chlorate of Potash by Electrolysis.* T. Hurter, Liverpool. Eng. Pat. 15,396, August 12, 1893.

The solution of potassium chloride is electrolysed in a metallic vessel, which forms the cathode. This is coated inside with a mixture of Portland cement, salt, sand, and water, which forms a porous diaphragm. The anode consists of a sheet or sheets of platinum. The cells so arranged may be connected in series or used separately.

*Improvements in or connected with Pumping and Absorbing Chlorine Gas, and Apparatus for use therein.* P. J. Worsley, W. Windus, and B. Bracey, Bristol. Eng. Pat. 16,151, August 26, 1893.

CHLORINE, and especially dilute chlorine, such as that resulting from the "Deacon" and other processes, is well dried before presenting it for absorption by milk of lime or other agent, since the inventors have found that chlorine gas in a dry condition, does not act readily on ordinary metals, and can therefore be pumped by an ordinary air-compressor.

The chlorine is passed through a lead or earthenware vessel charged with coke or the like, over which a flow of sulphuric acid is maintained. The gas has exit through a liquid seal, at the upper part of the desiccator, into a pipe connected to a pump of ordinary construction, which, as well as the inlet and outlet valves, may be made of metal. Or the pump cylinder and piston may be lined with ebonite, and india-rubber valves may be used. The lubricator should be a pure mineral oil not acted upon by chlorine gas. The pipes and distributor may be of cast iron or earthenware. The distributor, placed near the bottom of the absorbing tank, is a system of pipes, slotted on the under side, so that the gas may rise through the absorbing liquid in bubbles or fine streams. An agitator is provided.—E. S.

## VIII.—GLASS, POTTERY, AND ENAMELS.

### PATENTS.

*Improvements in the Manufacture of Earthenware or Porcelain Filters and Analogous Articles.* A. da S. Prado, Paris, and B. Medina-Santurio, Houilles, France. Eng. Pat. 14,132, July 21, 1893; date of first foreign application, February 17, 1893.

THE inventors have departed from the ordinary method of moulding or casting filters and analogous articles, and in lieu of such processes they compress the materials of which the articles are made round a core of fusible material, such as a metallic alloy. The core is provided with three or more projections, which serve to keep it in place and which provide a channel of escape for the fusible material of which the core is composed, when the article is placed in the furnace. The materials used for the filter or other analogous article are such as are usually employed, e.g., kaolin, clay, asbestos, and the like. The materials are compressed in a moist state, but not in the condition of a paste. The core may be composed of various materials, almost anything which melts or vaporises or burns away when heated may be employed, provided that it be practically incompressible. Besides alloys, sawdust with gelatin, charcoal, and even ice are described as suitable materials.—V. C.

*Process of Producing Intensely-Brilliant Pictures, Ornamentations, Inscriptions, or Drawings by Colour-Printing on Glass, and with a Backing Stamped in Relief.* A. Gortitz, Zürich. Eng. Pat. 7844, April 20, 1894.

THE design or inscription is first engraved on a printing-plate, for which rubber is a suitable material; the design being engraved *positively*, that is to say, in the same way as that in which it will be afterwards seen. The plate is then coated with varnish colour, and pressed upon a glass plate. The glass plate is strewn with bronze-powder, sheet aluminium, or other suitable material, the portions forming the design or inscription remaining empty, and being therefore transparent. The glass plate is then placed in a frame having a backing of strong paper-board, on the front face of which is mounted a brilliant sheet of tinfoil or tinplate, provided with prominent squares placed in suitable positions. The design is thus shown by a brilliant reflected light visible through the transparent part of the glass, the other portion of the glass forming a backing stamped in relief.—V. C.

*Improvements in the Production of Enamelled Letters and Designs on Glass, Porcelain, Stoneware, and other Surfaces.* C. Hodan, London. Eng. Pat. 11,513, June 12, 1894.

HERETOFORE raised enamelled writing and designs in relief on glass have been produced by means of a brush and thin enamel-paint. The inventor uses stencil-plates, preferably

of tinfoil or other flexible material, and a composition made of glass-powder, made up to the consistency of treacle with turpentine and "glaze." The composition is applied with a spatula through the openings of the stencil-plates, and the article is then fired. If the surface on which the design is to be produced is irregularly curved, or is curved both ways, the stencil is applied to sized paper, and the design is transferred from the dampened paper to the glass or ware. —V. C.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Asphalt Paving.* Report to the Department of Public Works, Philadelphia, U.S.A. 1894. (This Journal, 1893, 265.)

See under III., page 796.

### PATENTS.

*New or Improved Process or Means for Connecting Metal to Earthenware or China.* W. B. H. Drayson, London. Eng. Pat. 23,651, December 8, 1893.

THE process is applicable more particularly to the connection of lead pipes with the earthenware of closet basins or lavatory basins. The portion of the earthenware with which connection is to be made being unglazed, or the glaze having been removed, it is coated with plumbago, and placed in an electrolytic bath, whereby a firm metallic coating is obtained. The lead pipe is then soldered to this coating by a plumber's "wiped" joint. By this means are avoided the imperfect joints made with india rubber sleeves, washers, or putty.—V. C.

*Artificial Lumber or Composition Material.* J. C. Fell. From C. A. Smith, Minneapolis, U.S. Eng. Pat. 6678, April 3, 1894.

THE new material is produced in the form of boards of great strength, inflexible, and suited for all climates, not swelling or warping, and capable of taking a high polish. The boards are made up of layers of paper and wood, secured by adhesive material. The central strip or body of the board consists of sheets of wood laid end to end, above and below which are thinner sheets or veneers of wood having the grain transverse to the direction of the grain of the thicker sheets. The thinner sheets or veneers are provided with serrated edges, which provide a large surface for the thin and even spreading of a quick-drying adhesive material, which serves to weld the whole into a firm mass. On either side of the nucleus or body, consisting of the "sheets" and the "veneers" of wood, are thick sheets of paper, thick heavy straw- or pulp-board. Before using, the whole is subjected to great pressure, thereby disseminating the adhesive material, and subsequently dried and heated in a kiln. The finished material, although inflexible, can be worked by ordinary carpenter's tools.

By the employment of suitable materials, the composite board may be made waterproof, or fire-proof, or both.

—V. C.

*Improvements in the Manufacture and Treatment of Fire-proof Plastic Material for Cement.* R. Stone. Eng. Pat. 8549, April 30, 1894.

THIS improvement relates to a process described in Eng. Pat. 16,789, 1890 (see this Journal, 1891, 932), and consists in adding pearlsh, potash, soda, or sodium silicate to the petroleum or other inflammable oil which is used as a flux in the manufacture of the cement. About 7 cwt. of the

pearlash. No. is mixed with 1 cwt. of the flux, and the whole is then mixed with about one ton of the raw material, which consists of granite, slate, shale, clay, or similar substances.—V. C.

*An Improved Process of Manufacturing Porous Bricks.*  
H. Maurer, New York. Eng. Pat. 9948, May 22, 1894.

Porous bricks have formerly been made from clay and straw, but the inventor finds that a better quality is produced by employing the dung of animals which feed upon straw or hay. Equal parts of dung and clay make a good hard brick; five parts of dung to three of clay make a good soft brick.

The improved brick has strength sufficient for use in all the ordinary ways, and is especially adapted for fire-proofing and for interior use in all places where nails and screws are needed.—V. C.

## X.—METALLURGY.

*The Austin Process for the Treatment of Pyritic Minerals by Fusion.* Bull. Soc. Chim. 11, 1894, 448.

THE precious metals are often associated with sulphurous ores, especially in minerals obtained from deep mines, and such minerals often lend themselves, where the accompanying sulphides are those of copper, lead, or iron, or where these may be cheaply added to the mineral, to a fusion process, by means of which a *matte* of sulphides may be obtained; such *matte* collecting the precious metals, formerly diffused over a large bulk of ore, into a relatively small bulk. In this way many ore-deposits—for example, several in Transylvania, Sweden, and North America, which are either refractory, relatively poor, or remote as to locality—may be concentrated into a bulk capable of justifying the cost of transit to a metallurgical centre, and so be utilised.

At the present time this production of *matte* is always accomplished by aid of heat derived from the burning of coke, charcoal, anthracite, &c., the price of which therefore dominates the problem.

Mr. Austin proposes to employ as source of heat, elements other than carbon, and which are to be found in the mineral itself or in others in the immediate locality; for example, by means of pyrites only as fuel, he smelted *matte* from the refractory argentiferous and auriferous quartz ores of Colorado, Montana, and Arizona, which he was able to send to New York, Baltimore, &c., to be worked up.

The possibility of this procedure has been questioned, for it has been pointed out that iron pyrites ( $\text{FeS}_2$ ) only yields 2,253 calories, and copper pyrites but 1,700.

Mr. Austin's reply to these criticisms has been reproduced in the *Berg u. Hüttenm. Zeit.*

Iron, sulphur, and arsenic give out light and heat during oxidation, if the duration of the reaction is sufficiently shortened; there is therefore no reason why pyrites—a compound, as it is, of two combustible bodies—should not, with suitable plant, furnish the heat necessary in metallurgical operations; similarly, both blende and galena may be employed. The *rationale* of the operation is as follows:—Iron sulphide, burning at a high temperature, in presence of strongly heated silica, yields a very fusible slag of ferrous silicate, while the excess of the sulphides produces a *matte* which collects the gold and silver. The necessary attendant conditions are: a sufficiently high temperature at the tuyères; sufficient amount of hot air-blast to prevent chilling the furnace; a sufficiently open charge to allow of free circulation of the blast. The furnace is therefore peculiar from the fact that its atmosphere is always an oxidising one. Part of the S escapes as  $\text{SO}_2$ , and carries away some heat; but this, according to Austin, is small compared to that lost by the CO and  $\text{CO}_2$  in the ordinary (C) process of *matte*-making.

Pyrites ( $\text{FeS}_2$ ) loses an atom of S at a dull red heat ( $700^\circ$ ), so that only FeS is present in the zone of fusion, and Austin considers that the theoretically maximum temperature, T, attained, at or near the tuyères, when the theoretical quantity of blast acts upon the charge, is shown by the expression—

$$T = \frac{\Sigma ag + atq}{\Sigma pc - C}$$

where  $a$  = heat of combustion of each element (Fe and S);  $g$ , their weights;  $atq$ , heat introduced by the blast, of weight  $q$ , at temperature  $t$ ;  $\Sigma pc$ , the sum of the products of the specific heats of the products of combustion by the corresponding weights (FeO,  $\text{SO}_2$ , N); and C, specific heat of FeS.

Taking the temperature of the blast at  $400^\circ$ , Austin finds  $T = 3,553^\circ$ . Of the total heat, 11 per cent. is contributed by the blast.

It is considered that the co-efficients employed by Austin are somewhat high, but yet, seeing that the internal temperature of the furnace ought not to exceed  $1,500^\circ$ , there remains a large balance of heat; one certainly sufficient to heat the silica and to fuse both slag and *matte*. The comparative utilisations of the heat may be estimated by contrasting the total calories evolved by the combustible in question with those remaining in hand after allowing for the raising to  $1,500^\circ$ , of the volatile products of combustion.

Taking  $\text{FeS} + 3\text{O} = \text{FeO} + \text{SO}_2$  ( $34.5 + 34.6 - 11.9$ ) = 57.2 calories or 1,298 calories per 1 kilo. of FeS are evolved: the heat introduced by the blast being deducted. Hence, for heating the slag (FeO,  $\text{SiO}_2$ ) and the *matte*, there remains—

$$1,298 - 1,500 [0.7272 \times 0.1553 + 1.82(\text{N}) \times 0.2438] = 164 \text{ calories} = \frac{164}{1,298} \text{ or } 12.6 \text{ per cent. of the total heat involved, or, including the heat (11.9 calories) introduced by the hot blast, 16 per cent.}$$

Taking now the case of carbon. In burning to  $\text{CO}_2$ , 3,600 calories are available, and to CO, —69 calories; so that, supposing that at the tuyères in a lead or copper smelting furnace, 45 per cent. burns to  $\text{CO}_2$ , and 55 per cent. to CO, there would be available,  $0.45 \times 3,600 = 0.55 \times 69 = 1,852$  calories, or a little less than 20 per cent. of the calorific value of the carbon involved.

Greater possibilities are therefore shown by the pyrites furnace.

The advantages of the Austin process may be summarised as follows:—

1. A means of melting very refractory mineral without the necessity of using *matte*s containing either lead or copper; iron pyrites serving both as melt and fuel.
2. Saving cost of preliminary roasting.
3. Saving cost of transit of fuel.
4. Utilisation of deposits, unworkable otherwise.
5. The greater heat at disposal allows of use of more siliceous slags; hence diminution in the weight of the charge and saving of labour.

The principal disadvantage is the necessity of employing fuel to heat the blast, and this fuel is additional to that which will be consumed in blowing, if there is no waterfall available. Austin estimates the consumption of fuel for this purpose at 5 tons for the air necessary to melt 1,000 tons—a very trifling matter.

The process undoubtedly possesses the greatest interest, and appears to have before it a brilliant future. Its field would be still further enlarged if the escaping sulphurous gases were utilised.—E. R. B.

*The Interaction of Sulphide with Sulphate and Oxide of Lead.* J. B. Hannay. Proc. Chem. Soc. 1894, 151. (This Journal, 1894, 639.)

In this paper the author examines the equations suggested by Percy to account for the smelting of lead in the reverberatory furnace. The two main reactions which are supposed to occur are usually represented by the equations  $\text{PbS} + \text{PbSO}_4 = 2\text{Pb} + 2\text{SO}_2$ , and  $\text{PbS} + 2\text{PbO} = 3\text{Pb} + \text{SO}_2$ ; and although Percy relies on the first as representing what

takes place, he also says that a mixture of the sulphate and oxide reduces the sulphide. The author finds that a much more complex reaction takes place, since metallic lead, when formed, attacks the remaining sulphate, producing litharge, which in its turn reacts with the sulphide, while some of the sulphide is removed by being dissolved in the metallic lead, and some is volatilised as the volatile compound  $PbS_2O_2$ . The result varies according to temperature and the method of mixing the substances. The following equations correspond with the results the author has obtained:—

(1.) Lead sulphide and sulphate mixed in molecular proportions and very finely ground, and brought to calm fusion:—

34.8 per cent. of lead was obtained instead of 76.3, as required by Percy's question. When the sulphide of lead is in small pieces the reaction yields more lead, but otherwise pursues a similar course:—

With excess of sulphate the result is:—

On fusing lead sulphide and adding solid sulphate, the result is:—

On fusing the sulphate and adding solid sulphide, the result is:—

The temperature in this last case was much higher owing to the high melting point of the lead sulphate, and thus a larger amount of fume was produced.

On mixing sulphate and oxide in the proportions which ought to form lead and sulphur dioxide, as by the equation:—

no such result was obtained, but the reduction took this form:—

The author has shown in another paper, that the sulphide and oxide do not react to form lead, but combine together to form the substance  $PbS.PbO$ , which is the basis of lead slags.

Professor Roberts-Austen said, in discussion, that Mr. Hannay's statements presented themselves under two main aspects. It might be well either (1) to test the accuracy of his views as to the action of atmospheric air on sulphide of lead, or (2) to endeavour to obtain evidence as to the existence of volatile gaseous compounds of sulphide of lead. The speaker had adopted the latter course. He stated that he had understood Mr. Hannay to say distinctly, that if a mixture of sulphide and sulphate of lead were heated strongly no reaction ensued; hence Prof. Austen's appeal in favour of the accuracy of certain of the equations which were given by Percy and accepted by metallurgists. He was glad, however, to find that Mr. Hannay did not maintain this extreme view. Prof. Austen had experimentally confirmed the fact that the following equation is

substantially correct. —  $PbS + 3PbSO_4 = 4PbO + 4SO_2$ . This is a very important point, as it is one of Percy's main equations; but he had pointed out on the previous occasion, that both this equation and the one which has hitherto represented the reaction between oxide and sulphide of lead are strongly endothermic, and in the case of an endothermic equation, some explanation had to be sought; energy in some form had to be imported into the system, and an endothermic equation would represent a reaction which would be less likely to take place at a low than at a high temperature. In the case of the well known endothermic interaction between carbon and the oxides of iron, it was probable that the iron carbonyl played an important part, which certainly pointed to the possibility of similar action on the part of *poisons metallic* compounds in the metallurgy of lead. The well-known statement, "that the volatilisation of sulphide of lead is promoted by currents of gas, such as proceed from the combustion of fuel," a statement made by Dr. Percy in 1870, might well be taken as a starting point. There could be no doubt that when galena is strongly heated in a porcelain tube between two plugs of asbestos in a current of sulphur dioxide, the galena is volatilised, and is driven right through the plugs, condensing on the other side of them. Such experiments were made in the School of Mines Laboratory, the temperature being carefully measured by the aid of a thermocouple, and it was found that at a temperature of 1,357° C., 9 grms. of galena lost 38.2 per cent. of its weight in sulphur dioxide in 20'; while 9 grms. of galena lost 37.7 per cent. in nitrogen in 20'. At a still higher temperature, 1,434° C., 9 grms. of galena lost 50.2 per cent. of its weight in sulphur dioxide in 20'; while 9 grms. of galena lost 72.3 per cent. of its weight in nitrogen in 20'. This result, showing the volatility of galena in ordinarily pure nitrogen, was not a little surprising; but Mr. Rose had made a perfectly independent experiment, the result of which quite confirmed the volatility of galena in nitrogen. Prof. Austen had also ascertained the fact that at 1,200° galena may be rapidly distilled *in vacuo*, and, so far, he had been unable to obtain any evidence in favour of the view that sulphur dioxide promotes the volatilisation of lead sulphide more than nitrogen does. He had, however, tried a further experiment. A kind of air thermometer was arranged, with a porcelain tube for a bulb, in which a certain amount of galena was placed in an atmosphere of sulphur dioxide. The tube was then heated strongly, and the expansion of the gas carefully measured by means of a moving index of mercury in a horizontal capillary tube. The presence of galena produced no abnormal change in the volume of sulphur dioxide such as might be expected to occur if a gaseous compound of sulphur dioxide and galena were formed. It should be remarked, however, that sulphur dioxide alone appears to exhibit contraction about 1,000°, and the cause of this fact is being examined; but the presence of galena did not increase the observed condensation. Metallurgists would welcome the proof of the existence of gaseous compounds of lead sulphide; but although Mr. Hannay had undoubtedly shown that the whole metallurgy of lead should be further investigated, the existence, composition, and nature of the volatile compounds could not, as yet, be considered to be established.

Mr. Rose had tried to isolate the supposed compound  $PbS_2O_2$  by means of Deville's hot and cold tubes, galena being heated to about 1,250° in a stream of sulphur dioxide, but had been unsuccessful, the sublimate on the cold tube consisting entirely of lead sulphide. It was to be remembered that several substances, such as ozone and oxide of silver, which, although more or less unstable at moderate temperatures, could exist at a white heat, had been prepared in this way, and the method had appeared to be the most likely one to succeed in effecting the isolation of  $PbS_2O_2$ . The failure was therefore not without significance.

Mr. H. C. Jenkins said that lead sulphide (galena) was easily volatile in a vacuum at a temperature only a few degrees above its melting-point. In a current of sulphur dioxide the rate of volatilisation was, as would be expected, much increased, but a similar current of nitrogen gave even better results than sulphur dioxide. Very careful experi-

ments were made with mixtures of galena and sulphate of lead, but, although some of the products resembled those that Mr. Hannay had described, yet the evidence obtained did not point to the existence of a volatile compound  $PbS \cdot O_2$ . In some cases only the acting compounds were present; in others the experiments were performed in an atmosphere of sulphur dioxide in the presence of furnace gas. Metallic lead was only seen as a separate product in the latter case. But it was found that pure metallic lead is capable of decomposing sulphur dioxide, forming sulphur and oxide. Experiments were still in progress with a view to obtain quantitative knowledge of the change. The existence of volatile lead compounds would, if proved, offer an easy explanation of the cause of lead fume, but in view of the volatile character of well-known compounds of lead at furnace temperatures, much more experimental evidence than has yet been afforded is needed to demonstrate the formation of new compounds.

Dr. Armstrong said the experiments which he had witnessed certainly favoured the conclusion that sulphur dioxide exercised a specific effect in volatilising lead sulphide; but assuming that the evidence that combination took place was satisfactory, he could not regard Mr. Hannay's observations on the extent to which volatilisation took place as satisfactory determinations of the composition of the volatile compound; such a compound would probably be dissociable, and, if so, it was not to be expected that the gas and galena would pass over and be collected in exact molecular ratios. The strongest evidence was undoubtedly that derived from passing air into molten galena; the manner in which galena volatilised and passed away as lead sulphate under such conditions was extraordinary, and still more remarkable was the fact that, as Mr. Hannay stated, just half the lead was obtained in the metallic state. Experiments made in his laboratory under Mr. Hannay's direction had given this result, and it was certainly a remarkably coincidence if the result were but accidental. It appeared to him that, although Mr. Hannay could not be held to have established his point, he had called attention to peculiarities in the behaviour of lead sulphide which were of great interest to metallurgists, and that he had clearly made out a case for inquiry.

Mr. Hannay, in reply, said that he was glad to find it was now recognised that the simple equations of the textbooks did not adequately represent the facts, and that nearly all the furnace reactions of lead compounds were very complex. As to the volatility of the sulphide and the formation of a definite compound with sulphur dioxide, this conclusion was based on the action of air on molten galena, an action which always proceeded in the same manner, and was represented by the equation  $2PbS + O_2 = Pb + PbS \cdot SO_2$ , as exactly one-half of the galena is reduced to lead and left in the metallic state, and one-half is volatilised with the sulphur dioxide. Whether this was a definite compound or a mere chance volatility in molecular proportions was a question which might still admit of experimental investigation, and it was to be hoped that some of those who had spoken would carry the work further. As showing that sulphur dioxide when set free in intimate contact with molten galena, does act in a special manner, it might be stated that while nitrogen and hydrogen gases passed at the rate of 1 litre in three minutes through the molten sulphide, carried over the galena as vapour at the rate of 3.5 grms. per litre of gas passed, air under the same conditions carried over 5.2 grms. per litre. Now if the amount carried over by the nitrogen of the air were the same as that carried over by pure nitrogen, there is a large excess carried over by the sulphur dioxide (formed by the combination of the oxygen of the air with the sulphur of the galena), and this excess is present in nearly the proportion indicated by the formula  $PbS \cdot SO_2$  or  $PbS \cdot O_2$ . All the evidence pointed to the fact that when sulphur dioxide was formed in intimate contact with molten galena, every molecule of sulphur dioxide rendered volatile one molecule of galena, and subsequently deposited it on cooling. The volatility is so profoundly modified by temperature, that experiments are not comparable unless carried out at the same temperature, a result difficult to obtain; but Mr. Hannay hoped that Prof. Roberts-Austen would test the

matter and lay down accurate data for future work, as all statements of temperature had hitherto been only the roughest approximations.

#### *Hempel's Experiments on Zinc Smelting in Blast Furnaces.* Bull. Soc. Chim. 1894, 12, 248—252.

THE reduction of the zinc oxide in a blast furnace is quite possible if access of air be prevented, either by using steam or an excess of carbonic acid. The results achieved in the lead furnaces employed in the Harz district prove this assertion. On account, however, of the volatility of zinc, the furnace gases carry away large quantities of this metal, and in order to avoid enormous losses, it becomes necessary to precipitate it from the gases. The usual means for this purpose are insufficient in this case, but the problem has been solved by submitting the gas to centrifugal action, when the volatilised metal is obtained in the form of bead-like granules at a temperature of about 500° C. The experiments were carried out with a mixture of 1 part of oxide of zinc, 0.65 part of limestone, and 3 parts of coal. This mixture, heated in a crucible, gave a coke-like mass, containing about 22.7 per cent. of zinc and 49.7 per cent. of carbon. This product was treated in a small furnace working with a cold blast and provided with a Parry's hopper for feeding in the charge. The furnace gases were passed through a centrifugal ventilator, making 1,500 revolutions per minute, and then travelled through a vertical condensing flue. The pyrometer indicated a temperature for the gas of 470° C., and a content of 4 per cent. of carbonic acid was found. After some hours working only little zinc dust was found near the ventilator, more being found on the top of the condensing flue. Most had been carried away. This small quantity of zinc found near the ventilator proves that the condensation of the metallic vapour can only be carried out successfully at temperatures below 470° C. Experiments made by passing currents of different gases at varying speeds over the surface of zinc at a white heat demonstrates the fact that the formation of zinc dust depends upon the dilution of the metallic vapours as much as upon the chemical nature of the diluent gases. These experiments further showed that the zinc is volatile at a temperature very little above its melting point, i.e., about 500° below its boiling point. This explains why zinc smelting in a blast furnace where the fused metal is necessarily in contact with considerable volumes of gases, leads to the formation of zinc dust. The condensation of volatilised substance results in the formation of solid masses or coherent liquids, only if the dilution of the volatilised substance by indifferent gases, does not exceed a certain limit. Contrary to general opinion the reduction of the oxide of zinc takes place much below the boiling point of the metal. These facts suggested an attempt to manufacture very dense zinc-grey by the use of a polygonal screen or jacket against which the condensed metallic dust would be thrown. 17.5 kilos. of the above-mentioned coke-zinc were used. Between furnace and ventilator 1,010 grms. of zinc dust containing 72 per cent. of zinc were deposited; from the ventilator 2,370 grms. containing 90 per cent. of zinc were obtained; in a bag behind the ventilator 458 grms. containing 82 per cent. of zinc were collected. The escaping gases were free from zinc, and contained from 1.8 to 4 per cent. of carbonic acid. The rest of the zinc not accounted for above was absorbed by the lining of the furnace. This shows that it is possible to manufacture zinc-grey of high density in a blast furnace and to collect it by means of a ventilator. An interesting experiment was made by adding to the coke-zinc an argentiferous lead ore and ferric oxide. The latter is either reduced or scorified. All the lead and silver distil with the zinc. From ores rich in lead and silver, these metals can therefore be obtained partly in the metallic state, partly in the form of dust, and, if a satisfactory method for the treatment of this dust can be found, it is evident that the whole process would become of considerable practical importance. For the partial separation of these metals distillation was tried. The distillation of the dust, however, offering great practical difficulties, it was submitted to a pressure of 100 atmospheres, whereby it was obtained in the form of solid blocks, the volume of which is about one-tenth that of the original dust. On distilling the

blocks without addition of carbon very pure zinc to the extent of two-thirds of their weight was obtained. The residue contained  $\text{SiO}_2$ , 11.6;  $\text{Fe}_2\text{O}_3$ , 2.9;  $\text{CaO}$ , 0.6;  $\text{Zn}$ , 33.6;  $\text{S}$ , 8.1;  $\text{PbS}$  +  $\text{Ag}_2\text{S}$ , 1.05.

This residue, if the proportion of silver present be sufficient, can be very satisfactorily treated by the usual processes. The distillation of the compressed dust is preferable to the distillation of zinc oxide with carbon, as there is evolution of no gas, and therefore no loss of metal from this source. There is also a saving of space and fuel, owing to the conductivity of the compressed metal being much greater than that of the dust. From the above it follows that the treatment of zinc ores in blast furnaces requires three operations: (1) manufacture of zinc dust, deposited by centrifugal force; (2) compression of the zinc dust; (3) refining of the zinc dust by distillation. The ores, sulphides, or carbonates must be well roasted. Ferruginous ores should be reduced as much as possible with a reducing flame. Calcined fluxes would have to be used which, together with bituminous coal, are mixed with the ore and coked in an Appolt furnace, from which the red-hot coked mixture is at once transferred to the blast furnace. The gases, cooled to  $50^\circ\text{C}$ ., pass subsequently through one or more centrifugal ventilators provided with polygonal jackets. No more than 4 per cent. of carbonic acid should be contained in the gases. The distillation is carried out in crucibles of slightly greater diameter than that of the cylindrical blocks of compressed dust.—C. O. W.

*On New Alloys of Copper (Ducta Metal).* G. v. Knorre. *Zeits. angew. Chem.* 1894, 238.

THE specific gravity of this metal is 8.077 at  $16^\circ\text{C}$ ., its tensile strength 58 k. per sq. mm., its coefficient of elasticity 48 k. per sq. mm., its elongation under tensile strain 14 per cent. in 100 mm. of original length. The analysis of this alloy gave the following figures:—

	I.	II.	III.	IV.	V.	Mean.
Tin and antimony ..	2.25	2.21	2.20	..	..	2.22
Iron .....	1.70	..	..	1.73	..	1.71
Aluminium .....	1.72	1.69	..	..	..	1.70
Copper .....	64.79	64.80	64.80	64.72	64.77	64.78
Zinc .....	29.49	..	29.51	..	..	29.50

According to the statement of the makers, cadmium is an essential component of this alloy, but analysis showed it to be free from this metal. On the other hand the makers do not mention the presence of aluminium in the alloy.

The analysis of a tube gave the following figures:—

	I.	II.	Mean.
Copper .....	61.42	61.50	61.46
Lead .....	0.85	0.87	0.86
Iron .....	0.92	0.90	0.91
Manganese .....	0.78	0.74	0.76
Zinc .....	35.98	..	35.98

showing that it consisted of an alloy of brass and lead, to which, on melting, ferro-manganese had been added as a reducing agent.—C. O. W.

#### PATENTS.

*Separating and Purifying Metals.* J. A. Mays, Hampstead. Eng. Pat. 8964, May 4, 1893.

THE claim is limited to the separation of metals from molten lead by the use of molten zinc or an alloy of zinc. The molten lead containing gold, silver, or other substances

to be separated is made to pass in minute particles through the molten zinc or zinc alloy, when the lead is purified, and the gold, &c., are retained by the zinc. The reactions may be effected either by the aid of gravity or by that of centrifugal force.—J. H. C.

*Improvements in the Manufacture of Metallic Alloys or Compounds.* R. Howarth, Wolverhampton. Eng. Pat. 15,117, Aug. 8, 1893.

FOR the purpose of thoroughly alloying iron, copper, tungsten, or other metals with zinc, without loss of the latter metal, the mixture is heated to and maintained at a red heat in a flanged crucible, which is capped with an iron collar, so arranged that by means of a collar a lid may be firmly pressed into contact with the crucible. The cover is luted on, and the crucible, which should be nearly filled, is made of plumbago. The time required for heating must be determined by experiment. When the alloy is required for further mixture the metal may be allowed to solidify in the pot, and may be subsequently broken up.—W. G. M.

*Improvements in Processes of Coating Metals with Aluminium or its Diluent Alloys.* E. C. Broadwell, Philadelphia. Eng. Pat. 15,152, August 8, 1893.

THE metals to be coated are first cleaned, then covered with a flux containing some halogen compound of an electro-negative metal, such as tin chloride, and then dipped in a bath of molten aluminium or alloy.—J. H. C.

*Improvements in Apparatus for the Manufacture of Cast Iron and Steel.* C. Allen and C. Davy, Sheffield. Eng. Pat. 15,875, August 22, 1893.

A STORING and mixing vessel for liquid metal is described, the cross section of which is rather more than a half-circle; it is provided above with a covered movable channel, which can be detached when not in use, for the feeding of the metal into the mixer from ladles brought alongside, and at one side is a tap-hole which may be brought into use by tilting the vessel and opening a protected plug. The whole vessel is mounted on rollers and fitted with hydraulic machinery adapted to communicating transverse oscillating motion to it, while along the centre of the bottom is a longitudinal ridge to aid in the mixture of the fluid contents. At either end are detachable flues, placed in the axis of oscillation, and connected with regenerators, which serve to maintain the fluidity of the contained metal when necessary.—W. G. M.

*A Process for Precipitating Precious Metals from Solutions.* C. Moldenhauer, Frankfort-on-Maine. Eng. Pat. 16,361, September 2, 1893.

ALUMINIUM is employed instead of zinc, and in the presence of free alkali or earthy alkali, for precipitating gold from a cyanide solution. This results in an important economy of cyanide of potassium which is continually being regenerated as shown by the following equations:—

—J. H. C.

*Improvements in the Method of Separating Metals from Ores and from other Mixtures of Insoluble Substances therewith.* E. R. Besenfelder, Grosse Mochbern, Silesia. Eng. Pat. 23,619, December 8, 1893.

THE dry ores are exposed to heat under pressure in contact with ammonium chloride or a similar salt. Any excess of reagent and the volatile products are distilled or sublimed and condensed in a suitable receiver and subsequently

utilised. The fixed residue is heated with a solvent such as water and the solution as well as the insoluble portion are subsequently dealt with. The heat and pressure may vary within considerable limits, thus, in treating the strontian residues from the de-saccharisation of molasses one part of the dried and pulverised residue is mixed with two parts of ammonium chloride, placed in a suitable rotating vessel and heated for one hour to 350° C. under a pressure of from 3 to 6 atmospheres. The volatile, soluble, and insoluble parts obtained as above are then separately treated and purified by known means.—J. H. C.

*An Improved Apparatus for Precipitating Gold and Silver from Cyanide Solutions.* A. H. Bell and C. Carter, Ithaca, Utah. Eng. Pat. 1472, January 23, 1894.

The solution is made to rise up against and between moveable and stationary zinc surfaces which are kept bright by friction against each other. The particles of zinc so removed, pass into the solution together with the precipitated gold and silver which are collected in a settling chamber and taken out at suitable intervals.—J. H. C.

*Improvements in Furnace and Apparatus for Working Gold, Silver, Copper, and other Ores.* C. A. Allison, London. From J. J. Storer, F. Martin, and G. O. Eaton, Helena, U.S.A. Eng. Pat. 6263, March 28, 1894.

In this specification, a vertical shaft with an inner lining has at its summit a series of fire-places with charging doors and with fire bridges leading into a central chamber, through which the finely divided ore passes as it falls from an upper feeding channel down the main axis of the shaft. The ore, stayed for a moment by the resistance of the gaseous currents, has time to become ignited, and in falling through the shaft the oxidation may become complete. If it contain insufficient sulphur to supply the necessary additional heat for complete roasting, the ore may be mixed with carbonaceous material. The fire-places are provided with separate flues to carry away smoke at the time of lighting; these are then closed, and an artificial draught produced by a fan, draws down the shaft the products of combustion, with the ore which is afterwards added. At the bottom the roasted ore may fall into a trough of water running through zig-zag condensing chambers, along which it is conveyed by a revolving screw to the exit door. Or it may fall upon a dry hearth, the gases passing through a water-spray condensing chamber for the recovery of dust. Or it may be received upon the hearth of a reverberatory furnace, provided with a separate grate, so that the roasting and smelting are accomplished in the same furnace, the gas here also being passed through depositing chambers. In whatever way the ore is received, and the dust is primarily recovered from the gases, the latter pass from the depositing chambers through the exhaust fan, in which they are again thoroughly admixed with spray, produced by the action of the fan upon water introduced for the purpose, to an escape shaft, the lower part of which is filled with lattice or cob-work of wood for the interception of the last traces of finely divided material which would otherwise escape.—W. G. M.

*Improvements in Melting Furnaces.* F. X. Dantzenberg, jr., Crefeld, Königshof, Germany. Eng. Pat. 6983, April 7, 1894.

A VESSEL lined with fireclay is suspended from pivots, so that it may be tipped up on a horizontal axis. On one side is a blast chamber communicating through tuyère holes with the interior of the vessel, and on the opposite side is a tap-hole on the bottom, connecting by a bent channel in the fireclay walls with an outer tap-hole half way up the side of the containing-vessel. The material to be melted may be placed (with fluxes) in alternate layers in this crucible, and when melted is poured off from below, free from admixture with slag or dross. When the substance to be fused should not come in contact with fuel, it may be contained in an

inner liner with apertures beneath, through which the liquid mass may find its way to the tap-hole. The tapping is effected by tilting the whole vessel in such wise that the tap-hole is on the under side.—W. G. M.

*Process for Treating Blast Furnace Gases for the Extraction of Alkaline and Ammonium Compounds, Iodides, and Iodine therefrom.* From O. Imray, London. P. Gredt, Esch-sur-Alzette, Belgium. Eng. Pat. 10,589, May 31, 1894.

FURNACE gases are passed through pipes of about 3 yards diameter and 25 yards length, set in pairs in basins wherein either added or condensed water furnishes a water seal, this water being pumped up from time to time into a receiver constructed in the upper part of the pipes and provided with a perforated bottom, from which the liquid falls as a fine rain, carrying the dust with it, and soluble matters in solution. There is another connected set of pipes placed horizontally, through which the partially purified gases pass. The lye drawn off is evaporated in basins, "heated by the same purified gases," and when concentrated, "containing on average 0.75 per cent. of iodine," is run into an alembic suspended in a stove in which refractory bricks are set with open spaces forming channels, to which gas and air are admitted through a number of openings, "in order by their combustion to heat the bricks and alembic to a white heat." The vapours and gases formed, containing ammonium compounds and cyanides, are passed into sulphuric acid, and the gases which escape from the receiver are taken to a Glover tower, where hydrochloric acid and cyanides are recovered. The mass remaining in the alembic is dissolved in water, and the solution is fractionally crystallised to separate calcium chloride, potassium chloride, and potassium iodide, from which latter iodine is obtained by known processes.—E. S.

*Improvements in the Manufacture of Steel.* W. P. Thompson, Liverpool. From E. Bertraud and O. Thiel, Kladno, Bohemia. Eng. Pat. 10,923, June 5, 1894.

Two or more open-hearth furnaces are placed in cascade position on different levels. They may contain acid or basic linings, according to circumstances. In the uppermost furnace the silicon and some of the carbon are removed; the contents are next tapped into the middle furnace (being thus separated from the acid slag first produced) and here the metal is dephosphorised. It is lastly run, freed from the phosphoretic slag, into the lowest hearth to receive the recarbonising charge prior to tapping finally. Two furnaces on the same level may be used to treat different materials simultaneously, and the contents of the two mixed on the hearth of a third and lower one, for the addition of spiegel and ferro-manganese.—W. G. M.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*Electrical Heating by Induced Currents.* Zeits. f. Elektro-techn. u. Electrochem. 1894, 93.

A VESSEL of suitable heat-resisting, and preferably non-conducting, material is constructed with a deep indentation in the bottom. Into this indentation is inserted the single primary coil of a coreless transformer T. Within the vessel is a ring of lead, or, as in the figure, of carbon

fragments, which becomes heated by the induced currents flowing in them, when a suitable current is passed through

the primary coil. If the vessel be made of metal it will itself act as a secondary conductor, and no additional ring of lead or carbon will be needed.—W. G. M.

*The Aim of Electro-Chemical Investigations.* F. Oettel. *Zeits. f. Elektrotech. u. Electrochem.* 1894, 35—57.

RECALLING the fact that the simple application of Faraday's law can seldom be made, except when the period of electrolysis is very short, owing to secondary reactions, such as the formation of per-sulphuric acid in decomposing copper sulphate, or of that of acid and ozone in the water voltameter, or as the decomposition of nitric acid in the electrolysis of copper nitrate, the author urges that a new era will commence for electro-chemistry when electro-chemical reactions are studied with the aid of the ampère-meter and the balance, as a new epoch began for chemistry with the quantitative examination of chemical phenomena. Since physical conditions, such as concentration and temperature of solution, current density, and rest or motion of the electrolyte, have so great an influence on the reactions of the bath that they may sometimes be made oxidising, reducing, or neutral by a variation of these conditions, it is necessary to record complete details in describing a research if the full value of the work is to be assured. In studying electro-chemical reactions, the current should be measured, and from this the theoretical result of the operation should be calculated according to Faraday's law; if then by weighing or titration this result is reached, it may be concluded that no secondary reactions have occurred. But if there be a difference beyond the range of experimental error, and this difference is found to recur on repeating the experiment, a further examination must be made into the nature, conditions, and extent of the by-reaction. Such secondary reaction may result from electrolysis of new products formed, or by their chemical interaction. For technical purposes, the conditions yielding the highest return for current expenditure must be determined. For small installations a copper voltameter may be used, made by immersing weighed copper plates or concentric cylinders in a beaker containing a solution of 15 grms.  $\text{CuSO}_4 + 5$  grms. of concentrated  $\text{H}_2\text{SO}_4$  and 5 grms. of alcohol in 100 cc. of water, the liquid being agitated by a gentle stream of hydrogen. The current to be recorded by this voltameter may range from 0.06 to 2.0 amperes per sq. dm., the result being 1.181 grms. of copper deposited per ampère hour. For larger operations an ammeter should be employed.—W. G. M.

*A Problem in Electro-Chemical Economy.* A. W. *Zeits. f. Elektrotech. u. Electrochem.* 1894, 95—96.

THE perfecting of electro-chemical processes is likely to result in the transference of many manufactures to mountainous countries where water-power is available. The actual cost of 1 h.p. as produced by water and by steam-power is with difficulty determined with accuracy, owing to the uncertainty of many factors; but for large installations it is certainly greatly in favour of the water-power. Houston and Kennedy, allowing only 2½ per cent. for depreciation, arrive at a cost of 12 m. per h.p. per annum for uninterrupted work at the Niagara 120,000-h.p. installation. For steam plant of this

size a far larger sum would have to be written off for repairs and depreciation, and the cost would amount to from 20 to 30 times the sum named. But even such installations as would be demanded by chemical works could be run more cheaply by water than by steam. As a case in point, potassium chlorate has recently grown into an important product, owing to its use in the manufacture of safety lucifer matches. This salt was first made exclusively in England, then German manufacturers entered the field, and now about 600,000 kilos, out of the 1½—2 million kilos, required annually are made by the *Société d'Electrochimie* (of Paris) at their works in Vallorbes (Jura), where an absorption of 2,000 h.p. of water-power produces the body, by the electrolysis of potassium chloride, at a selling price of 115—120 marks per 100 kilos. An estimate of the cost of production shows that this must yield a handsome profit, and that therefore the price might be lowered to a degree which would exclude competition from German manufacturers. Meanwhile a larger installation with water-power equal to 6,500 h.p. has been made at Mansboe in Dalecarlia (Sweden); and here the promoters (*Superphosphat Aktien gesellschaft*) estimate the cost per h.p. at one-tenth of that required in England. The transference of this one small industry is of itself unimportant; but it behoves chemical manufacturers, in countries where water-power is not available, to watch the progress of electro-chemical methods, and to be prepared to meet the competition of countries in which inaccessibility and other disadvantages is far more than counterbalanced by the natural advantages of a high available water-pressure.—W. G. M.

*Electrolytic Copper Deposition in the Stolbury Lead Works.* E. Cohen. *Zeits. f. Elektrotech. u. Electrochem.* 1894, 50—55.

THE ore to be treated contained 7—8 per cent. Cu, 10 per cent. Pb, and 0.05 per cent. Ag; besides this, a matte was produced containing 15—20 per cent. Cu., 5 per cent. Pb., and 0.04 per cent. Ag. The Marchese process was first tried, in which the matte, cast into thin slabs and slowly cooled, served as anode in a bath of copper and ferrous sulphates, the ferric sulphate formed being afterwards reduced by causing it to attack fresh regulus (this *Journal*, 1885, 600). Two Siemens-Halske dynamos, of the type CF 17, gave a current of 430 amperes and 35 volts at 700—800 revolutions; the current-values per bath being 30 amperes per square metre, and 1 volt. In calculating the profit to be expected from the installation, the adverse effect of the large stock of copper locked up in the baths was considered to be far more than neutralised by the increased value of the pure copper deposited (*vide Trans. Inst. C.E., 82, 446*). At first the process worked satisfactorily, but in a few days the pressure requirements of the bath slowly increased (in one case, up to 5 volts), owing to the separation of sulphur on the anode preventing contact of the liquid with the next layer; next, the honeycombed anodes crumbled and, falling to the bottom of the baths, produced short circuits. Polarisation was at first combated, but without success, by intermittent working; then, as it was ascribed to the formation of  $\text{PbO}_2$ , the copper percentage in the anode was increased and that of the lead reduced; but neither this, nor an alteration of the iron percentage, was effectual. The deposited copper also contained traces of Sb, Bi, Pb, Fe, Zn, and S. Lead anodes were next substituted for matte, using the same electrolyte, which lasted longer, owing to the non-extraction of iron from the anodes, but polarisation was produced by the peroxidation of the lead, so that the initial voltage of 1.7 had to be raised to 2.15, while only 60 per cent. of the theoretical yield of copper was obtained. To prevent this peroxidation, sulphur dioxide, formed by burning sulphur, was blown with air into the bath. The resistance was unaffected, but the yield of copper was increased, and the metal was of high quality (99.984 per cent. Cu). One objection to this process was the excessive quantity of sulphuric acid formed, which dissolved too large a proportion of the anode, and caused crystallisation to take place in the vats. The products of roasting copper sulphide ores was too dilute, but before

erecting muffle-furnaces to obtain a more concentrated sulphur dioxide gas, the Siemens-Halske process was brought out, and received a trial.

The installation of this process (see this Journal, 1892, 534) was entrusted to Dr. Höpfner in 1888. Carbon anodes were used, and the anodes were in separate compartments with parchment-paper walls, so that the anode and cathode liquids were kept distinct. Thus, while copper was deposited on the cathode, the ferrous salts in the solution were peroxidised at the anode by the  $\text{SO}_4$  liberated; so, when the copper had been deposited from the cathode liquor, this was transferred to the anode cells, where the iron was peroxidised. It was next passed over copper matte, where it acted as follows:—

and was then available for the cathode compartments. The regeneration was effected either by mixing the ore and liquid in rotating vessels, and allowing the fine deposit to settle before use, or by running the liquid over the ore in vats with several superposed false bottoms. The baths first employed were lead-lined wooden vessels, 2·2 m.  $\times$  1 m.  $\times$  1 m., and had each 15 anodes consisting of rows of carbon rods 1 cm. thick and 45 cm. long, and 16 cathodes (80 cm.  $\times$  80 cm.  $\times$  1 mm.).

At Höpfner's recommendation, the anodes were joined up, by passing the ends, to the distance of 3 or 4 cm., through holes in a perforated copper strip, and then coating the projecting ends and the strip with copper electrolytically. The vats were placed terrace-wise, and the cathode liquid circulated from end to end, the anode liquids being transferred through the series with the aid of glass siphons regulated by screw clips. Air was blown into the anode cells, to equalise the oxidising action of the current. The siphons were not found to act well, any failure on their part causing an overflow from the anode to the cathode cell. The parchment became swollen and very tender after a few days' use, and the carbons simultaneously became very fragile, so that at the slightest provocation they crumbled, and the accumulated fragments at the bottom of the cell broke the parchment membranes. Thus resistance increased, and in nine days the voltage required rose from 0·98 to 1·75. At this time Siemens and Halske had introduced a new bath (see Höpfner's patent, this Journal, 1891, 839), in which 16 cells, separated by parchment paper supported by a wooden frame, contained alternately anodes and cathodes. Side channels permitted communication between like cells, so that the two circulations could be kept up. Air was blown into the anode compartments, and the anodes were carbon rods, as before. The result of a three-months' trial showed no improvement in working; but when a membrane was broken, the whole apparatus had to be taken to pieces, in order to replace it; while the rupture of membranes and crumbling of carbons frequently required this to be done. Possibly the breaking of the carbon may be due to the use of a voltage of 1·8 where only 1 volt was recommended, owing to the evolution of gas within the pores of the carbon. The Stolberg Company have now finished experimenting in this direction.—W. G. M.

*Electric Heating.* Zeits. f. Elektrotech. u. Elektrochem. 1894, 8—10.

See under II., page 789.

*On the Efficiency of Heating by Electricity as compared with Heating by Combustion.* A. Wilke. Zeits. für Elektrotech. u. Elektrochem. 1894, 2.

See under II., page 790.

## PATENTS.

*Improvements in Secondary Electric Batteries.* The Lithanode and General Electric Company, Limited, and J. T. Niblet, both of London. Eng. Pat. 13,217, July 6, 1893.

THE invention relates especially to "solid secondary electric batteries," such as that described in Eng. Pat. 14,411 of 1890 (this Journal, 1891, 839). In this case, lithanode materials are placed in the spaces for active material, and the formation of lithanode proceeded with. Crystals of magnesium sulphate may be added, and afterwards dissolved out, so as to leave pores or interstices.

Or the cell may be constructed with alternating electrodes of spongy lead and lithanode with diaphragms or separators between of porous clay or asbestos, or of inert perforated material.—E. T.

*Improvements in or connected with Apparatus for the Manufacture of Chlorate of Potash by Electrolysis.* F. Hurter, Liverpool. Eng. Pat. 15,396, August 12, 1893.

See under VII., page 810.

*Improvements in Apparatus for the Electrolytical Decomposition of Brine and other Liquids.* F. G. Baily and M. Guthrie, Liverpool. Eng. Pat. 15,610, August 17, 1893.

THE apparatus is designed to prevent the mingling of the substances formed at the two electrodes by the supply of fresh electrolyte and the removal of the decomposed or modified liquid. The electrolyte is fed into the cell continuously at points lying between the electrodes, and overflows are arranged near to or behind them. To assist in preventing the admixture of the products formed at the electrodes, the electrolyte around each is confined by a porous or perforated screen, through which the electrolyte flows from the centre towards the electrodes, the rate of flow being such as to prevent diffusion.—J. H. C.

*Improvements in the methods of effecting the Electrolysis of Saline Solutions.* L. A. P. and H. E. A. Liéard, Paris. Eng. Pat. 6046, September 22, 1893. (Under International Convention.)

THE electrodes are placed horizontally, the anode uppermost, a porous partition being placed between them. This partition is of peculiar construction, and specially devised so as to afford the greatest possible obstacle to re-combination and solidification, and, at the same time, the greatest possible electric conductivity.—J. H. C.

*Improvements in Primary Galvanic Batteries, and in the Liquids used therein.* W. H. Longsdorf, London.—From G. Hewitt, New York, U.S.A. Eng. Pat. 3674, February 20, 1894.

A DOUBLE fluid-cell, in which the central electrode consists of several carbon plates clamped together at the top by an aluminium bolt and nut, and furnished with a binding screw. The bolt passes also through separating pieces of aluminium sheet, which cause the immersed part of each carbon plate to be separated from its neighbours by about  $\frac{1}{16}$  in. The depolarising solution is made as follows:—Seven parts of sulphuric acid are added to eight of a saturated solution of crude sodium nitrate. The crystals of sodium sulphate formed are removed, and to the liquid remaining one-seventh part of water is added. In the zinc or zinc cell the sodium sulphate separated as already described may be used, or in its place common salt. In either case a small quantity of bisulphate of mercury is added, and, if found better, a little sulphuric acid.—E. T.

*Improvements in or in Connection with Apparatus for the Electro-Deposition of Metals.* H. Alexander, Berlin. Eng. Pat. 8917, May 1th, 1894.

The poles of the battery are arranged so as to allow the articles to be treated, to rest directly upon the cathode, or on a wire netting supported directly by it, instead of being suspended from it by separate wires as is usually done. The points of contact are changed by shifting or turning as may be required. The arrangement can be readily carried out in the form of stages at different levels in deep baths.

—J. H. C.

*Method of Bleaching Paper Pulp or other Flocky Substances.* J. W. Abom, Stockholm. Eng. Pat. 8964, May 5, 1894.

See under XIX., page 834.

*Improvements in Electrolytic Apparatus.* T. Craney, Bay, U.S.A. Eng. Pat. 9761, May 18, 1894.

A LONG tank constructed preferably of boiler-plate, is divided by a longitudinal partition into two compartments communicating at the ends. A screw is provided to insure continual circulation of the liquor. In each compartment is a row of cylindrical vessels perforated through all but the upper portion, the perforated part being over-wound with asbestos sheet to form a porous diaphragm; and that again with a "wire screen" to act as cathode. Inside this vessel is a second one of much smaller diameter, also perforated, and containing carbon to act as anode. The outer cell is closed in round the anode, and provided with an inlet pipe reaching nearly to the bottom, and an outlet pipe projecting from the imperforated portion, and passing through a stuffing box in the wall of the tank to communicate with a drain pipe outside. This outlet-pipe serves both to carry away any overflow, and to lead away the gases formed. The whole is carried on an iron cage, and is easily removable. The action is continuous, any cell becoming faulty can be removed without disturbing the rest, and be replaced by a good one. The apparatus is designed more especially for the electrolysis of common salt.—E. T.

*Improvements in Electrolytic Apparatus.* F. Craney, Bay, U.S.A. Eng. Pat. 9949, May 22, 1894.

THIS apparatus also is for the electrolysis, more especially of common salt. The outer vessel is a long shallow tank constructed preferably of boiler-plate. Into this dips a dish or tray of iron wire, the middle portion being most deeply immersed, and the sides sloping gradually upwards till they are above the surface of the liquid. This is supported from the sides of the tank by numerous suitably shaped iron bars and is covered by a layer of sand, cotton, fibrous asbestos or other material, which, while very suitable for use as a porous diaphragm, requires mechanical support. An earthenware cover fitting over the dish, converts the latter into a closed second compartment. A layer of carbon granules over the porous material forms the anode, and makes electrical connection with the dynamo by numerous earthenware tubes, forming part of the cover, which contain gas carbon electrodes. Gases are drawn from the anode compartment by means of a fan, and arrangements are made for keeping up a continuous circulation of the liquid. The iron wire tray forms the cathode.—E. T.

*Improvements in Plates for Secondary Electric Batteries.* Georges René Blot, Paris, France. Eng. Pat. 10,169, May 25, 1894.

AN improved construction of accumulator batteries of the Planté type, wherein two narrow ribbons of lead, transformed in advance, are wound together lengthwise on a stout strip of antimonial lead, of the same width as core. Both ribbons are of embossed or grooved lead, and one in addition is furnished with corrugations to allow free penetration of the electrolyte. A number of these flat bobbins

are mounted in a lead frame to form a plate, the bobbins being slightly apart to allow of swelling, and the electrical attachment being made by lugs on the core, which are burned on to the frame.

In another construction a number of strips of "transformed" lead are laid together and a supporting frame made by casting lead round them. The strips may in this case be alternately grooved "transformed" lead, and smooth hard antimonial lead, which latter will lead the current into the active material when all the lead of the first set has been practically eaten through.—E. T.

*Improvements in Electrical Accumulators or Storage Batteries.* J. Y. Johnson, London. From La Société, "L'Accumulateur Fulmen," Paris, France. Eng. Pat. 10,853, June 4, 1894.

To prevent the cases or sheaths of perforated celluloid, or such material, as that in which accumulator plates are sometimes enclosed, from swelling and bulging out at the sides, these latter are at places connected by strips or blocks of celluloid, passing through the electrode and cemented to them. In some cases small split keys are put through case and electrode, and their projecting ends expanded or separated, so as to hold the sides of the case in, and prevent their bulging.—E. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*Pea-Nuts and Pea-Nut Oil.* U.S. Consular Reports, July 1894, Vol. 45 [166] 378—389.

A REPORT on pea-nuts and pea-nut oil, as regards occurrence, modes of extraction, exports, prices and methods of production, and utilisation of residues and refuse, in the following countries:—Algiers, Bordeaux, Marseilles, India, Mozambique, and Senegal. (This Journal, 1894, 530—531.)—W. S.

*Pea-Nut Oil.* U.S. Consular Reports, through "Chemist and Druggist," August 18, 1894.

THE report of the American Consul at Marseilles contains some further facts concerning the manufacture of pea-nut oil, an oil which is largely coming into use for various economic purposes (see also this Journal, 1894, 530). Extraction of oil from pea-nuts is rapidly increasing, no fewer than 17 factories being at present engaged in the industry, and the quantity of nuts imported at Marseilles for this purpose during 1893 exceeding by 314,000 metric quintals (69,224,400 lb.) the importation for 1892. The general method of producing the oil is as follows:—On arriving at the factory the pea-nuts are first placed in a machine of the nature of a "winnowing," in which all outside dirt and other foreign substances are removed. Having been thus superficially cleansed, the nuts are conveyed by an Archimedes screw to the shelling-machine, where they are deprived of the shells. Thence the nuts fall into the first triturating-machine, consisting of a pair of cast-iron rollers, where they are coarsely ground, and at the same time any foreign bodies, stones, &c., are by an ingenious arrangement rejected. From this machine the meal passes to another, where it is again ground finer, and thence into a long hexagonal case forming a sieve, through which the fine meal passes, while the coarse is sent back to the rollers again. The meal is then pressed in "scourtins" made of horsehair, a pressure of 2,850 lb. to the square inch being exerted and left on for an hour, which is sufficient to extract all that can be obtained in the first yield. The meal is then removed from the "scourtins," ground a second time, heated to a temperature of about 70° C.

(158 lb.), and a second pressing is effected. If oil of a very fine quality is required the nuts are crushed only once, partially-ground nuts yielding a smaller but finer product. The yield varies according to the quality of the nuts. Mozambique nuts produce about 50 per cent. in the first pressing, and the value is from 70 f. to 95 f. per 100 kilos.; the second pressing yields about 12 per cent., the value of which is from 45 f. to 50 f. per 100 kilos.

The oil is largely devoted to the manufacture of white soap, for which it is highly prized. It is also used as salad oil and in the composition of margarin. Large quantities are also sold as olive oil, principally in the United States. A smaller amount is used for illuminating purposes. The cake left after pressing is particularly rich in nitrogen and forms an excellent cattle food, and commands a price of 13 f. per 100 kilos, if made from shelled nuts.

#### *The Constitution of Turkey-Red Oils.* P. Juillard.

Bull. Soc. Chim. 11, 1894, 280—286.

THE different products formed by the action of sulphuric acid on ricinoleic acid are as follows:—

1. *Ricinoleic sulphuric acid*,  $\text{OH} \cdot \text{SO}_2 \cdot \text{O} \cdot \text{C}_{17}\text{H}_{33}\text{CO}_2\text{H}$ , is a dibasic acid, stable only in dilute solution, concentrated solutions readily decomposing into sulphuric and ricinoleic acids. It has the characteristic property of forming acid salts when treated with solutions of almost any salt, e.g., on agitating its solution with potassium chloride, acid potassium "ricino-sulphate" and HCl result. The corresponding sodium salt was formerly erroneously described as diricinolein-sulphuric anhydride.

#### 2. *Dihydroxystearo sulphuric acid*—

almost always accompanies (1) and possesses similar properties

#### 3. *Dibasic diricinoleic acid*—

A thick liquid soluble in alcohol. Its methyl and ethyl salts, however, are almost insoluble in alcohol, and on this property is based a method of separation of this from other acids, particularly from isoricinoleic acid. It is very stable, and is not saponified by boiling alkalis.

#### 4. *Monobasic diricinoleic acid*—

This is the first member of the series of polyricinoleic acids having the general formula—

When castor oil is treated with sulphuric acid, in the proportions of one part acid (98 per cent.) to eight parts of castor oil, the product consists almost entirely of these polyricinoleic acids, while with a larger proportion of sulphuric acid, isoricinoleic and dibasic diricinoleic acids chiefly result.

5. *Dioxystearic acid*,  $\text{C}_{15}\text{H}_{26}\text{O}_4$ , is found in small quantity in crude isoricinoleic acid, it melts at  $66^\circ$ — $68^\circ\text{C}$ ., and is very soluble in alcohol and ether.

6. A solid acid which melts at  $70^\circ\text{C}$ ., and is soluble in alcohol and ether, answers to the formula  $\text{C}_{36}\text{H}_{70}\text{O}_7$ , and appears to be a molecular compound of dihydroxystearic and ricinoleic acid.

7. *Isoricinoleic acid*,  $\text{C}_{15}\text{H}_{34}\text{O}_5$ .—An oily liquid soluble in alcohol and ether. It is distinguished from ricinoleic acid by its solubility in petroleum ether; and appears to be a ketonic acid with formula—

or, perhaps—

Experiments made with the Turkey-red oils resulting from the action of sulphuric acid on oleic acid and olein, have shown that, starting from oleic acid, the first product is hydroxystearosulphuric acid  $\text{OH} \cdot \text{SO}_2 \cdot \text{OC}_{17}\text{H}_{33}\text{CO}_2\text{H}$ , from which is formed hydroxystearic acid  $\text{OH} \cdot \text{C}_{17}\text{H}_{33}\text{CO}_2\text{H}$ . In an analogous manner to ricinoleic acid, this acid condenses to form polyhydroxystearic acids.

Olein treated in the cold with sulphuric acid yields two acids, one mono-, the other dibasic, which appear to be addition products of sulphuric acid and olein. They are soluble in water, and readily form sodium and potassium salts.—R. B. B.

### PATENTS.

*Improvements in the Treatment of Cotton-Seed for the Removal of Fibrous Matters therefrom and in Apparatus therefor.* W. P. Thompson, Liverpool. From W. H. Stead, Geneva. Eng. Pat. 11,361, June 9, 1893.

THIS is described as an improvement on previous patents, 13,831, 1884 (this Journal, 1885, 585), and 10,992, 1887 (this Journal, 1888, 433). The improvement in the process is stated to consist in the treatment of the cotton-seed, for the removal of fibrous materials, with hydrochloric acid in a heated kettle, with constant stirring, adding oil or grease when desired, and separating the dust by friction and sieving with or without aspiration. The improvement in the apparatus consists in a stationary jacketed pan with revolving stirrer in combination with a sieving device. Also in a series of pans one below the other, having several stirrers and means for introducing acid at or near the top, and alkali or oil in the lower parts of the single pan or the lower portion of the series of pans, whereby the lint can first be destroyed by the acid and then the acid neutralised prior to its arrival at the sieving arrangement.—E. G. P. T.

*Improved Inspissated Oil for Electrical Insulating Purposes, and Method of producing same.* A. Geuttsch, Vienna, Austria. Eng. Pat. 16,597, September 4, 1893.

THIS is said to be a new article of manufacture, prepared by letting water containing salts in solution (such as carbonate of lime, carbonate of magnesia, magnesium hydroxide, sulphate of lime, oxide of iron) drip from a suitable height into the oil or fat, placed in a suitable boiler, and retained at a temperature of more than  $100^\circ\text{C}$ ., until the desired consistency is obtained for such inspissated or "concentrated" oil.—J. C. C.

*An Improved Process for Removing the Green Colour from Paraffin, Vaseline, and Lubricating Oils, which have had that Colour Imparted to them by Bodies containing Oxygen.* A. Wendtland, Berlin, Germany. Eng. Pat. 9179, May 9, 1894.

To illustrate the process, paraffin, vaseline, and lubricating oils, which have undergone a preliminary purification by

sulphuric acid, are taken as an example. These residues are coloured green. To remove the colour the mass is thoroughly mixed with soap solution in a finely-divided condition, in a manner described in detail. This soap solution is then separated by settling or by centrifugal force, and the purified products washed with hot water and a weak solution of barium chloride. The soap solution contains the colouring matter; the fatty acids, being separated by dilute mineral acid, may be used again. In connection with this treatment, a method of bleaching the paraffin or vaselines, &c., which have assumed a green colour through being treated with bone-black, is described, "by means of a treatment with methyl or ethyl alcohol, aldehydes, ketones, &c., either before or after the treatment with bone-black."

—J. C. C.

### XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

#### (A).—PIGMENTS, PAINTS.

##### PATENT.

*Improvements in the Manufacture of Plumbago or Graphite, commonly called Black-Lead.* P. F. Johnson, Liverpool. Eng. Pat. 10,424, May 29, 1894.

GRAPHITE crushed and passed through a sieve of from 120 to 150 meshes per inch, is stirred into a saturated solution of alum or aluminium sulphate at 212° F.; stearite is then added, and more water if required. After mixing, excess of water is evaporated until a consistency suited to grinding in a chilled steel or other mixer is obtained. More graphite may here be added; then, after thorough grinding, the material may be compressed into cakes for household use, or is ready for the manufacture of pencils or crucibles. The average formula for the mixture is: graphite, 80; stearite, soapstone, or talc, 14; alum, 6; but this varies with the purpose to which the material is to be applied. When several different kinds of graphite have to be employed, the richest in carbon is first mixed into the alum solution. By this process graphites previously regarded as incapable of being compacted are utilisable, and are improved in polishing power; for pencils, the material may be hard without being brittle, and black without being soft; while crucibles made from the treated graphite are at once harder, more durable, and lighter.—W. G. M.

#### (B).—RESINS, VARNISHES.

*An Investigation of the Resins: The Gum Benzoin of Siam.* F. Ludy. Arch. d. Pharm. 231, 461.

THIS substance, whose exact botanical source is unknown, contains, according to various authors, benzoic and cinnamic acids, styrolene, and vanillin; while the present investigator finds in it two alcohols—benzoresinol and siarresinotannol—combined with benzoic acid, traces of a very aromatic benzoic ether, vanillin (0.15 per cent.), and benzoic acid.

*Siarresinotannol* ( $C_{15}H_{14}O_4$ ) is obtained, as an amorphous brown mass, by dissolving the gum benzoin in dilute soda, precipitating the sodium derivative of benzoresinol by ether, and evaporating the filtrate. It forms a potassium derivative ( $C_{15}H_{13}O_4K + H_2O$ ), and an acetyl derivative ( $C_{15}H_{13}O_4 \cdot COCH_3$ ), both amorphous. Nitric acid yields with it picric acid when concentrated, and when dilute phlophaphene.

By precipitating the ethereal extract of this gum-benzoin with petroleum ether, the benzoates of benzoresinol and siarresinotannol are readily obtained, and of the following composition:—Benzoic acid, 38.20 per cent.; benzoresinol, 5.1 per cent.; siarresinotannol, 56.7 per cent.

Siam benzoin therefore differs, as to its composition, from Sumatra benzoin.—E. R. B.

##### PATENT.

*Improved Insulating Material for Electrical Purposes, and Method of Producing same.* A. Gentsch, Vienna. Eng. Pat. 16,851, September 7, 1893.

ACCORDING to this invention mineral resins, more especially ozokerite, asphalt, and amber, are subjected to distillation in a closed still to a temperature of 100°. After the mass has been heated until gases, vapour, or oils cease to escape, it is allowed to cool. In that condition it is of pliable consistency, and may either be used alone or incorporated with other substances for insulating cables, such as resins, fats, or oils, the proportions of these being from 30 to 70 per cent. By this method the inventor proposes to remove those substances present in fossil resins, which prejudice or deteriorate the insulating properties.—D. B.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*Leather and Glove-making Industry in Spain.* J. Soc. Arts, 42, 1894, 766—767.

SKINS used for the manufacture of gloves in Spain are kid for the first quality and lamb for the second quality. The United States Consul at Cadiz says that the skins are placed in a lime-water bath for four or five days, after which they are taken out and extended upon a bench called *caballete*, and with a curved knife that has no cutting edge, known as the *descarnador*, are depilated, then turned over, and by means of another knife of dull edge the flesh is cleared from them. After this the skins are worked with another unsharpened knife, then stamped with a rammer and rasped again. They are then put into a bran-water bath until they float on the surface, when they are taken out and the bran removed by means of a slightly-sharpened knife, which is passed over the skin from side to side. When thus cleansed they are placed in a large earthen vessel containing beaten yolks of eggs and wheat-flour, and agitated for a short time, then alum solution is poured into this bath in the proportion of three pounds for every 24 skins. In this wash they are macerated with the feet for two or three hours, after which they are taken out, washed, pressed to remove the water, and placed to dry. The skins are prepared for colouring by rasping and softening them, placing them upon a lead table, and saturating them with urine or potash. Aniline dyes are employed to produce the colours, and the brilliancy is obtained by means of polishers. Russia-leather is sometimes used for making gloves. Its preparation commences like that of the common leather, by removing the grease and depilating the skins with lime. They are afterwards macerated in a bath of fermented rye-flour dissolved in water, and they are kept in this bath for two days. They are then cleaned and washed in running water. The tanning is performed by employing the bark of the birch, pine, or willow trees, in which decoction the skins are submerged and agitated twice a day for a fortnight and sometimes for as long as six weeks. After this they are rubbed and scraped upon boards, and once cleaned, extended on a table, and impregnated on the flesh side with the oil of birch-bark tar, and then immediately stretched, in order to give them the necessary flexibility. Once saturated with this oil, the hair side is bathed with a solution of alum, then dried, and a fluted cylinder passed over it. It is now ready for colouring. The red colour of Russia-leather is obtained by boiling red sandalwood and logwood in lime-water, containing a small quantity of carbonate of potash and oxide of sodium, which infusion is

poured into sacks, formed by two skins sewn with the hair side inwards. The liquid is kept inside, until it penetrates the skin. The colour can also be applied with a brush, giving the skin continual coats of the infusion named above. When the skins are coloured, the ordinary methods are proceeded with, to soften and polish. Knapp-leather is prepared by two methods: the first consists in submerging the skin in a bath containing 5 per cent. of lime, where it is kept until well impregnated, then taken out and left to drip: it is afterwards placed in another bath, composed of 3 to 5 per cent. of potash soap, in which it is tanned. The second method, by which better results are obtained, consists in mixing an alum solution with the soap, thus obtaining a compound, in which the skin is kneaded; after this it is washed and dried. The Knapp-leather obtained by means of the alum soap has a white surface, and is soft and agreeable to the touch. White leather is prepared from kid, goat, and sheep skins, by submitting them to the preparatory operations of tanning, lime being employed for cleaning and depilation. The skins are well washed, to remove the grease, and, with the object of effecting this and of swelling them, they are placed, after being cleansed, in a bath of oat-water, where they are kept for two or three days; they are then taken out, washed, and wrung out by twisting. They are then immediately put into the tanning bath, which is composed of 750 grms. of alum, 30 grms. of marine salt, and about 22 litres of water for every 10 skins. To operate with it, a hot mixture is placed in a tub, and when it begins to cool, a skin is submerged in it once or twice until it is well soaked; it is then taken out and the others treated in the same way. They are then placed, without drying, one over the other, and are left for two or three days. They are afterwards twisted and hung up to dry on long poles, called *pertigos*. During this drying, the skins become wrinkled and very rigid. In order to lengthen them and to remove the wrinkles, they are rubbed longitudinally against the convex part of a curved bar. The preparation of glove-leather requires especial tanning, every operation being performed in an exceedingly careful manner, so that the skins may be completely cleaned, softened, and given that elasticity necessary to adapt them to the form of the hand, and to always preserve their grain intact. The preliminary operations of preparing this leather are the same as those indicated for white leather, the tanning being different. When prepared, they are introduced and macerated with the feet in a bath composed of wheat-flour, yolk of eggs, alum, marine salt, and water in a sufficient quantity to form a sort of a light paste, which acts in the following way. The flour swells the skin by the combination of its glutinous parts with the alum absorbed by it, the yolk of the eggs acts not only by its albumin, but also by the oil which it contains, and gives to the skin the softness and resistance necessary for leather intended for gloves. Once well soaked in this paste, the skins are taken out, and, after drying, slightly moistened and stretched as rapidly as possible. They are then placed by dozens inside a cloth, and pressed by the feet, to soften them. They are then submitted to the polisher, by whom they are stretched and polished. This operator removes the last vestige of flour which may remain. They are then whipped and beaten to give them softness. When the leather is intended for the manufacture of embroidered gloves, it is polished with a glass polisher on the hair side, or covered with a light bath of albumin, Senegal gum, or soap. A dozen tanned kid-skins cost from about 20s. to 25s., and these will make from 20 to 21 pairs of gloves. A dozen tanned lamb-skins cost about the same, but will make from 44 to 48 pairs of gloves.

#### PATENT.

*Improvements in the Art or Process of Tanning Hides or Skins.* W. Zahn, Newark, U.S.A. Eng. Pat. 24,463, December 19, 1893.

To produce a waterproof, soft, and elastic leather, in quality superior to those produced by other systems of tanning,

the skins prepared as usual for tanning are left for from one to three hours or more, according to their thickness, in a weak ( $\frac{1}{2}$  per cent.) solution of chromic acid, and are then drained. They are now transferred to a bath of chromo alum (or other chromic oxide salt) containing 70 or 80 lb. of the salt per 1,000 lb. of skin and sufficient water to cover the latter. Here, with the aid of a paddle-wheel, the sulphide of an alkali or alkaline earth is mixed in with the solution, with the result that the chrome alum is converted into a basic salt; and the chromic oxide reduced from the chromic acid in the skin, forms chromium hydrate. In from 10 to 15 hours the hides may be removed from this bath, washed, and finished in the ordinary manner.

#### XVI.—SUGAR, STARCH, GUM, Etc.

*Phoma Betae, the Beetroot-destroying Organism.* Frank. Zeits. Ver. Rübenzuck.-ind. 44, 264.

The author contends that this pest, which was observed during 1893 in almost every part of Germany, is not identical with "*Sporidesmium putrefaciens*" or "*Peronospera Schachtii*," which Kühn recognised 20 or 30 years ago as the cause of the core-rot (compare, however, *Hollrung*; this Journal, 1894, 264).

It is now positively established that the organism exists in the seeds, and may be the cause in some instances of mildew in the young beetroots. The threatened infection by *Phoma Betae* is only to be avoided by disinfection, a fact likewise recognised by Hellriegel and Klarson. As observed by Hellriegel, carbolic acid is effective as a disinfectant, but it weakens the germinative power of the

seeds. The use of the following mixture is recommended.—Copper sulphate (4 kilos.) is dissolved in water (100 litres), and into the solution is stirred the paste resulting from 4 kilos. of freshly-slaked lime. With this liquid the seeds are thoroughly moistened and allowed to remain therewith for 18 hours, when they are washed; thorough washing prior to sowing is unnecessary. It is well in the case of fields infected with *Phoma* to sprinkle the soil with the above-described mixture, which does not harm the roots in any way; if any diseased roots are discovered it is best to remove them.—A. R. L.

*Estimation of Sugar in Beetroots.* Kroecker. Zeits. Ver. Rübenzuck.-ind. 44, 322.

THE author finds that both cold and warm digestion of the roots, as also when sufficient basic lead acetate was added to the juice to produce alkaline reaction, leads to results which are too high. Cold alcoholic digestion yields too low results; warm alcoholic extraction, however, gives the same values that are obtained by Scheibler's extraction process.—A. R. L.

*Galvanised Iron Sugar-Moulds with an Internal Coating.* E. Donath. Zeits. angew. Chem. 1894, 232.

THE drawbacks attending the use of janned and galvanised sugar-moulds have been successfully overcome in a new mould, which is made of galvanised iron provided with an internal coating. This coating consists of a strong solution of sodium silicate mixed with china clay and either finely-ground dolomite or a mixture of chalk and magnesite. The moulds are coated with this mixture and dried at about 60° C. In using these moulds for the first time they should be filled with erude sugar-liquor (*massecuite*); subsequently they can be used for refined liquor. It appears that the small quantity of lime contained in the former renders the coating resistant to the action of water. This coating of the moulds is renewed from time to time.—C. O. W.

*Evaporation and Boiling of Sugar-Liquor (Beetroot-Juice).* J. Lexa. Zeit. Zuckerind. Böhm. 18, 258—275.

THE author criticises adversely several portions of the latest edition of Stohmann's *Handbuch der Zucker-fabrikation*. Stohmann is said to have erroneously described the Rillieux multiple-effect evaporating apparatus first constructed in 1848. The author further asserts that Peelet, Otto, Walkhoff, and Stammer have all completely misunderstood Rillieux' drawings and his description.—A. R. L.

*The So-called Scum Fermentation in the Javanese Sugar Factories.* Prinsen Gurlings. Zeits. Ver. Rübenzuck.-ind. 44, 297.

THE above-named phenomenon consists of a decomposition of the degradation products resulting by the action of lime at the boiling temperature on invert sugar; it must therefore specially relate to the decomposition of glucinic acid, which latter in the free state or in hot acid solution decomposes into acetic, formic, and humic acids together with carbonic anhydride. The glucinic acid can be destroyed by rendering the thick liquor or green syrup faintly acid with sulphurous or phosphoric acid and boiling, the scum being subsequently skimmed off. It is, however, preferable to prevent the formation of glucinic acid, and this can be accomplished by defeccating the cane-juice with 2—3 per cent. of lime at a temperature not exceeding 60°, and saturating with cold carbonic anhydride, whereby the saccharine and likewise the invert sugar is decomposed. Practical experiments on a large scale showed, however, that when either alternative is adopted scum fermentation no longer occurs.—A. R. L.

*The Invertive Action of Glycerol.* E. Donath. J. prakt. Chem. [2], 49, 546—548.

REFINED sugar was dissolved in ten times its weight of pure commercial glycerol of sp. gr. 1.2556 at 17.5° (thus

containing about 97 per cent. of glycerol), and the solution heated in an open dish for half an hour at 130°. The liquid after dilution now showed, on being heated with Fehling's solution, cupric reduction equivalent to 4.2 per cent. of sugar inverted. The experiment was then carried out using the same glycerol diluted with 10 per cent. of water; the quantity of inverted saccharose indicated by the copper test was in this case 7.3 per cent. In a third experiment, in which the glycerol was diluted with 20 per cent. of water, 15.3 per cent. of inverted saccharose was indicated. When the sugar was dissolved in the last-mentioned glycerol containing 20 per cent. of added water, and the solution was heated in a Lintner's pressure flask at 120—130°, it appeared that more than 60 per cent. of the sugar was inverted. By heating a solution of sugar in aqueous glycerol contained in a Lintner's flask at 160° for several hours, the product was lavo-rotatory and of a dark colour, showing that considerable decomposition had taken place. The levulose had probably undergone reversion to some extent.

When heated with glycerol to which 10 per cent. of water has been added, "dextrin" does not appear to be converted into maltose, but a partial conversion of maltose into dextrose is indicated by the increase in the reducing power and decrease in the rotatory power; the inversion of milk-sugar also attains a higher limit than that of maltose, but is nevertheless far from complete. Raffinose is scarcely altered by aqueous glycerol at ordinary pressure, but when heated with it in a Lintner's flask at 125° considerable inversion takes place. Taking into account the fact revealed by these experiments, viz., that glycerol containing 10 per cent. of added water has a greater hydrolytic power than the original substance containing only a slight amount of water, and that an addition of 20 per cent. of water still further enhances the hydrolytic power; also the well-known fact that glycerol combines with water at the ordinary temperature, and again parts with it when heated, the author suggests that it is perhaps this water of hydration in "*statu nascendi*" which brings about the hydrolysis of the sugars.—A. R. L.

*Comparative Defecation Experiments with Beetroot-Juice.* A. Herzfeld. Zeits. Ver. Rübenzuck.-ind. 44, 278.

ACCORDING to the author the beetroot-juices employed in 1893 were better than those of 1892, and when the former were heated at 90° C. for a long time, only a slight amount of invert sugar was formed. The juices were treated at 90° C. in suitable apparatus provided with mechanical agitators, with slaked lime or with caustic lime, and then saturated. The experiments show that the use of milk of lime of 20° Beaumé, which is the plan adopted in practice, is free from reproach, whilst defeccation with dried slaked lime may render the saturation difficult; it is, however, shown that dry defeccation proceeds quicker, better, and more completely, and also renders possible a quicker saturation, probably because in consequence of the formation of calcium saccharate more lime is dissolved. These results are not, however, to be regarded as final, but will be confirmed by comparison with other methods of moist defeccation. Experiments in which the defeccation was conducted in the cold yielded very good liquors free from invert sugar, but the nature of the mud obtained in these cases increases the difficulty of filtration to such an extent as to render the process an impossible one.—A. R. L.

*Purification and Decolorising of Beetroot-Juice and Sugar Solutions.* Steffen and Drucker. *Sucr. indigène*, 43, 501.

THE liquor from the filter-presses is cooled to 30—35° C. and treated with 80, until it contains 1—2.5 grms. per litre; the cold solution is then filtered over 1—2 per cent. of animal charcoal, the filtrate neutralised with lime or other bases, and after mechanical filtration the liquor is boiled. Even when animal charcoal is entirely dispensed with, the liquor is said to be so pure and colourless that "refined *massecuite*" can be directly obtained from it. The green syrup from the latter, moreover, possesses the

ordinary quality of that obtained in the refinery. The same results can be obtained by similarly treating refinery syrups or solutions of raw sugars by the above-described process.

—A. R. L.

*Tables showing the Amounts of Coal and Steam required in the Manufacture of Sugar.* Claassen. Zeits. Ver. Rübenzuck.-ind. 44, 173.

THESE tables, which the author has calculated for the coal and steam required for the evaporation, boiling, and warming of the juice (not for the entire need of the manufacture), show at a glance the efficiency of the various evaporating and heating plants, and are therefore of great value for comparative calculations. The values are not, of course, of universal application, but generally by means of a calculation the amounts of steam and coal required for any description of apparatus, as well as the cost of the same, may be approximately arrived at. The important fact revealed by the tables is that in multiple-effect plant an increase in the number of members beyond 4, or at most 5, is not attended with profit, and that such evaporating plant as that of Rillieux and of Lexa may be classed among the most efficient.—A. R. L.

*Fermentation of Molasses.* J. Effront. Monit. Scient. 8, 161.

THE author arrives at the result that the non-fermentation of the whole of the sugar present in molasses is to be traced to the presence of certain bacteria. The action of these can be arrested by treating the molasses with a sufficient quantity of antiseptic agents or acids, which must not, however, be also enough to arrest the fermentation of the yeast.

For this purpose, tannin (25 grms.) is added to molasses (100 kilos. diluted to 18° Balling°); after subsiding, the clear liquid gave the normal yield of alcohol. Pieric acid (25–30 grms.) to molasses (100 kilos.) also gave good results; it must, however, be used with great caution on account of the poison which it imparts to the residues. The simplest and most convenient substance to remove these bacteria appears to be egg-albumin; the quantity obtained from three to four eggs is sufficient for 100 kilos. of molasses. Alumina and also hydrofluoric acid serve the same purpose.—A. R. L.

*Gravimetric Methods for Estimating Sugars by their Cupric Reducing Power.* L. Grünhut. Chem. Zeit. 18, 447.

See under XXIII., page 845.

#### PATENTS.

*Improvements in the Method of Separating Metals from Ores and from other Mixtures of Insoluble Substances therewith.* E. R. Besemfelter, Grosse, Mochbern, Silesia. Eng. Pat. 23,619, December 8, 1893.

See under X., page 815.

*Process for Purifying and Decolorising Saccharine Juices and Solutions.* B. Lach and H. Benies, Vienna, Austria. Eng. Pat. 8463, April 28, 1894.

THE process consists in treating the saccharine juices and solutions (1) with the products obtained by heating to incandescence, with exclusion of air, animal refuse (blood, flesh, hide, horn, hair, &c.), mixed with 5 per cent. of carbonate of potash, carbonate of soda, caustic potash, or caustic soda; or (2) with the waste products resulting from the manufacture of ferrocyanide of potash.—A. R. L.

\* In the Balling areometer  $d = \frac{200}{200 - n}$  where  $d$  = specific gravity and  $n$  = weight of water displaced when the instrument sinks to a certain division of the scale. In cases of liquids lighter than water the formula becomes  $d = \frac{200}{200 + n}$ .

*Improvements in the Manufacture of White Sugar and the like from Molasses, and in Centrifugal Apparatus for use therein.* E. Hübner, Domaglice, Bohemia, Austria. Eng. Pat. 9436, May 12, 1894.

THE patentee claims a process for the manufacture of white sugar and the like from molasses in centrifugal machines fitted with plates disposed radially, or in parallel positions with perforated cylinders, these plates being fitted with flanges to regulate the dimensions of the cells thus formed. The drum of the centrifugal is charged with molasses, and into it is led a jet of steam from a pipe. The general construction and combination of the several parts of the apparatus employed is also claimed.—A. R. L.

*A Process for Deodorising and Bleaching Dissolved or Fused Amylaceous Materials.* C. D. Abel, London. From L. König, Berlin, Germany. Eng. Pat. 9674, May 17, 1894.

OZONE or ozonised air, prepared by passing oxygen or air through apparatus in which there is a silent electrical discharge produced by alternating high-tension currents, is blown from fine apertures through the liquid (solutions of soluble starch, dextrin, or gum); or the latter is passed in fine streams through a space charged with ozone. The quantity of ozone employed is such that, after acting once or several times on the liquid, it is mostly absorbed; the action is continued until the desired effect is produced.

—A. R. L.

*Improvements in the Production of Dextrins and Leiocomes.* C. D. Abel, London. From C. Pieper, Berlin, Germany. Eng. Pat. 9675, May 17, 1894.

THIS invention relates to a process of obtaining dextrins and leiocomes from starch by the action of ozone or of ozonised air. The starch (purified amyllum, fecula, &c.) is impregnated in the usual manner with acid—preferably hydrochloric acid—and allowed to dry. It is then heated in suitable roasting apparatus provided with inlet and outlet tubes. While thus heating the starch to the usual temperature to convert it into dextrin, a current of dry or moistened ozone is passed into the cylinder through the said inlet or inlets, leiocome being produced. The principal reaction takes place while the material is giving off aqueous vapour. Dextrins and leiocomes prepared by the above process are said to be clearer and brighter than those at present in the market; besides which they have, when dissolved, a pleasant odour and taste instead of the well-known repugnant odour given off under like circumstances by the ordinary commercial products.—A. R. L.

#### XVII.—BREWING, WINES, SPIRITS, Etc.

*The Specific Character of the Fermentative Functions of Yeast Cells.* A. J. Brown. Proc. Chem. Soc. 1894 [141], 159.

THE usually accepted view as to the cause of the exhibition of the fermentation functions of yeast cells is that it is a starvation phenomenon brought about by want of free oxygen during the life of the cells in a fermentable liquid; or, more briefly, that it is a phenomenon of "life without air." This view was originated by Pasteur, a full account of the experimental results which led him to formulate this theory being given in Chapter VI. of his "Études de la Bière."

In a paper on the influence of oxygen on alcoholic fermentation (this Journal, 1892, 237), attention was called by the author to the fact that some of the experimental results described appeared to be contradictory to Pasteur's

theory. Further work on this subject has led him to think that a review of the experiments on which Pasteur's theory rests, in conjunction with the results of some of his own, will not be out of place at the present time.

Pasteur's experiments may be divided into two classes, one containing experiments which appear to have suggested his theory, the other containing experiments undertaken for the purpose of proving its truth. It is not proposed to discuss the experiments in the first class, as, although they demonstrate most important facts regarding the life and growth of yeast, they afford no proof that fermentation is a consequence of "life without air."

The attempted proof of this theory lies in those experiments by which Pasteur determines, under varying conditions of aëration, the proportion of the weight of the yeast formed to the weight of sugar fermented. This ratio, or proportion, of yeast to sugar is, Pasteur considers, an expression of fermentative power; and when considering the ratios established by different experiments, he treats them as comparable with each other. By thus comparing fermentative powers of yeast cells under varying conditions of aëration, he arrives at the conclusion that when aëration is perfect, fermentative power ceases, and when aëration is reduced, fermentative power increases; the proof of Pasteur's theory, indeed, rests upon this conclusion.

As so much turns on Pasteur's interpretation of the experimental results by which he determines fermentative power, it is desirable to test it as thoroughly as possible. The ratio of yeast formed to sugar fermented in any experiment is an expression of fermentative power; but if it is found desirable to compare fermentative powers determined from the results of two or more experiments, it becomes necessary to make sure that either the total fermentative power, or some known fraction of it, has been measured in each case, otherwise no true comparison can be made.

If the amount of yeast formed during fermentation were in direct proportion to the sugar fermented, the ratio of yeast to sugar would remain constant, however much or little sugar were available; but experiments made by the author show conclusively that such is not the case. The amount of sugar available during fermentation is a factor that has but little influence on yeast increase; *there is, in fact, no direct proportion between weight of yeast formed and sugar fermented.* In order to show that the total fermentative power of yeast has not been measured in Pasteur's experiments, a fermentation was carried on under aerobic conditions until the sugar originally present was decomposed. Afterwards, using the principle of overcrowding as a means of preventing reproduction, the crowded cells were fed with more sugar. Feeding was carried on at intervals until the yeast had fermented three times the amount of sugar originally present at the beginning of the experiment, but no increase in the weight of yeast took place. Thus the fermentative power of the yeast was found to be at least threefold what it would have been if determined in the manner adopted by Pasteur.

Apart from the fact that Pasteur fails to prove the truth of his theory by comparing fermentative powers, his hypothesis is further weakened by the fact that none of the results of his experiments are contradictory to a hypothesis opposed to his. The aerobic and anaerobic life-history of yeast, as demonstrated by Pasteur, can be accepted without the truth of his hypothesis regarding fermentation being admitted. There is no *prima facie* reason why the fermentation functions of yeast cells should not be exercised independently of the cells' environment, so far as the presence or absence of free oxygen is concerned; and nothing in Pasteur's experiments contradicts this.

#### Utilisation of Waste Carbonic Acid Gas in Breweries. A. Marcet, Trans. Inst. Brewing 7, 199—223.

This paper gives a historical sketch of the development of the plan (first carried out at Guinness' Brewery in 1890) of collecting and compressing the carbonic acid produced in breweries during fermentation and a description of the apparatus and method employed. (See also XXIII., page 844.)

The quantity of carbonic acid evolved during fermentation is approximately equal in weight to the alcohol produced. The rapid evolution of carbonic acid begins in breweries about 20 hours, in distilleries about 6 to 8 hours after "pitching," and for some time after that the evolution is rapid and regular enough to allow the gas to be drawn off by the compression pumps without fear of drawing in air. If air is drawn into the compression pump it can be got rid of by a special release valve. For collecting the gas the ordinary parachute or skimmer is used with raising and lowering gear, allowing it to be kept just above the head of the yeast. The level of the carbonic acid in the vat is ascertained by an ordinary collodion air balloon which floats on the surface of the carbonic acid. The collection is stopped as soon as the evolution of gas becomes slow.

The compressor used is of a three stage type, the gas being purified after the first stage (15 lb. compression) by passing through water, strong sulphuric acid, and a weak solution of permanganate of potash. For purification 100 lb. of carbonic acid require  $5\frac{1}{2}$  lb. of sulphuric acid,  $\frac{3}{4}$  oz. of potassium permanganate and  $\frac{1}{2}$  oz. of sodium carbonate. The pressure in the third stage reaches about 60 atmospheres, and from this the gas passes to the condensing coils, cooled by water and is liquefied. The intermediate collecting vessel and the receivers are suspended on Salter's balances so that the attendant can at once see when they are full. Obtained in this way the gas has a purity of 99.5 per cent., and is odourless. The receivers or cylinders are made of mild steel and are either solid drawn or lap welded. They are tested to 3,000 lb. on the square inch, the normal filling pressure at ordinary temperatures being about 750—800 lb. In some tests made a year or two ago by the Scotch and Irish Oxygen Co. of Glasgow, vessels of this type filled with oxygen at 1,800 lb. to the square inch were allowed to fall 35 ft. on to iron blocks and otherwise severely treated without damage further than bending and slight loss of shape.

The cost of the liquid gas (inclusive of labour and interest on capital) is about 3*l.* 10*s.* and its selling price at present about 18*l.* per ton.

The liquefied carbonic acid is now being used for raising beer, in place of the ordinary pumping-engine. A reducing valve is attached to the cylinder, reducing the pressure to about 4 lb. per square inch, or whatever pressure is required to raise the beer from the cellar to the tap. An air-tight connection is made to the top of the barrel and the pressure not only sends the beer up in good condition but is said to improve it as the level gets lower in the barrel. The antiseptic qualities of the gas and its freedom from germs also make its use preferable to that of the ordinary beer-engine. Liquid carbonic acid has been found advantageous in bottling beer, beer thus bottled maturing in three days in place of three weeks. It is also used for a variety of purposes from aerating water and bread to hardening armour plates.

DIAGRAM OF CYCLE OF REFRIGERATING MACHINE.

The author considers, however, that one of its most important uses will be in refrigerating machines. The accompanying diagram will explain the character of the apparatus and cycle of operations. The principle of the machine is

of course, the same as that of the ammonia or ether refrigerating machines, and the degree of cooling can be regulated by the pressure under which the liquefied gas is evaporated, and it is equally easy to cool water, say from 70—30 F., or to maintain brine at say +10° F. or -10 F. Under 35 atmospheres pressure, for instance, liquid carbonic acid boils at 30° F. The surfaces of the evaporator coils are so proportioned that all the liquid which enters the lower end of the coil is evaporated by the time it reaches the top end, and thus the maximum efficiency is obtained. It has been said that as carbonic acid will not liquefy at temperatures above 87° F. (its critical point) its possible duty as a refrigerant in the tropics would be very low. Experience with machines of considerable power using condensing water at 90—95° has, however, shown the loss of efficiency to be very slight, and 40 or 50 carbonic acid refrigerating machines are working satisfactorily in the tropics. The carbonic acid refrigerating machine has the advantage over the ammonia or ether machines that a leak is not so unpleasant or dangerous.

In the discussion T. W. Thorpe stated that in his brewery about 1 ton 2 cwt. of liquid carbonic acid was obtained from 600 barrels of wort, and that the actual cost of collecting and compressing was  $\frac{1}{2}$ d. per lb., a second  $\frac{1}{2}$ d. per lb. being paid as royalty. In their case glass coverings over the tuns had been introduced without any deterioration of vigour of fermentation, and with increased freedom from germs. The Aerated Bread Company used their liquefied carbonic acid for raising their bread. Sir A. S. Haslam was not prepared to admit that there was no particular falling off in efficiency in the carbonic acid gas machine at temperatures at or above its critical point. The critical point of carbonic acid is 31° C. (88° F.), and of ammonia 117° C. (or 232° F.). At 68° F. the latent heat of vaporisation of ammonia is 540 and of carbonic acid 63°, whilst at 86° that of ammonia is 524, and of carbonic acid only 19°. He considered therefore that, at least at high temperatures, the ammonia machines must be more economical than the carbonic acid machines. The ammonia machine too, only required a pressure of 90 to 150 lb. (according to the temperature of the condensing water) while the carbonic acid machines would require from 900 to 1200 lb. pressure. He believed 1 ton of coal with an ammonia machine would do as much work as  $1\frac{1}{2}$  tons with a carbonic acid machine. Dr. Sykes believed the relative economy of working of the ammonia and carbon dioxide machines to be about equal.

In replying to the discussion the author showed a curve the pressure produced in the cylinders by increased temperature. At 113° F. the pressure was only about half that at which the cylinder was tested. In the tropics, where in the sun a temperature of 160° F. might possibly be reached, the pressure was of course considerably increased, but experience showed that even then there was practically no danger. Referring to the loss of efficiency above the critical point of the liquefied gas he said that a large machine to make four tons of ice per day had been run for a week with the cooling water at 100° F. There was of course a loss of efficiency (as was the case whatever material was used), but it was far less than they had been led to expect. These machines were working satisfactorily in the tropics, in some places side by side with ammonia machines, so that any excessive loss of efficiency would have been at once detected.—L. T. T.

*Hansen's System of Pure Yeast Culture in English Top Fermentation.* A. Jørgensen. Trans. Inst. Brewing, 7, 227—254.

In this paper the author upholds Hansen's system of employing "pure yeast" from one cell against Van Laar's "composite yeast" or yeast composed of two selected types. The one type of pure yeast has now been proved to be successful both in extended experimental brewings, and also in practice in many breweries on the Continent and in England. Secondary fermentation takes place regularly and normally, and does not need the presence of a second type of yeast. Experiments made in

Jørgensen's laboratory and also by A. K. Miller at Ardwick Brewery, Manchester, with absolutely pure cultures proved that one single species can carry through both the primary and secondary fermentation and give excellent beer. W. R. Wilson's practical experience at Coombe's Brewery fully confirmed these results. On the other hand, careful experiments were conducted by the author in conjunction with Holm and F. Petersen, in his own laboratory and in breweries, with Van Laar's composite yeast (obtained from Van Laar's Burton Company) and with mixtures of culture-yeast types which had already been tried singly. These experiments showed that in worts pitched with these composite yeasts the ratio of the two types altered as the fermentation proceeded, one type gradually increasing with the gradual suppression of the other and weaker type. Sometimes this suppression was almost complete in one fermentation, in others it was but partial, but continued to total extinction when the yeast from one fermentation was used to start succeeding ones. The author concludes that "Van Laar's composite yeast is not able to preserve the constancy of ratio between the species of which it is composed, but has to be renewed continually if wanted to be kept unaltered." His experiments show that in some cases if type *a* and type *b* of yeast each give satisfactory results in a brewery, a mixture of those types, in the same brewery and under, as far as can be seen, identical conditions, gives unsatisfactory results. Thus the "one species pure yeast" system both gives thoroughly satisfactory results, and is much more certain, regular, and reliable than the "composite yeast" system advocated by Van Laar.

The author also upholds Hansen's claim to be the first to cultivate and investigate really pure yeast cultures containing only a single species.

In the discussion on the paper, Tanqueray said his own experience showed that where a large quantity of pure one-species yeast was used in pitching with the ordinary yeast of the brewery it would crowd out the old yeast, and if, after a short time, a second charge of the same pure yeast were introduced, it would entirely replace the old yeast. This both confirmed and extended Jørgensen's results. G. H. Morris disclaimed any desire on the part of English brewers to depreciate Hansen's work. He would like to see more attention paid to the chemical composition of the wort at different stages and under different conditions, and especially to their carbohydrate composition. His own experience was that each variety of pure yeast had one definite limit-attenuation, below which no further fermentation took place with that yeast in a reasonable time. He would like to see more definite figures brought forward to prove that the single-cell pure yeast gave a true secondary or after fermentation. Dr. Sykes said since the meeting of the Institute in January last, his own actual observation had compelled him to reverse the views he then expressed and admit that single-cell pure yeast could be successfully used and did produce beer satisfactory as regards both flavour and after fermentation. Fellowes did not consider the evidence regarding secondary fermentation was satisfactory. Whilst Wilson was obtaining good results with single-cell yeast, others were equally satisfied with the results from composite yeast. In replying, the author pointed out that the results described by Tanqueray of the crowding out of the old yeast by pitching with pure single-cell yeast may prove useful in all cases where a period of transition from the old to the new yeast is desired.—L. T. T.

*Affinity-Constants of Weak Acids.* R. W. Wood. Amer. Chem. J. 16, 313—325. (Compare this Journal, 1894, 515.)

THE author has continued his experiments on the action of various substances in retarding the fermentation of starch by diastase. By employing a new constant-temperature bath, several possible sources of error are eliminated. He has investigated the effects of changes of temperature on diastatic action, and finds that 55° C. is the most favourable temperature. The retarding influence of acids is due to the presence of hydrogen ions and from his measurements

on weak acids he has been able to calculate their affinity-constants, which agree fairly well with those obtained by Ostwald from the measurement of electrical conductivity.

The neutral sodium salts of the weak acids have also a strong inhibitory action on diastase, probably due to the presence of hydroxyl ions formed by the hydrolytic dissociation of the salt. The author's method does not apply to the salts of exceedingly weak acids, and consequently no satisfactory comparison can be made with the numbers obtained by Shields. The action of salts on the corresponding acids obeys the law of mass action. In conclusion the author points out that the method which he has adopted may be applied to the determination of the relative affinities of the organic bases.—J. S.

*Composition and Analysis of Yeast.* P. Guichard. Bull. Soc. Chim. 1894, 11, 230.

*Improvements in the Process of and Apparatus for Drying Distillers' Washes and the like, and for Removing the Acids therefrom.* Actien Maschinenbauanstalt, vorm. Vemulth and Ellenberger, Darmstadt, Germany. Eng. Pat. 11,153, June 7, 1893.

THE production of feeding-cake from distillers' wash, &c., usually involves the evaporation of large quantities of water. The object of this invention is to do away with that expensive operation as far as possible, by making use of a process of precipitation and filtration. For this purpose the wash is raised to boiling, treated with alum (1 lb. to 5,000 galls.) to precipitate the dissolved albuminoids, and filtered through an improved filter-press. The latter consists, as usual, of a row of cells and intermediate pairs of filter-plates separated by ribbed frames. The wash is supplied by a common main-pipe simultaneously and independently to all the cells; and, moreover, each filtering partition is fitted with a separate discharge-cock. In consequence of this arrangement, filtration is rapid and uniform at all points of the press; and the cells may be made much wider, and therefore the press-cakes thicker, than usual. When the cells are filled with insoluble matter a further portion of water is expressed from the same, by admitting air at high pressure to every alternate filtering partition, and the press-cakes from the frames are finally completely dried in any convenient manner. The water thus mechanically removed from the wash, carries with it the bulk of the organic and inorganic acids, and other valueless substances originally present. The cake being deprived of these bodies, becomes correspondingly richer in albuminoids, &c., and compares very favourably with cakes produced in the usual way.—H. T. P.

*Improvements in the Manufacture of Yeast and the Distillation of Spirits.* L. Lederer, Dalston. Eng. Pat. 12,837, June 30, 1893.

THE special points of the process are: (1) The use of green malt for saccharifying purposes; (2) the employment of a previously-prepared "fermenting medium"; (3) the carrying out of the whole of the operations, fermentation and distillation included, without removal of the grains. The fermenting medium is prepared by making a strong mash of equal parts of green malt and rye at  $62\frac{1}{2}$ — $65^{\circ}$  C., allowing the mixture to acidify for 20—24 hours at  $48^{\circ}$  C., and finally pitching it at  $20^{\circ}$ — $24^{\circ}$  C. with fresh distillers' yeast. In about 10—12 hours the temperature rises to  $34^{\circ}$ — $35^{\circ}$  C., and the yeast is ready for use. The main mash is made in the usual way in an apparatus consisting essentially of an ordinary mash-tub, into which a framework carrying a rotatory stirring arrangement, and heating and cooling coils, can be lowered. Raw grain (maize, &c.), if used, is soaked and boiled prior to its admixture with the cold mash of green malt, &c., and saccharification is allowed to proceed at  $65^{\circ}$  C. for 15—30 minutes. The mash is then cooled to  $35^{\circ}$  C., mixed with the above fermenting medium, further

cooled to  $28$ — $30^{\circ}$  C., and run into fermenting vats. In the latter, the liquid is diluted until it measures 75—85 gallons per 112 lb. of grain used, and acidified with sulphuric acid (2—2½ per cent.).

The yeast which forms is skimmed off, washed twice by decantation with water, and is then ready to be pressed. The fermented mash is distilled in the usual way for the production of spirit. It is claimed that this process is more economical and rapid (the whole operation, distillation included, requires 60 hours) than the older ones; and that a much higher yield of whiskey, rectified spirit, &c., of excellent quality may be obtained by a single distillation, without having recourse to rectification.—H. T. P.

*Improvements in the Clarification and Preservation of Syrups, Extracts, Wines, Beers, Mineral Waters, and other Liquids.* R. E. Evans, Stratford-on-Avon. Eng. Pat. 11,373, July 26, 1893.

THE inventor's claim is for an improved clarification effected by using aluminium hydrate, either alone or in conjunction with gelatin, isinglass, algin, albumin, or other materials.

The liquid to be treated is mixed with a suitable quantity freshly prepared aluminium hydrate; or alum is first added and then a judicious quantity of carbonate of potash to precipitate the alumina. The clarification may be materially assisted by the addition of gelatin, isinglass, &c.—about one part for every part of alumina.—L. de K.

*Improvements in Apparatus for the Preparation of Malt.* R. R. P. Schmiedeecke and E. O. Gade, Berlin, Germany. Eng. Pat. 1717, January 26, 1894.

AN improved system of pneumatic malting. The germinating grain is contained in a horizontal cylinder, free to rotate on a fixed tubular axis, through which the necessary air is supplied. The central tube is provided with air-outlet holes only on one half of its circumference, and is surrounded by a second tube, from which radiate, like the spokes of a wheel, a series of perforated air-conveying pipes. The outer tube, &c., rotates with the cylinder and serves as a species of slide-valve, air being admitted to the pipes only during their passage over the apertures in the fixed axis. Normally, the said apertures face downwards, resulting in air being supplied to the pipes as they revolve below the axis (and consequently are submerged in the malt); but the latter may be set at any angle, according to the degree of aeration desired. A throttle-valve, mounted inside the axis, and capable of being slid to any desired point, serves to divert the bulk of the air-current to any particular section of the cylinder which may happen to become overheated. H. T. P.

*Improvements in Carbonic Acid Pressure Apparatus for Vessels from which Liquids are Retailed.* N. Browne, London. From P. Beck, Augsburg, Bavaria, Germany. Eng. Pat. 1926, January 29, 1894.

See under I., page 788.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY AND WATER PURIFICATION, DISINFECTANTS.

### (A).—CHEMISTRY OF FOODS.

*Margarin compared with Natural Butter as regards Digestibility and Nutritive Value.* A. Jolles. Monatsh. Chem. 15, 147—163.

VARIOUS statements have been made as to the relative values of margarin and genuine butter as foodstuffs, the

general outcome of which is, that whilst there is not much to choose between the two as regards digestibility and nutritive value, butter has a slight advantage over margarin in these respects. The author has carried out a long series of observations with a dog fed during four consecutive periods with butter and margarin alternately; the urine and faeces being collected and examined for fatty matter, nitrogenous constituents, &c., so as to obtain the data for determining how much fatty matter passed unassimilated through the animal under each set of conditions as to feeding. In the first and second periods more fat and less carbohydrates were given; in the third and fourth, less fatty matter and more carbohydrates; the fatty matters being butter in periods 1 and 3, and pure margarin in periods 2 and 4. The various articles of food (wheatmeal, sugar, &c.) were carefully analysed and made up into dog-biscuits, so that the amounts of the different kinds of food constituents consumed during each period were accurately known. In this way it was possible to trace out during each period the proportion of proteids, fat, non-nitrogenous matters (starch, &c.), and mineral constituents (ash), which were either digested and assimilated, or passed out undigested in the faeces. So far as fatty matters were concerned, 97 to 98 per cent. was uniformly digested, whether butter or margarin; the figures obtained during the four periods respectively were as follows (in grms.):—

	Period.			
	I.	II.	III.	IV.
Contained in food.....	52.12	42.14	36.84	37.36
"    faeces.....	0.79	0.86	1.05	1.22
Digested.....	51.33	41.28	35.79	36.14
Percentage digested.....	98.1	97.9	97.1	97.3

Hence the conclusion is drawn that under similar conditions of feeding, butter and margarin have practically identical coefficients of digestibility and nutritive value.

—C. R. A. W.

#### *The Proteids of the Kidney-Bean (Phaseolus vulgaris).*

T. B. Osborne. Seventeenth Annual Report of the Connecticut Agricultural Experiment Station, 1893, 186—210.

"THE kidney-bean contains two globulins characterised by great solubility in very dilute saline solutions, and by yielding precipitates with acids, soluble in sodium chloride solutions. One of these globulins, *phaseolin*, probably forms about 20 per cent. of the seed, and has the following composition:—C 52.58 per cent., H 6.84 per cent., N 16.47 per cent., S 0.56 per cent., O 23.55 per cent. The other proteid, *phaseelin*, is much more soluble, remaining in solution after the phaseolin has separated. It is slowly coagulated by heat at temperatures varying with the amount of salts present and the rapidity of heating. It is precipitated by acids, on prolonged dialysis yields insoluble or albuminate modifications, and has more nearly the properties of a globulin than of any other recognised class of proteids. Its elementary composition is: C 51.6 per cent., H 7.02 per cent., N 14.65 per cent., S 0.49 per cent., O 26.24 per cent. In addition to these globulins, the extracts were found to contain an extremely small amount of *protease*."—H. T. P.

#### *The Proteids of Cotton-Seed.* T. B. Osborne and C. G. Voorhees. Seventeenth Annual Report of the Connecticut Agricultural Experiment Station, 1893, 211—217.

CONSIDERABLE practical difficulties were encountered in this investigation, and the results are by no means complete. So far the authors have found that the proteids of cotton-seed comprise:—1. A very small proportion of a substance resembling *protease*. 2. About 16 per cent. of a globulin (styled *edestin*) similar in composition and probably identical with the *vitellin* existing in the seeds of wheat, maize, hemp, flax, &c. *Edestin* is soluble in saline solutions

and has the following composition:—C 51.71 per cent., H 6.86 per cent., N 18.64 per cent., S 0.62 per cent., O 22.17 per cent. 3. A proteid soluble in weak potash, but not in salt solutions. 4. A nitrogenous substance insoluble in either of the above solvents. The total nitrogen of cotton-seed is distributed among these various proteids in the following proportions:—*Protease*, 2 per cent.; *edestin*, 42.3 per cent.; alkali-soluble proteid, 44.3 per cent.; insoluble proteid, 11.4 per cent.—H. T. P.

#### *Normal Chlorine in Spring Waters.* R. Haines.

J. Franklin Inst. 137, 134—139.

IT is probable that the amount of "normal chlorine" naturally existing in spring waters, as distinguished from that due to contaminating influences arising from the life and occupations of man, will be found to be fairly constant in the waters of any particular locality, as has been found in Massachusetts, where the matter has been under investigation for several years.

It has been shown that the amount of normal chlorine decreases regularly from the sea-coast inland. Waters, free from all contamination, near the coast contain about 0.65 part of chlorine to 100,000, and in the western part of the State about 0.10 part to 100,000.

Lines, called "isochlors," have been plotted, passing through places of equal amount of chlorine in normal waters, and as these preserve a general parallelism to the coast-line, it is reasonable to attribute the decrease of normal chlorine to the diminishing effect of the sea-air. From recent investigations it is probable that a similar set of lines can be found for New Jersey and Eastern Pennsylvania. In the present paper the vicinity of Philadelphia, east of the Delaware River, is alone under consideration. Ten suitable sources of water were found, from which 21 samples were taken and analysed. It is probable from these that the normal chlorine of this district approximates closely to 0.20 part to 100,000. The chlorine was determined by the usual volumetric method with silver nitrate and potassium chromate, but with the improvements and corrections described by Hazen (Am. Chem. J. 11, 409), which are re-described.—R. B. P.

#### PATENTS.

##### *Improvements in or relating to the Manufacture or Preservation of Condensed Milk.* C. Ekin and W. H. Thew, both of London. Eng. Pat. 14,894, August 3, 1893.

ACCORDING to this invention, levulose or maltose, or a mixture of both, is used instead of cane-sugar in the manufacture of condensed milk or condensed peptonised milk.

The inventors claim the preparation of a product which does not cause dyspepsia. In other respects the manufacture of the peptonised article is carried out as set forth in the specification of W. H. Thew, Eng. Pat. 1313 of 1884.

—L. de K.

##### *Improvement in the Manufacture of Condensed Milk Preparations.* H. B. Briggs, London. Eng. Pat. 15,434, August 14, 1893.

ACCORDING to this invention, levulose is substituted for cane-sugar in the manufacture of condensed milk, and used to the extent of about 25 per cent.

The inventor claims that thus a more soluble and easily digestible product is obtained.—L. de K.

##### *Improvement in the Manufacture of Condensed Milk Preparations, Invalids' and Children's Foods.* H. B. Briggs, London. Eng. Pat. 15,435, August 14, 1893.

ACCORDING to this invention, invert sugar is substituted for cane-sugar in the manufacture of condensed milk and farinaceous food preparations.

The inventor claims the preparation in this wise of articles of easier digestibility.—L. de K.

These results show that in the direct purification an effluent is obtained containing almost invariably a greater amount of organic matter in solution, as is the case when the purification has been preceded by filtration. This shows that lime to some extent does dissolve suspended organic matter, but the statement that by the lime treatment the total quantity of organic matter in solution is increased, is without foundation.—C. O. W.

*The Removal of Pathogenic Bacteria from Drinking-Water by Sand-Filtration.* G. W. Fuller. Tech. Quart. 1893, 6 [4], 273—285.

THAT sand-filters properly worked are effective in removing bacteria from drinking-water is shown by the investigations

of P. Frankland, who found an average removal of 97.6 per cent. of the bacteria in unfiltered Thames water, after filtration. At the experiment station at Lawrence, Massachusetts, intermittent filtration through sand was found to effect the removal of 97.3 per cent. of the bacteria in the original water taken from the city supply. When river-water containing more than ten times as many bacteria as did the city supply, was filtered experimentally in the same manner, a filtrate containing as low a number of bacteria as in the former experiment was obtained. Three of the species of bacteria most prominent in the river-water were not present in the filtered water, *B. coli communis* being one of these. That the water was not always completely sterile appears to be due to the fact that bacteria found access to it after its filtration, through

the outlet-pipes and under-drains. Intermittent filtration, according to the method thus experimentally employed, would be too costly for practical purposes, as the amount of water filtered per acre did not exceed 250,000 gallons daily.

An elaborate series of experiments was carried out to ascertain whether ordinary sand-filters carefully worked were competent to remove bacteria applied in large numbers as pure cultivations. An example of the method of experiment ultimately adopted, may be quoted. A pure cultivation of a bacterium was prepared of such strength that 1 cc. contained on an average 20,000,000 bacteria. This solution was applied to the filters in the proportion of one part to 3,000 parts of water at intervals of one or two hours, according to the rate of filtration. Every cubic centimetre of water which entered the filter contained on an average 6,000 bacteria in addition to the water-bacteria normally present. The amount of organic matter in the water was increased as little as possible, so that direct comparison could be made with the water in its un inoculated condition. Using *B. prodigiosus* for the purposes of this investigation, the following results were obtained:—

Depth of Filter in Feet.	Rate of Filtration (Galls. per Acre daily).	Average Number of Bacteria applied.	Per Cent. removed.
5	1,300,000	3,000	99.81
5	2,400,000	6,220	99.96
2	1,800,000	1,700	99.86
1	1,000,000	6,230	99.83

With regard to the efficiency of the surface layer of a filter (considered in Berlin to be the most important portion) it is found that the number of bacteria in the filtered water is but slightly influenced by the removal of the surface layer during the scrapings of the filter which are periodically necessary to prevent choking. There is certainly a slight increase in the number of bacteria in the filtered water after scraping, but it only amounts to a small fraction of 1 per cent.

Practice differs concerning the selection of sand for the construction of filters. In Germany it is usual to wash out the finer particles, but this is not done at the Lawrence experiment station now under consideration. Samuelson, the chief engineer of the Hamburg Waterworks, states that the best filtering sand is one consisting of particles uniformly approximating to a diameter of 1 mm. Experience at Lawrence shows however, that finer particles than this are useful in filling up interstices, and the following canon has been arrived at:—"The effective size of a sand is considered as the maximum diameter of the finest 10 per cent. of the grains." The size of the sand grains from the best filters at Lawrence lies between 0.2 and 0.3 mm. That it is the upper part of the filter which does the greater part of the work of purification, is shown by the following table, containing the figures given by a filter that had been in operation for about 6 months.

Depth from Surface (in inches).	Bacteria per Grain of Sand.
0-1	1,100,000
1	320,000
1	110,000
2	21,000
4	4,000
6	1,600

As a practical outcome of the experiments carried out at Lawrence, a filter  $2\frac{1}{2}$  acres in area, and having a capacity of 5 million gallons per day has been constructed, which is remarkable from the fact that it is worked intermittently,

the oxidation thus induced aiding the removal of the organic matter, which accumulates at the surface of the sand. It has also been demonstrated that it is practicable to construct filters which will economically remove 99 per cent. of the bacteria in the unfiltered water.—B. R.

## PATENTS.

*Improvements in the Treatment of Sewage or Analogous Foul Waters or Matters for Effecting the Disinfection and Purification thereof.* A. P. Hope, Leicester. Eng. Pat. 10,458, May 27, 1893.

Air or oxygen, together with anti-septics or deodorisers such as creosote, cresolite, carbolic emulsion, is injected into the sewage by means of steam. After this treatment, the sewage may be treated by any precipitation process.

—J. C. C.

*Improvements relating to the Purification of Water, and Apparatus therefor.* L. and C. Maiche, Bois Colombes, France. Eng. Pat. 12,941, July 1, 1893.

THE inventors lay claim to a process for sterilising water which consists in destroying the germs and microbes by the employment of lime, then rendering the water drinkable by precipitating the lime with carbonic acid. An apparatus for mixing the lime water and water to be purified, is also described and claimed.—J. C. C.

*Improvements in the Purification of Sewage and other like Waste Liquids, and in Apparatus employed therefor.* W. E. Adeney, Monkstown, co. Dublin, and W. R. Parry, Kingstown, co. Dublin. Eng. Pat. 13,154, July 5, 1893.

THE patentees here extend and improve upon their previous inventions, see patents 3312 and 18,983 of 1890, and 10,929 of 1891 (this Journal 1891, 1021 and 1892, 630). They now treat the effluent of settled sewage, successively, with sodium manganate (2—5 grains to the 1 gallon), aluminium sulphate (about 7 grains to the gallon), and sodium nitrate (2 to 3 grains to the gallon), the effluent being then subjected to the action of bacteria and other micro-organisms.

The plant employed is quadruplicate, each unit comprising (1) a deep tank, narrowing at the bottom to (2) an axially located sump hole, to the bottom of which reaches (3) a pipe connected with (4) a chamber in which a partial vacuum can be produced. The foregoing arrangement permits of the collection, in the respective four chambers, of the solid sewage, of the three precipitates produced by the three reagents employed, and of the deposit produced by the bacterial action. Near the top of each tank is (5) an overflow, leading to (6) a wide pipe which in its turn extends nearly to the bottom of the next tank; this allows of the flow of liquid from the first to the second tank, from the second to the third, and so on, the reagents enter the stream in the conduit between two tanks. An equal distribution of the upward flow of liquor in the tanks is secured by means of spreading arms or plates placed horizontally near the end of the affluent pipe.

The products obtained are (from tank No. 1) 1. solid sewage settlings, which are drained and dried, being sometimes mixed with a little manganese oxyhydrate to prevent putrefaction during the process; 2 (from tank No. 2), manganese oxyhydrate which is dried and used in sodium manganate manufacture; 3 (from tank No. 3), aluminium hydrate and basic sulphate, which is recovered as sulphate by treatment with sulphuric acid. This precipitate gradually gets richer in manganese (carried over from tank 2) and is then fused with sodium hydrate and nitrate to obtain sodium manganate and aluminate.

The authors have further found that the sulphates of iron and manganese, as obtained by treating manganiferous iron ore with sulphuric acid, may be substituted for sulphate of alumina in tank 3 and the precipitated basic hydrates and carbonates recovered by subsequent treatment with sulphuric acid.

When sewage contains much or very carbonaceous organic matter, it is well to add the aluminium sulphate (or its iron and manganese equivalent) before the sodium manganate, increasing its amount to 10–20 grains per gallon. Waters containing much acid or alkaline trade effluent require to be preliminarily neutralised by chalk or by mineral acid, according to circumstances.

A further claim in this patent relates to an automatic machine for supplying regularly definite amounts of reagent, whether liquid or solid.—E. R. B.

*Improvements in the Treatment of Sewage Sludge.* R. C. Tanner, Chester. Eng. Pat. 13,305, July 8, 1893.

THESE improvements consist in breaking up pressed sludge cakes in a pug mill, to the under side of which is attached a perforated cone, through which, by the rotation of a conical screw, the material is forced to fall down in a vermicular condition on to a travelling belt which carries it into a hot chamber, where it is dried and is fit for immediate use as a manure, or for carbonisation to obtain ammoniacal liquor and other by-products.

The machinery which the inventor proposes to employ is described in Eng. Pat. 2218, 1859.—J. C. C.

*Improvements in the Treatment of Sewage and other Foul Waters.* R. C. Tanner, Chester. Eng. Pat. 14,642, July 31, 1893.

A SOLUTION of persulphates of iron or a mixture of proto- and persulphates of iron is evaporated to dryness and mixed with bleaching powder. The sewage is treated with this mixture after having been made alkaline with lime.

—J. C. C.

*Improvements in the Construction of Tanks or Receptacles for the Precipitation of Sewage, and for like Purposes.* E. C. Ives, Derby. Eng. Pat. 13,411, July 11, 1893.

IN the figure, A is the tank, terminating at its lower extremity in an inverted cone, with or without the sump B. C is the sludge suction-pipe. The sewage enters the tank through the pipe F, directly over the sump B (finally flowing

TANK FOR THE PRECIPITATION OF SEWAGE, &c.

upwards, by means of the cover G, which is connected to distributing arms H, designed to distribute the sewage over the whole surface of the tank when running into the same, and to ensure the rising of this sewage uniformly to the overflow arms at I. At or about the top are overflow arms at I, spread out to assist the uniform upward action of the sewage, the overflow arms being connected with an outlet K to carry the effluent away.—J. C. C.

*Improvements in and in the Production of Compositions adapted to be used in the Treatment of Sewage and other Foul Waters.* C. A. Burghardt, Manchester. Eng. Pat. 14,801, August 2, 1893.

THE patentee produces a new composition or cake containing ferric sulphate, ferric chloride, aluminium sulphate, and, in some cases, sodium sulphate, for the treatment of sewage and other foul waters. The new product principally differs from that claimed in his patent, Eng. Pat. 13,316 of 1892 (this Journal, 1893, 778), by the presence in it of aluminium sulphate and by the fact that no storing process is now necessary.

Two methods of preparation are described: either finely-powdered bauxite, or other aluminiferous material, ferric oxide, and salt are mixed with sulphuric acid, or to an aqueous solution of aluminium sulphate concentrated solution of ferric chloride, mixed with sodium sulphate, is added. In either case evaporation yields the mass or cake claimed.

Whether the aluminium or the iron is allowed to predominate in the cake is determined by the special purpose to which it is to be put: for "general domestic sewage" the cake should contain about 11 per cent. of iron as ferric sulphate or chloride, and 2.5 per cent. of aluminium as sulphate.—E. R. B.

*Improvements in and Relating to the Softening and Purifying of Water and Apparatus therefor.* H. L. Doulton and A. W. Manger, both of Lambeth Potteries, Surrey. Eng. Pat. 15,169, August 8, 1893.

THE apparatus is intended to soften and purify water by firstly, removing the temporary hardness; secondly, removing the permanent hardness; and thirdly, for removing the alkalinity when required. To remove the temporary hardness the water is treated with lime in a mixing trough and afterwards passed through settling and filtering tanks. To eliminate the permanent hardness the water is then treated with soda or other suitable reagents, in a similar set of tanks, and finally, to remove alkalinity a perforated tank containing suitable reagents, such as boracic acid, aluminium phosphate, or the like, is arranged between the baffles of the settling tanks in such a manner that the water is subjected to the action of such anti-alkaline reagents as are adopted.—E. G. C.

*Improvements in the Treatment of Sewage and Waste Waters.* G. Jarman, Huddersfield. Eng. Pat. 16,522, September 2, 1893.

THE inventor treats charged sewage sludge, the result of precipitation, with crude hydrochloric acid to dissolve out the iron or other mineral matter contained in the sludge. This solution, after being partially neutralised, can be used again as a precipitant for other sewage. The animal charcoal after the extraction is used as a filtering medium.

—J. C. C.

*Improvements in or Relating to the Disinfection of House and other Refuse, and Apparatus therefor.* A. T. Boulton, Middlesex. From F. S. Salberg, Brussels, and M. Neumaun, Vienna. Eng. Pat. 4169, February 27, 1894.

IN this patent is described a general process, automatic in its action, for the disinfecting and rendering harmless or refuse and offal of all kinds, at the time of their being deposited in all the various kinds of receptacles allotted to their storage. The several modifications of these receptacles (dust bins, scavengers' carts, water-closets, with and without water supply, urinals, lavatories, &c.) rendered necessary by the process are also described, figured, and claimed at considerable length.

The "fundamental idea" of the process "consists in the utilisation of the force developed, for instance, by the discharge into a scavenger's cart of refuse from a bin, for working an apparatus intercepting the dust on the one hand, and on the other distributing a disinfectant."

In a modification which is generally applicable, refuse falling into a receptacle loads the vanes of a shaft disposed across the cavity of the receptacle, the shaft then rotates, and by a simple mechanism allows a certain quantity of a disinfectant to fall into the receptacle. Either solid or liquid disinfectants may be employed.—E. R. B.

### (C.)—DISINFECTANTS.

#### PATENTS.

*Improvements in Fumigants.* I. S. McDougall and J. T. McDougall, London. Eng. Pat. 14,411, July 26, 1893.

To facilitate the combustion of sulphur and of carbon, when either of these substances is burned as a fumigant, the inventors propose to add suitable nitrates, such as those of potassium, sodium, ammonium, or barium, in proportions, however, not so high as to cause explosions. In practice, they find "sulphur, 75 parts; nitrate of potassium or other nitrate or mixtures of them, 25 parts"; and "carbon, 70 parts; nitrates, 30 parts"; to be useful proportions. The percentage of nitrate must not exceed 60 per cent. according to the inventors.—E. R. B.

*Improvements in the Production of Insecticides.* I. S. McDougall and J. T. McDougall, London. Eng. Pat. 14,412, July 26, 1893.

In the preparations, by means of boiling water, of tobacco extract, to be used as an insecticide, hitherto much of the nicotine has been lost by volatilisation; the patentees therefore propose to extract with very dilute acid, e.g., with 16 oz. of concentrated sulphuric acid to 100 lb. of tobacco. The acid employed may be sulphuric, hydrochloric, nitric, acetic, phosphoric, or a suitable mixture of them.—E. R. B.

*A New Method of Treating Cotton Wool, Lint, Gauze, Wood Fibre, Lint, Bandages, Flannel, Sponges, and similar Substances used for Medical and Surgical Purposes, in order to render them Antiseptic.* M. C. Clutterbuck, Barton-on-Trent. Eng. Pat. 14,812, August 2, 1893.

The substance to be treated is placed in a chamber and alternately subjected to the action of sulphur dioxide gas and ammonia, or a mixture may be introduced by volatilising ammonium sulphite. The process is completed by driving out the excess of ammonia, if any, by a current of dry air.

—J. C. C.

*Improvements in Sulphur Candles or Fumigators.* C. T. Kingzett, Chislehurst, Kent. Eng. Pat. 14,903, August 3, 1893.

The object of this invention is to provide a means whereby the block of sulphur, forming a "sulphur candle" or fumigator, may be readily ignited. This "lighter" is made by steeping any open or porous material (such as muslin, cotton wool, paper, straws, &c.) in melted sulphur so that it becomes coated with it. Combustible material is naturally preferable for the supporting material, but thin asbestos cloth for example may be employed, providing the coating layer of sulphur be sufficiently thin.

To use the "lighters" these may be either wrapped round the top of the candle projecting above the end, or the strip may be fused on, or simply lie loosely on the top of the candle.

In any case the thin layer of sulphur on the "lighter" is readily set on fire, and running down on to the top surface of the candle, fires it also.

The lighting material may itself be used as a fumigator, and is then conveniently made in a ribbon like form which can be rolled up as a candle.—E. R. B.

*Improved Method and Means for Preserving Food and other Substances and for supplying Sterilised Air to Rooms and other Enclosed Spaces.* J. Eilfont, Brussels, Belgium. Eng. Pat. 15,757, August 19, 1893.

The principle recognised in the process is that a layer of air passing over a moist surface will leave on this surface all the microbes and bacteria it contains, so that if the place where air is admitted into a suitably closed vessel be provided with an apparatus forcing such air to circulate over hygroscopic surfaces, or zig-zags, before it obtains access to the vessel, the latter will only contain absolutely sterile air, not altering the food or other substances stored or placed in this vessel. It is proposed to mix with the water or liquids used for moistening the hygroscopic or moist surfaces or zig-zags,—hydrofluoric acid or fluorides, or other antiseptics.

—L. de K.

*New or Improved Sanitary Paper, Felt, or Analogous Material.* S. Guillian, Liverpool. Eng. Pat. 15,914, August 23, 1893.

See under XIX., page 834.

*Scab Wash or Medicinal Lotion for the Cure of Scab in Sheep.* A. Robertson, Oban, N.B. Eng. Pat. 3500, February 19, 1894.

This is a paste which when mixed with water forms a medicinal lotion. The following are the constituents of the paste.

Arsenious acid, 320 grains; sulphur, 540 grains; tar distillate (25 per cent.), 1 oz. 5 drams; carbolic acid (95 per cent.), 6 drams; water, 5 drams; caustic soda, 184 grains; wool fat, 240 grains; resin, 220 grains. The fat having been partially saponified by heating with part of the soda and water, the remainder of the soda and water together with the arsenious acid previously dissolved in the solution of soda, is added while all are still hot, and the other ingredients stirred in.—J. C. C.

*Improvements in Insecticides.* A. J. Boulton, London. From F. Haase, Dresden, Saxony. Eng. Pat. 10,188, May 25, 1894.

Two parts of finely ground quassia-wood are mixed intimately with one part of sugar; the mixture is then triturated with a slight addition of some suitable substance, which will tempt insects from some distance, and at the same time conceal the matter contained in the quassia-wood which repels them; such substances being valerician or butyric acids, &c. The mixture is then ground with a solution of gum-tragacanth and made into tablets, pastilles, &c.—J. C. C.

## XIX.—PAPER, PASTEBOARD, Etc.

*Nitrocellulose in Filter-Paper.* E. Cramer. Zeits. angew. Chem. 1894, 269.

The incineration of filter-papers is a tedious operation which may be obviated when employing papers consisting wholly or partially of nitrocellulose. Such papers offer the additional advantage of filtering very rapidly, and of not being quite as hygroscopic as ordinary filter-papers.

—H. A.

## PATENTS.

*Process for Utilising the Lyes of Sulphite Cellulose Products Obtained in such Process, and Apparatus Employed for that Purpose.* A. Mitscherlich, Friburg, Germany. Eng. Pat. 12,927, July 1, 1893.

THE inventor claims a separation of the constituents of the lye of sulphite cellulose by osmose in a special apparatus, and utilises such constituents for a tanning material and a cementitious material. He also obtains alcohol by fermenting a certain portion of the liquor, and further obtains a food for animals.—J. C. C.

*New or Improved Sanitary Paper, Felt, or Analogous Material.* S. Quilliam, Liverpool. Eng. Pat. 15,914, August 23, 1892.

A FELTED paper is produced by any ordinary process out of wool, wool and cotton, or sponge. When made, or nearly made, it is perforated, and then thoroughly indurated with a disinfectant, such as "Izal," carbolic acid, and the like.

—J. C. C.

*Improvements relating to the Treatment of Paper for Receiving Printed Impressions.* P. M. Berger, R. Waldbaur, and E. F. Worlitzer, Leipzig-Schönefeld, Germany. Eng. Pat. 16,358, August 30, 1893.

IN this process barium sulphate, hydrate of alumina, or calcium sulphate, are precipitated in the paper itself, and it is claimed that paper treated in this way is particularly suited for block printing, as it takes the ink equally all over.—J. C. C.

*Method of Bleaching Paper Pulp or other Flocky Substances.* J. W. Abom, Stockholm. Eng. Pat. 8964, May 5, 1891.

THE material to be bleached is placed in a receptacle of wood, stone, or other non-conducting material which is not acted on by chlorine, and which is provided with a stirring device. A chloride solution, preferably of an alkali or an alkaline earth, is poured into the receptacle, and an electric current is made to traverse it, preferably so that one pole will be at the circumference of the vessel and the other near the centre. The poles consist of carbon plates. When the current has been in action for 20 or 40 minutes the contents of the receptacle are discharged into another suitable vessel where the after bleaching is carried on during 10 to 20 hours. During the bleaching operation the temperature must not rise to 60° C., or the hypochlorite formed by the current will be transformed into chlorate which is inert as a bleaching agent.—J. H. C.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Sodium Boro-Salicylate.* P. Adam. Bull. Soc. Chim. 1894, 11, 204.

BOSE and Schwartz have demonstrated that addition of borax increases the solubility of salicylic acid. Such compound solutions have been recommended by various authors. However, the question whether these solutions contain a compound of borax and salicylic acid has never been investigated, although the existence of tartroborates renders such an assumption very probable. It was found that by boiling 62 grms. (1 mol.) of boric acid with 160 grms. (1 mol.) of sodium salicylate in 350 cc. of water, a syrupy liquid was obtained. If boric acid is used in excess the excess separates out on cooling. The mixture, in the above proportions, of boric acid and sodium salicylate, reddens litmus and

turns turmeric paper brown, but the syrupy solution obtained on boiling the mixture has no action on these indicators. On evaporating this solution white opaque masses of sodium boro-salicylate are obtained. This substance is very easily soluble in water, and the solutions produce no precipitate with the ordinary reagents for boric acid.—C. O. W.

*The Constitution of the Mercurial Compound of Thymol Acetate.* Arch. Pharm. 231, 123.

THE compound possesses the formula—

The substance contains 55 per cent. of mercury.

—C. O. W.

*Oil (Otto) of Roses.* J. Bertram and E. Gildermeister. J. prakt. Chem. [2], 49, 185—196.

ECKART showed (this Journal, 1892, 265) that the chief constituent of the so-called "otto of roses" is an alcohol,  $C_{10}H_{18}O$ , to which he assigned the name rhodinol. Markownikoff and Reformatzky (this Journal, 1894, 272) believe that rhodinol has the formula  $C_{10}H_{20}O$ ; Barbier, however (Comptes rend. 117, 177), confirms Eckart's formula.

The present authors were induced to make the following experiments on account of the statement of Monnet and Barbier (this Journal, 1894, 658) that Oil of Pelargoniums contains a considerable quantity of rhodinol. They have therefore treated the various geranium oils of commerce with alcoholic potash, and, after driving over the oil with steam, fractionally distilled it *in vacuo*. In no case was a compound isolated having the properties of Eckart's rhodinol, but the fractions which are said to contain rhodinol consist chiefly of geraniol.

The authors draw attention to the conflicting statements regarding the physical properties of rhodinol. They have isolated Geraniol from Bulgarian and German oil of roses by means of its compound with chloride of calcium (Jacobson, Annalen, 157, 231), from "palmrosa oil" (*Andropogon Schoenanthus* L.), African geranium oil, and citronella oil. They confirm Bouchardat's observation that Barbier's licanthol from linalool is identical with geraniol. The difference in specific gravity of the geraniol from various sources (0.8834—0.8801) may possibly be attributed to the ready oxidisibility of the compound when exposed to the air.

The chief constituent of rhodinol, and consequently also of otto of roses, may therefore be regarded as geraniol, but the nature of the minute impurity which imparts the perfume of roses to the geraniol is unknown.

In opposition to the views of Markownikoff and Reformatzky (*loc. cit.*), the authors consider that the stearoptene of otto of roses is a mixture of hydrocarbons.—A. R. L.

*Champacol.* E. Merck. Arch. Pharm. 231, 123.

CHAMPACA-wood contains an aromatic substance which is obtained by distillation with steam. It is a new camphor of the formula  $C_{17}H_{26}O$ , which, when recrystallised from dilute alcohol, melts at from 86 to 88° C. It forms white needles soluble in alcohol and ether, less soluble in water. The pure substance is odourless and can be sublimed.

—C. O. W.

*The Preparation of Pure Digitonine.* H. Kiliani. Arch. der Pharm. 231, 460.

DIGITONINE crystallises from 85 per cent. alcohol with the composition  $C_{57}H_{100}O_{13}$ , 511.0. To obtain large prisms, it is necessary to keep the saturated solution at 45° for about eight hours; at lower temperatures, minute lamellae are obtained, and these are less pure.—E. R. B.

*Note on the Preparation of Free Hydroxylamine.* J. W. Bruhl. Ber. 27, 1347.

The author, in opposition to Lobry de Bruyn, states that he can prepare several hundred grms. of free hydroxylamine at one operation, by means of his vacuum fractionating apparatus. (This Journal, 1893, 1054. *Oximides*.)—J. W.

*The Investigation of Saccharin.* R. Hefelmann. Pharm. Central H. 1894, 105.

1. *Para-Acid Determination.*—10 grms. of saccharin and 100 cc. of sulphuric acid of 1.31 Tw. are immersed for three hours in a briskly boiling water-bath, with occasional agitation. The decomposition is completed when a drop, on considerable dilution with water, is free from a sweet taste. The acid solution is diluted with an equal volume of water, allowed to cool, and let stand over night. No precipitate will be formed under these conditions from pure saccharin, but in the presence of the para-acid the whole of it separates out on standing for 12 hours up to three days, or on addition of a small crystal of the substance. The precipitate is filtered off, washed with a little water, and transferred from the parchmented filter-paper into a beaker and from this on to a fresh filter-paper for freeing it from all the sulphuric acid. It is dried at 100°, separated from the filter, and weighed. The para-acid ought not to taste sweet, but acid; no sulphuric acid reaction ought, however, to be obtained. Its melting-point is between 270°–280°. The washing and weighing of the precipitate may be performed in a Gooch crucible.

2. *Saccharin - Nitrogen Determination.*—The filtrate from the para-acid is made up to 500 cc., 50 cc., equal to 1 gm., are supersaturated with caustic magnesia, and the ammonia distilled off without cooling, into 20 cc. of half-normal sulphuric acid, titrating back with one quarter normal caustic potash, using methyl-orange or rosolic acid as indicator. The acid consumed is equivalent to the nitrogen decomposed. One hundred per cent. saccharin contains 7.67 per cent. of nitrogen. One per cent. of nitrogen corresponds to 13.04 per cent. of saccharin.

3. *Determination of the Total Nitrogen according to Kjeldahl.*—One gm. of saccharin is weighed off into a thin-walled vessel and introduced into Kjeldahl's decomposing flask, where it is boiled for 2 hours with 25 cc. of concentrated sulphuric acid and 0.5 gm. of mercury. On cooling, the solution is diluted with water, introduced into a flask of 1 litre capacity, and further diluted to about 250 cc. Excess of potassium or sodium hydrate is now added along with 3 grms. of well-washed zinc-dust free from nitrogen (or, if desired, excess of potassium sulphide solution), and the ammonia distilled off by boiling for one hour as described under 2).

Commercial saccharins are sufficiently characterised when proceeding as under 2 and 3, and a gravimetric para-acid determination is thus obviated. As an illustration the following results were obtained:—

	Saccharins, 300 times sweeter than Sugar.	
	Heyden.	Fahlberg.
Moisture .....	0.28	0.23
Ash, without addition of sulphuric acid.	0.82	0.50
Dried substance, less ash .....	98.92	99.47
Benzoyl- <i>p</i> -sulphonic imide .....	32.47	36.37
Nitrogen of the filtrate from the <i>p</i> -acid.	5.19	1.06
Total nitrogen.....	7.37	7.15
Saccharin, calculated from the nitrogen of the filtrate from the <i>p</i> -acid.	67.66	69.75

—H. A.

*Coniine and its Compounds.* J. Schorm. Zeits. angew. Chem. 1894, 266–267.

When treating henlock seed with sodium carbonate solution and distilling with superheated steam, the base is found in the distillate, partly as the carbonate, soluble in water. This circumstance may be made use of for producing the pure base. To this end the distillate is neutralised with hydrochloric acid, the aqueous solution boiled down, and any oily impurities present decomposed by prolonged heating on a sand-bath until the residue is odourless. On dissolving in water and filtering, a clear solution ought to be obtained, but if tinged, it may be purified by treatment of the cold neutral solution with commercial 3 per cent. hydrogen peroxide solution. Beautiful and clear coniine crystals are formed on boiling down the solution, and further crops may be obtained by repeated evaporation. The final mother-liquor contains conhydrine and a new base, which may be separated by dilution with water, rendering slightly alkaline with caustic soda, and shaking with ether, which dissolves conhydrine, leaving the new base in the residue.

For the preparation of its salts an aqueous solution of coniine forms the starting-point. Such a solution may be produced from coniine chloride by dissolving in five parts of water, treating with potassium carbonate as long as turbidity is produced, pouring off the clear liquor from the potassium chloride, and distilling. The aqueous distillate is a 10 per cent. coniine solution, and floating on this is the pure base in the form of the hydrate. The specific gravity of the latter is 0.9 at 12 C., and on heating above 100° 20 per cent. of water separates out, and anhydrous coniine remains. This distils at 168° (760 mm.), and has a specific gravity of 0.87.

Purification with hydrogen peroxide, as described, may be made use of with advantage for obtaining other alkaloids. —H. A.

*Mercuric Phenolates and Certain of their Derivatives.* E. Desesquelle. Bull. Soc. Chim. 11, 1894, 263–269.

*Naphthol compounds.*—By the action of mercuric chloride on potassium  $\beta$ -naphthol in aqueous solution, a compound has been prepared answering to the formula  $\text{HgCl}(\text{OC}_{10}\text{H}_7)$ . This substance, which may be called mixed chloride and naphtholate of mercury, and for which the author suggests also the name  $\beta$ -sublimo-naphthol, is soluble in alcohol, but very slightly soluble in water. Its alcoholic solution on cooling deposits colourless prismatic crystals, which, after a time, become coloured.

On pouring a solution of mercuric chloride (1 mol.) into an aqueous solution of potassium- or sodium- $\beta$ -naphthol (2 mols.)  $\beta$ -naphtholate of mercury is precipitated. The precipitate, at first yellowish-white, becomes colourless after 24 hours. The compound is insoluble in the ordinary solvents, but soluble in phenol or in a boiling solution of phenol. Its formula is  $\text{Hg}(\text{OC}_{10}\text{H}_7)_2$ . It is attacked by acetic acid with the formation of a mixed acetate and  $\beta$ -naphtholate  $\text{HgOOC}_2\text{H}_5(\text{OC}_{10}\text{H}_7)$ , consisting of colourless crystals, soluble in alcohol, but very slightly soluble in water.

*Phenol compounds.*—The corresponding phenol compounds are not prepared with the same ease. The mercuric phenols hitherto prepared are amorphous precipitates consisting of mixtures of several substances and of various colours. Many such are sold the composition of which does not in the least correspond with the formula on the label.

The precipitate obtained on pouring potassium phenol (1 mol.) into mercuric chloride (1 mol.) is brick red, and contains chlorine; it answers to no definite formula. If the solutions are heated before adding them together, the brick-red precipitate becomes colourless after standing for 48 hours. On purification, by crystallising from alcohol, it is obtained in the form of colourless crystals, which melt with decomposition at 210 C.; the crystals are soluble in phenol and possess the formula  $\text{HgCl}(\text{OC}_6\text{H}_5)$ . This may be called mixed chloride and phenolate of mercury or sublimo phenol.

If, at a low temperature, a solution of mercuric chloride (1 mol.) be poured into an aqueous solution of potassium

phenol (2 mols.), the white precipitate so formed contains 64.12 per cent. of mercury and 9.62 per cent. of chlorine. With 4 mols. of potassium phenol the precipitate contains 59.57 per cent. of mercury and 3.42 per cent. of chlorine.

If mercuric chloride solution is poured into potassium phenol until the precipitate which at first redissolves becomes persistent, it is found that at this moment one molecule of mercuric chloride has been used for eight of the phenol. On filtering, the filtrate deposits on cooling faintly pink crystals, which on recrystallising from phenol are colourless, and answer to the formula  $\text{HgO} \cdot \text{OC}_6\text{H}_5(\text{OC}_6\text{H}_5)_3$ , that is, they consist of hydroxyphenolate of mercury. This product may be also obtained, but in a coloured form, by the action of 1 mol. of mercuric chloride on 4 mols. of potassium phenol at the boiling temperature.

Acetic acid acts on the hydroxyphenolate so as to yield a mixed acetate and phenolate,  $\text{HgO} \cdot \text{OC}_2\text{H}_3(\text{OC}_6\text{H}_5)_3$ , consisting of colourless prismatic crystals, very slightly soluble in water or alcohol, fusible with decomposition at an elevated temperature.

Up to the present it has not been found possible by the above methods to prepare the phenolate of the formula  $\text{Hg}(\text{OC}_6\text{H}_5)_2$ .—R. B. B.

*The Alkaloids of the Papaveraceæ.* C. and G. Kænig and W. Tietz. Arch. d. Pharm. **231**, 136—184.

A. ALKALOIDS CONTAINED IN THE ROOT OF *Sanguinaria Canadensis*.—

(1.) *Chelerythrine*,  $\text{C}_{21}\text{H}_{17}\text{NO}_4 + \text{C}_2\text{H}_6\text{O}$ , exists also in the root of *Chelidonium majus* and of *Glaucium luteum*. It crystallises in small rhombohedra, which melt at 203° C., is soluble in chloroform, with a blue fluorescence, but less soluble in alcohol. Acids colour it an intense yellow; ammonia reprecipitates the white base. With Erdmann's reagent, a yellow coloration; with Fröhde's reagent, yellow colour becoming dirty green; with vanadyl-sulphuric acid, a red-violet colour. This alkaloid contains two methoxy-groups, and its formula may be written—

It forms a crystalline hydrochloride and other salts.

(2.) *Sanguinarine*,  $\text{C}_{20}\text{H}_{15}\text{NO}_4 + \text{H}_2\text{O}$ .—Crystalline needles, melting at 213° C., soluble in chloroform, alcohol, and acetone. Its solutions exhibit violet fluorescence, and its salts are blood red. The base itself acquires a pink colour when exposed to air. With sulphuric acid, yellowish-red colour; nitric acid, brownish; Erdmann's reagent, orange becoming scarlet; Fröhde's reagent, earmine-red becoming dirty brown; vanadyl-sulphuric acid, dark green becoming violet, and finally brown. Its formula is—

It forms crystalline salts.

(3.) *γ-Homochelidonine*,  $\text{C}_{21}\text{H}_{17}\text{NO}_3$ , is identical with the *β*-homochelidonine extracted by Selle from *Chelidonium majus*. Crystallises in small needles or in large plates, which melt at 169° C. Sulphuric acid gives a violet coloration becoming brownish-yellow; nitric acid, a yellow; Erdmann's reagent, light yellow, then violet, and finally yellow again; Fröhde's reagent, brown, passing to violet, blue, green, and yellow; vanadyl-sulphuric acid, violet becoming greenish-blue, and finally light brown. This alkaloid contains two methoxy-groups.

(4.) *β-Homochelidonine*,  $\text{C}_{21}\text{H}_{17}\text{NO}_3$ .—Crystalline needles melting at 159° C.

(5.) *Protopine*,  $\text{C}_{20}\text{H}_{15}\text{O}_3$ , is also found in the roots of *Chelidonium majus*, *maclaya cordata*, and *escholtzia californica*. It crystallises in two forms: from chloroform, in glassy crystals; from ether or acetone, in fine needles. Both forms melt at 207° C., and are insoluble in water. Coloration with sulphuric acid violet, becoming dirty green; nitric acid, yellow; Erdmann's reagent, in turn yellow, violet, green, and yellow; Fröhde's reagent, bluish-green; vanadyl-sulphuric acid, red violet, passing to dark blue.

B. THE PROTOPINE OF *Chelidonium majus*.—This only differs from that just described in a few minute details.

C. THE CHELERYTHRINE OF *Chelidonium majus* differs only from the chelerythrine of *Sanguinaria* in forming salts which are bright yellow in colour instead of orange.

To extract this Chelerythrine, the root is pulverised and then exhausted with boiling alcohol of 96 per cent., after having first separated the other alkaloids. The filtered liquid, after treatment with hydrochloric acid, on standing, deposits a mass of brilliant needles, more or less coloured, and mixed with short prisms—indeed, a mixture of hydrochlorides. These are decomposed by ammonia. The bases dissolve in alcohol and chloroform, and there subsequently separate rose-tinted rhombohedra with a small quantity of white needles, melting at 206°, and very unstable in the air. Chelerythrine melts at 203°, and dissolves in acetic ether with blue fluorescence.—R. B. B.

## PATENTS.

*Improvements in or connected with the Production of Oxygen from Atmospheric Air, and Apparatus to be Employed therein.* Brin's Oxygen Co. and K. S. Murray, London. Eng. Pat. 14,918, August 3, 1893.

IN the manufacture of oxygen from an absorbent material under reduced pressure the oxygen begins to come off before the whole of the residual air has been removed from the retorts, &c., and thus the first portions of oxygen become contaminated with nitrogen and must be wasted. With the view of minimising this loss it is proposed, immediately pumping out is commenced, to connect the retorts, preferably at their lower ends, with the oxygen holder, thus admitting oxygen. It is claimed that this oxygen displaces the air and enables it to be drawn off with less loss of oxygen than is at present suffered. Automatic gear is described, which opens connection with the oxygen directly the retorts are put under vacuum and closes it again at such time (regulatable at will) as it is considered the air should have been withdrawn.—L. T. T.

*Manufacture of Caffeine Sulphonates.* O. Imray. From "The Farbwerke vormals Meister, Lucius, and Brüning," Hoechst-on-the-Main, Germany. Eng. Pat. 16,949, September 8, 1893.

A SALT of caffeine sulphonic acid results when bromo- or preferably chloro-caffeine is heated with a solution of a neutral sulphate. In practice 100 parts of chloro-caffeine and 75 parts of sodium sulphide (anhydrous) are dissolved in 1,000 parts of water and the solution heated, preferably, in a digester, to 150° C. for eight hours. On cooling the sulphonated salt separates out almost entirely. When purified sodium caffeine sulphonate forms a white powder, easily soluble in water, but insoluble in alcohol.—H. T. P.

*An Improved Iodine Liniment.* J. J. Anning, Leeds. Eng. Pat. 17,209, September 13, 1893.

A SOLUTION of iodine in oleic acid. It is claimed that it will not stain, and is readily absorbed by the skin.

—H. T. P.

*A New Improved Process for the Manufacture of Anhydro-ortho-sulphamine Benzoic Acid (Ortho-benzoic Sulphinide) or of its Salts from Commercial Saccharin.* A. R. Ling, Wimbledon. Eng. Pat. 21,417, November 10, 1893.

COMMERCIAL saccharin consists of a mixture of anhydro-ortho-sulphamine benzoic and para-sulphamine benzoic

acids. The new process for separating them is based on the fact that the ortho-acid readily decomposes the neutral salts of certain weak acids (acetic, citric, &c.), and passes into solution, whilst the para-acid is unaffected and remains undissolved. In practice, sodium acetate may be used at the rate of 1 part of acetate dissolved in 10 parts of water to 2 parts of 60 per cent. saccharin, the reaction being allowed to proceed in the cold, or assisted by heat. In either case the cold liquid is filtered from the insoluble para-acid. The filtrate contains the pure sodium salt of the ortho-acid, together with an equivalent amount of acetic acid. The latter may be recovered by distillation, and the ortho-acid finally isolated by any suitable method.

—H. T. P.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*The Annual Report (Eighteenth) of H. M. Inspectors of Explosives for 1893.*

In this report attention is called to the retirement of Col. Cundill from his position as inspector on account of ill-health. His place has been filled by Capt. J. H. Thomson, R.A.

The only modification made in the law during the year is the authorising of the packing of smokeless powders containing nitroglycerin in tin canisters, so as to put them on the same footing as powders composed essentially of nitro-cellulose.

The total number of factories licensed to manufacture explosives is now 127, one new factory having been licensed and three old ones having ceased to exist since the previous year. The inspectors say that "A more intimate acquaintance with the properties of nitro-cotton, which has been brought about in a large measure from its employment in the manufacture of the various smokeless powders, has brought to light the fact that its explosiveness does not depend, as hitherto supposed, on the degree of its insolubility. All nitro-cotton, however soluble, is now admitted to be 'explosive.' The question, therefore, whether collodion cotton, which is largely used for the manufacture of collodion, should be ranked as an explosive has again come under our consideration, and we have decided that for the present there is no necessity to bring it within the scope of the Act, so long as it is either in solution (in alcohol and ether) or wet, or saturated with methylated spirit and inclosed in air-tight cases, in any one of which states it is available for conversion into collodion." The amount of foreign nitroglycerin compounds suitable for blasting purposes imported during the year was 576,950 lb., being a large decrease on 1892, when the total was 850,000 lb.

Dr. Dupré, in his report to the inspectors, again calls attention to the liability to oxidation so often found in the samples of gelatin dynamite examined, and insists on the necessity of great care being used in this manufacture. Two new smokeless powders, "Westfalite," consisting of ammonium nitrate and gum lac, and "Von Forster's Powder," consisting of gelatinised nitrocellulose with a small proportion of chalk were favourably reported on, and a "Chlorate" powder, "Schnebelite," passed the preliminary tests and is still under examination. In consequence of an explosion caused by sodium peroxide a series of experiments was undertaken to ascertain how such an explosion could have originated. "These experiments clearly demonstrated that peroxide of sodium by itself is a perfectly stable body, not liable to spontaneous decomposition, and not liable to explode by percussion, friction, heat, or by the addition of water, although in the latter case much heat is evolved and steam produced. When, however, the peroxide is mixed with, or even simply in contact with any combustible substance, it becomes a highly dangerous material, inasmuch as, under these circumstances, the

access of water to the mixture causes the almost instantaneous outbreak of fire, or causes an explosion according to the greater or less intimacy of the mixture. The precautions suggested by this explosion, fortunately unattended with loss of life or serious damage to property, are obvious. Peroxide of sodium should always be packed in a strong metallic case not liable to injury during transport, and all contact, or possibility of contact, with any combustible matters carefully avoided." The number of deaths from accidents in factories is six, as against two in 1892; the average for the past ten years being 5.9.

Owing to the repeated accidents which have been caused by mixtures of potassium chlorate and sulphur, steps are being taken to prohibit the manufacture or use of fireworks containing these ingredients, except under approved conditions. The chief explosions which occurred at home and abroad are described and discussed. An interesting case is the burning without explosion of 4.212 lb. of gun-cotton at Waltham Abbey, and details gathered in regard to the terrible explosion of about 30 tons of dynamite at Sandaer show that structural damage did not extend beyond 650 yards, a distance only one-third of that which has to be kept clear as a proper safety zone round magazines containing comparable quantities of explosive under the Explosives Act.—W. M.

*The Inventor of Phosphorus Matches.* E. Jensch. Zeits. angew. Chem., 1894, 268-269.

RÖMER, Preschel, and Irinyi are variously named as inventors of phosphorus matches. From the testimony of a still living college friend, it appears that the real inventor is the Hungarian, János Irinyi. It was in 1835 when the latter, then 19 years old and a student at the Polytechnic School in Vienna, attended Professor Mössner's lectures on chemistry. He became greatly impressed by a demonstration of the reaction produced on rubbing together peroxide of lead and sulphur. It struck him straightway that the reaction may be greatly intensified when substituting phosphorus for sulphur. Irinyi was not to be seen at the college for the next few days. His friend wishing to see him called at his rooms but found the door locked, and on giving his name, received the unmistakable answer, "Geh' weg Schwab, ich mach' eine Erfindung." On joining his friends Irinyi had his pockets full of matches which he struck on the walls, all of them taking fire. He prepared them by melting phosphorus in a concentrated solution of glue, and shaking until the mass became cold and all the phosphorus assumed a finely divided state. This emulsion was mixed with brown peroxide of lead, and sticks previously dipped in molten sulphur, were immersed in the mixture. He sold his invention to a merchant named Römer for about 700*fl.* Irinyi is said to be still living in the south of Hungary.—H. A.

ERRATUM.—This Journal, July number, p. 730, col. 1, the abstract "An Improved Still or Retort," &c., should have appeared under XXIII., on page 761.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS, ETC.

*Apparatus for Fractional Distillation.* M. Otto. Bull. Soc. Chim. 1894, 11, 197.

The apparatus consists of a series of egg-shaped bulbs connected with each other on the top by wide tubes, and by narrow tubes on the bottom, in the manner shown in the diagram.

Experiments with mixtures of benzene and toluene, and methyl alcohol and acetone, show this apparatus to be vastly

superior to fractionating tubes of the well-known Le Bel-Henninger type.—C. O. W.

*The Prevention of Bumping in Boiling or Distilling Liquids.* V. Gernhardt, Ber. 27, 964–965.

In working out the method for determining the molecular weights of dissolved substances from the lowering of vapour pressure of their solutions, Beckmann introduced a boiling apparatus the function of which was to promote a steady ebullition in the liquid by disturbing the thermal equilibrium at one point by partial superheating, and thus preventing superheating throughout the whole mass of liquid. To attain this end Beckmann sealed a short piece of stout platinum wire through the bottom of the boiling-vessel. As platinum is a much better conductor of heat than glass, the liquid immediately surrounding the platinum wire becomes partially superheated, and a steady evolution of vapour bubbles takes place in the neighbourhood of the sealed-in wire. Vessels of this description, however, are very apt to crack, owing to the unequal expansion of platinum and glass. In a later form of the apparatus the platinum wire is sealed in by means of the red Jena enamel, and the vessel is thus capable of standing abrupt changes in temperature. Whilst using an apparatus of this kind the author noticed that the boiling took place, not from the platinum rod itself, but from the red enamel. Numerous experiments have shown that the expensive platinum may be replaced by the enamel alone, and a large number of such flasks made by Kachler and Martini, of Berlin, for the author, have given entire satisfaction.—J. S.

*Apparatus for Weighing out Liquids.* H. Schweitzer and E. Lungwitz. Chem. Zeit. 18, 529.

The weighing out of liquids which readily volatilise, of fats and oils, of tanning acids, &c., is a lengthy and inconvenient operation. The process is, however, much simplified by the use of the pipette shown in the figure. The exhaustion, which terminates in a capillary, which is bent within the bulb of the pipette towards the upper portions of its walls; the opposite side of the bulb is flattened in order that the pipette may be placed on the pan of the balance; the mouth-piece may be drawn out to a capillary, and the same applies

to the discharge-tube. A sufficient quantity of the liquid to be weighed is sucked up into the bulb so that the end of the capillary within the bulb projects beyond the surface of the liquid when the instrument is laid down on the flattened

Fig. 1.

Fig. 2.

portion. After wiping the end of the tube, the pipette and its contents are weighed; the necessary quantity of liquid is then run out, and the weight redetermined. For weighing solid fats the instrument may be warmed; the error introduced by weighing a slightly warm liquid in a small pipette being for practical purposes quite negligible.—A. R. L.

*Muffle for Sugar Assay.* H. Schweitzer and E. Lungwitz. Chem. Zeit. 18, 529.

For the determination of the ash in sugar by incineration, Scheibler recommends the use of a small muffle of platinum-foil which may be raised to a red heat. F. G. Wiechmann's sheet-iron muffles have only found limited application because they render the determination too slow. The disadvantages of the platinum muffle are its costliness—a large sugar laboratory requiring four or five,—

Fig. 1.

and the tendency to cause the fusion of the ash by superheating, the consequences of which are well known to every sugar-chemist. The muffle devised by the authors is much cheaper than the platinum muffle, permits of as rapid, and, if possible, more rapid work, and has none of its disadvantages. A strip is cut out longitudinally, as at *a* and *b* (Fig. 2), from a fireclay muffle. On the two ends

Fig. 2.

of the muffle *c d* (Fig. 1) platinum wires are stretched, *c c'* and *d d'* (Fig. 3), on which the platinum-foil *e f g h* (Fig. 2) is fastened. On the upper portion of the muffle a hole *x* (Fig. 3) is cut out. The platinum dishes are heated

on the sheet *e f g h*, which may also be of sheet iron. A good draught is generally obtained with a muffle of this construction, so that rapid incineration of the sugar is rendered possible. In spite of the large flame of the

Fig. 3.

so-called "Acme burner," the authors have never observed fusion of the ash. The use of an iron plate renders the assay more lengthy than when platinum is employed, but incineration is just as complete. A great saving of time and also of gas, in comparison to the amount of the latter consumed with fireclay muffles, is effected by employing the new form of muffle.—A. R. L.

**A New Extraction Apparatus.** L. Etai. Bull. Soc. Chim. 11, 1894, 259—260.

THE apparatus consists of an adapter (A), and ground so as to fit into this (2) a large tube, the lower end of which is several centimetres below that of the adapter, and the upper end of which opens laterally (C) into the upper part of the

adapter. The tube contains within it a smaller tube, curved to form a siphon, its shorter branch communicating with the interior of the adapter, its longer branch descending freely to the bottom of the large tube. To make use of the apparatus the tube is withdrawn from

the adapter, a ring of glass-wool introduced at the level of the opening of the siphon (*ca*), and a little glass wool also placed in the lower part of the adapter. The substance to be extracted is put into A, up to the level of the top of the siphon.

For extraction in the cold arrange the apparatus above some kind of reservoir, and below a dropping funnel, so that the solvent falls in drops on to the substance; the solvent accumulating finally covers the substance, and the level of the liquid being now above the curve of the siphon, the latter completely empties the adapter.

For a hot extraction, arrange the adapter above a flask (B), and connect it with an upright condenser (R). Introduce into the flask a volume of solvent at least equal to the total capacity of the adapter. On boiling the solvent, the vapour liquefies in the condenser, and falls back on to the substance, the further action being as before, with the addition that the vapour in passing upwards serves to keep at a boiling temperature the liquid covering the substance.

The apparatus is made by the firm of Alvergnyat, 10, Rue de la Sorbonne, Paris.—R. B. B.

**New Method of Estimating Pyknometrically the Densities of Soft Fats.** Zdzislaw Ziwalkiewicz. Monath. Chem. 15, 132—138.

In order to determine the relative density at the ordinary temperature, of a fat, &c., semi-solid at that temperature, a pyknometer is used with two orifices, Fig. 1: these are connected by means of india-rubber tubing with two glass tubes serving as reservoirs, *a* and *B*, Fig. 2; a brass ring *b*, supports these, together with a thermometer, *γ*, inside a bell-jar, A A, the interior of which can be heated as required by means of a series of small flames, *w w*. The bell-jar

Fig. 1.

rests on an annular support, B B, containing in its centre a vessel kept full of water, passing through from the outside reservoir B, as indicated by the arrows. To make an observation, the supporting-rod *b*<sub>2</sub> is raised, the larger reservoir *a* filled with the substance to be examined, and the flames *w w* lit; the material gradually melts, and descends into the pyknometer, ultimately filling it and rising up in the smaller reservoir *B*, until an equality of level subsists; in this way the pyknometer is completely

filled with the melted substance without air-bubbles; the temperature should not be more than some 20° above the melting point of the substance. The supporting-rod  $b_2$  is then lowered, so that the pyknometer is immersed in the water some 3 mm. deep. The cooling operation generally requires 1½ to 3 hours, the pyknometer being kept full from the reservoirs, as the warmer material contracts in

Fig. 2.

volume during cooling. Finally the india-rubber tubes, &c. are disconnected, and the pyknometer wiped and weighed. If  $P$  be the weight of the empty pyknometer,  $p$  that of pyknometer full of water, and  $p_2$  that of pyknometer full of fat, the specific gravity of the fat relatively to water is  $d = \frac{p - P}{p_2 - P}$ . Thus, samples of lanolin, yellow vaselin, lard, and butter-fat gave respectively the numbers 0.95178, 0.88273, 0.94083, and 0.93175 at 16°. On examining the density of lanolin at temperatures above and below its melting point, it was found that the rate of expansion was perceptibly greater in the semi-solid condition than at higher temperatures when completely melted; the average diminution in density per 12 rise of temperature being about 0.016 in the first case, and 0.007 in the second.—C. R. A. W.

#### PATENT.

*An Improvement in Hydrometers, Saccharometers, and such like Instruments.* H. S. Keating, Kensington, London. Eng. Pat. 24,266, December 16, 1893.

The graduated stem of a hydrometer or the like, consists of a tube, open at the top, and with a lateral opening below, so that when immersed in a liquid, the latter has free access to the interior of the graduated tube, and the displacement of the liquid is therefore due to the walls of the tube only. Of course, the air-bulb below the graduated tube is closed as usual. This form enables the graduated stem to be made much stouter and stronger, with a scale of great delicacy.—E. G. C.

#### INORGANIC CHEMISTRY.—QUALITATIVE.

*Qualitative Detection of Aluminium.* G. Neumann. Monatsh. Chem. 15, 53—54.

THE methods usually recommended for the qualitative detection of aluminium in presence of iron or chromium, are not entirely satisfactory. The treatment of the precipitate with caustic soda or potash to dissolve out alumina, involves either the use of absolutely pure alkali, or a check-experiment with the reagent as regards alumina and silica therein contained; and thus renders the detection of traces uncertain. Fusion with sodium nitrate, alone or together with sodium carbonate, requires a platinum vessel, porcelain being inadmissible. Classen recommends that the solution in hydrochloric acid should be boiled with excess of baryta-water and filtered; the alumina is precipitated from the filtrate by further boiling with ammonium chloride, noting that traces of barium carbonate may be thus thrown down, owing to absorption of  $\text{CO}_2$  from the air. The following mode of manipulation answers well: the mixed precipitate containing aluminium, iron, and chromium, obtained by means of barium carbonate, is boiled with baryta-water; the filtrate is acidulated with hydrochloric acid, and precipitated hot with dilute sulphuric acid; the filtrate from the barium sulphate thus formed is then treated with ammonia, which precipitates aluminium, if present.

—C. R. A. W.

#### The Qualitative Reactions of Gases.

*Researches upon the Phenomena of Oxidation and Chemical Properties of Gases. Parts I. and II.* F. C. Phillips. Amer. Chem. Journal 16, 163—187, and 16, 255—277. Parts I. and II.

IN the course of an exhaustive research into the nature, analysis, and origin of natural gas (see page 790), the author was impressed by the comparatively small amount of attention which has been hitherto paid to the qualitative analysis of gases generally, and has therefore collected together "the more important reactions of the commonly occurring gases." These reactions are classified as follows:—

1. Oxidation phenomena of hydrogen, carbon monoxide and hydrocarbons in the presence of certain finely-divided metals, and other oxidising agents.

2. Reactions between gases and various compounds in solution and (at high temperatures) when dry.

1. From the experimental investigation of the oxidation phenomena, which usually consisted in passing mixtures of air with hydrogen (10 per cent.), hydrocarbons (3 per cent.), or carbon monoxide (10 per cent.) over palladium, the following conclusions were drawn:—

The temperature of oxidation for mixtures of gaseous hydrocarbons with air is mainly dependent upon the solid bodies with which the gas is in contact.

Two phases may generally be observed in the oxidation process. At first only minute traces of  $\text{CO}_2$  are produced, but the amount gradually increases during the rise of the temperature "through 20, 30, or even more degrees," when suddenly an intense reaction takes place.

Oxidation, mixture and environment remaining constant, does not always take place at the same temperature.

The oxidation temperature is not materially influenced by variations in the proportion of hydrocarbon to air in the mixture. Passing the air and gas mixtures over heated palladium, the order of stability (resistance to oxidation) is: paraffin, acetylene, carbonic oxide, olefines. Hydrogen alone, among combustible gases, is oxidised in the cold.

The lower members of a given homologous series of hydrocarbons are more stable than the upper. "In all cases where air is in excess, oxidation is complete (i.e., yielding only carbon dioxide and water), even though a considerable portion of the hydrocarbon may escape unchanged." With an insufficient amount of air some carbon monoxide may be formed. In oxidation,  $\text{CO}_2$  and  $\text{H}_2\text{O}$  are simultaneously formed.

As regards activity of oxidising-power, the order of the metals is as follows:—Osmium, palladium, platinum, ruthenium, iridium, rhodium, gold. This oxidising-power is apparently not dependent upon atomic weight. The cause of the oxidising-power possessed by these metals is still obscure, for although the majority of them have a tendency to produce an unstable oxide which readily gives up its oxygen to the hydrocarbon, yet platinum, which is nearly as powerful as palladium in inducing oxidation, does not produce an oxide when heated in air. At a bright red heat and with excess of air, palladium asbestos is as efficient as ignited copper oxide, for the oxidation of hydrocarbons. Palladium asbestos containing 2 per cent. of the metal is nearly as efficient as that containing 30 per cent. The statements of Berliner (Ann. der Phys. Wied. n. F. [35], 791) that, in the reaction  $\text{H}_2 + \text{O} = \text{H}_2\text{O}$ , the catalytic action of Pt, Cu, Zn and Al begins at a fixed temperature (which is for these metals 270°, 280°, 350°, and above 440° respectively) and increases with rise of temperature, and that, at constant temperatures, constant quantities of  $\text{H}_2\text{O}$  are formed, are not confirmed by the experiments of the author.

Krause and Meyer state that, in the presence of Hg, hydrogen begins to oxidise at 305°, increasing temperature accelerating the reaction. In contact with glass only, hydrogen burns between the limits 605° and 730°.

2. Qualitative Reaction of Gases.—The recognition of any gas in a complex mixture is still often difficult; there

are but few "groups," like those of Fresenius in the case of metals, and the members of these greatly resemble one another.

The following groups are proposed:—

Group 1. Hydrogen.

Group 2. Carbon monoxide.

Group 3. Methane, ethane, propane, &c.

Group 4. Ethylene, propylene, trimethylene, &c.

Group 5. Acetylene, allylene, &c.

Group 6. Sulphur compounds: hydrogen sulphide, methyl sulphides, carbon oxysulphide (COS), carbon bisulphide.

Group 7. Carbon dioxide.

Ungrouped. Nitrogen, oxygen.

There must be taken into account, as well as the gases permanent under ordinary conditions, the vapours of liquids, such as those of benzene, the lower paraffins, olefines, &c.

It is found convenient to recognise, by their relative intensities, three classes of gas reactions, viz.: (1) those where the reaction is prompt and of quantitative value; e.g., between  $\text{CO}_2$  and  $\text{KHO}$ ; (2) where the reaction is slow, but, time being allowed, no less complete; e.g., the reduction of  $\text{PtCl}_4$  solution by  $\text{H}_2$ ; (3) where it is extremely slow, the products of the reaction being, even then, only present in traces; e.g., the reduction of  $\text{Fe}_2\text{Cl}_6$  solution by  $\text{H}_2$ .

For each gas the author describes two sets of reactions.

(1.) *Reactions in Solution.*—Solutions of palladium chloride, platinum chloride, gold chloride, silver nitrate, ammoniacal silver nitrate, iridium chloride, rhodium chloride, potassium ruthenate, cerium dioxide in dilute sulphuric acid, potassium permanganate (in solutions—neutral, alkaline, and acidulated with sulphuric acid), potassium bichromate acidulated with sulphuric acid, mercuric chloride, osmic acid, ferric chloride, potassium ferrieyanide, ruthenium chloride and fuming nitric acid were usually employed as reagents, though occasionally potassium permanganate crystals in concentrated sulphuric acid, chromic acid, bromine water, hydrogen peroxide, mercurous nitrate, calcium hypobromite in excess of lime-water, sulphuric acid 1·8 sp. gr., iodine in potassium iodide solution, and gold chloride in excess of potassium hydroxide were also employed.

(2.) *Reactions at High Temperatures.*—Here the temperature at which the gas effects the reduction of ruthenium, gold, rhodium, platinum, palladium and silver chlorides, silver bromide, silver iodide, and mercuric iodide, when slowly passed over each of these substances in a heated glass tube, is noted. For hydrogen these temperatures are  $190^\circ$ ,  $150^\circ$ ,  $200^\circ$ , below  $80^\circ$ , in the cold,  $270^\circ$ – $280^\circ$ ,  $330^\circ$ – $360^\circ$ ,  $350^\circ$ – $370^\circ$  respectively, while, as to mercuric iodide, this substance volatilises without reduction. In each case the test is conveniently carried out by passing the resulting gas ( $\text{HCl}$ , &c.) through a dilute solution of a silver salt, the furnace temperature being recorded as soon as precipitation occurs.

With regard to the action of hydrogen upon silver nitrate solution the author corroborates Pellet's observation (see *Comptes rend.* [78], 1132), that hydrogen is unable to reduce a perfectly neutral silver nitrate solution, and that reaction only occurs when some silver oxide is present as well. Russell (*J. Chem. Soc.* [27], 3) states that silver nitrate solution is reduced.

The reduction of palladium chloride by hydrogen occurs at the ordinary temperature; it is an exothermic reaction: thus—

Hence the heat of the completed reaction =  $17 \cdot 4$  cal.

In point of delicacy this reaction, as a test for hydrogen, is superior to all others; the occlusion of hydrogen by the reduced palladium has, however, so far prevented its use in quantitative analysis.

Among the very numerous reactions detailed and commented upon by the author, the following seem to possess particular interest:—

*Methane* and all hydrocarbon gases yield, when passed through a mixture of crystals of potassium permanganate and strong sulphuric acid, carbonic acid. This is a very delicate reaction.

*Ethane*, which is practically identical with methane as to its other reactions, quickly reduces potassium ruthenate, whereas methane only slowly effects reduction.

#### *Distinction between Carbon Monoxide and Olefines.*

(1.) Palladium chloride yields: with  $\text{CO}$ ;  $\text{CO}_2$ : with  $\text{C}_2\text{H}_4$ ; no  $\text{CO}_2$ . Both reduce the  $\text{PdCl}_2$ .

(2.) Platinum chloride yields: with  $\text{CO}$ ;  $\text{CO}_2$ , but not immediately  $\text{Pt}$ , with  $\text{C}_2\text{H}_4$ , no reaction.

(3.) Ammoniacal silver nitrate yields: with  $\text{CO}$ ,  $\text{Ag}$  and  $\text{NH}_4\text{NO}_2$ ; with olefines containing not more than four carbon atoms, no reaction.

(4.) Rhodium chloride: with  $\text{CO}$ ; a slow reduction; with  $\text{C}_2\text{H}_4$ , no reaction.

*Isobutylene* among olefines is distinguished by its reduction of cerium dioxide and its absorption of iodine from solutions of this element.

*Trimethylene*, a saturated hydrocarbon and therefore not properly included among the olefines, although isomeric with them, is distinguished from the olefines proper by giving no reaction with either osmic acid or neutral potassium permanganate.—E. R. B.

## INORGANIC CHEMISTRY.— QUANTITATIVE.

*Method and Apparatus for the Analysis of Zinc-Dust.*  
F. Meyer. *J. angew. Chem.* 1894, 231. (*This Journal*, 1894, 765.)

FRESENIUS' method of analysing zinc-dust by passing the hydrogen it evolves with dilute sulphuric acid over cupric oxide in a combustion tube and absorbing the water thus formed in suitable absorption-tubes, gives very accurate results, but is also very tedious. In the apparatus described below, the hydrogen is volumetrically estimated. The apparatus consists of the flask A, tap-joint B, three-way tap

C, burette D, with tap E, and bottle F. The tap-joint, by means of the three-way tap, can be connected either with the flask, which holds about 200 cc., or with the burette, which holds 400 cc., or by means of an india-rubber tube with the bottle, which has a capacity of 500 cc. The capacity of the burette is 250 cc. in the bulb, 140 cc. in the stem, and the latter is divided into  $\frac{1}{2}$  ccs. According to

these dimensions, the apparatus is adapted for the analysis of 1 gram. of samples of zinc-dust containing from 75 to 100 per cent. of metallic zinc, at a temperature of from 10° to 25° C., and a barometric pressure varying from 740 to 770 mm. Before using the apparatus all joints and taps are well greased. Then 1 gram. of zinc-dust is placed in the flask A, the latter connected with the tap-joint, and completely filled with water by placing the tap in the position 1. As soon as all the air is displaced from the flask, the tap is turned into position II., the tap-joint connected with the burette, and the latter filled with dilute sulphuric acid (1 : 3) contained in the bottle F, by lifting the bottle and opening tap E. The burette being full, tap E is closed and tap C brought into position III., when the acid begins to run into the flask. The hydrogen evolved rises into the burette, gradually displacing the dilute acid back into F. When the evolution of gas has ceased, temperature and pressure are noted, the gas in the burette brought under atmospheric pressure by lifting the bottle F, and the volume of the hydrogen observed. The percentage of metallic zinc in the sample is then ascertained by the equation—

$$\text{Percentage of Zn} = 100 \frac{V(b-f)}{760(1+0.00367t)} \times 0.00291135.$$

V = number of cc. of hydrogen, measured at the pressure *b* and temperature *t*; *f* = tension of aqueous vapour at *t*° C.  
—C. O. W.

*The Determination of Phosphoric Acid.* W. J. Williams, F. Bergami, and B. Terne. *J. Franklin Inst.* **137**, 126—128, 129—133, and 138—140.

THESE are three separate papers on the Pemberton method of determining phosphoric acid by titrating the yellow precipitate with standard alkali. (This Journal, 1894, 176). Mr. Williams considers the uranium-nitrate method to be sufficiently accurate for most purposes on an aqueous solution of phosphoric acid, but quite untrustworthy with phosphatic material dissolved in mineral acids, or even acetic acid. He describes a series of tests made to compare the Pemberton volumetric method with the ordinary gravimetric method, and concludes from them that, if Mr. Pemberton's instructions are faithfully carried out by a careful manipulator, the method is accurate and trustworthy, but that with careless or unskilful manipulation the possibilities of serious error are great. Mr. Bergami also describes a series of tests made to compare the Pemberton method with the official one, and is inclined to think the former the more accurate of the two, but he does not consider the number of tests he made great enough to prove the infallibility of it.

Dr. Terne, at whose request Mr. Bergami's tests were made, is of the opinion that the Pemberton method is as trustworthy as the official method, and, if anything, more accurate, whilst the saving of time it effects is a great advantage in a laboratory. He states that he has no hesitation in adopting it at the factory under his control (The Bagn and Sons Co.), though samples for shipment will, at course, have to be analysed according to the rules of the Association. He believes the method to be of sufficient interest to warrant an effort being made to get it adopted, at least as an alternative method, by the Association of Official Agricultural Chemists.—R. B. P.

*The Estimation of Ammonia by Means of the Colorimeter.* L. Hossay de Nagy Hossay. *Bull. Soc. Chim.* 1894, **11**, 216.

MINUTE quantities of ammonia can be most accurately estimated by means of Wolff's colorimeter and a Nessler's solution prepared by dissolving 2 grms. of potassium iodide in 5 cc. of water, adding to the hot solution 3 grms. of mercury iodide, letting the solution go perfectly cold, making another addition of 3 grms. of mercury iodide and 20 cc. of water. The precipitate thereby forming, is allowed to settle, the solution filtered, and to 20 cc. of the clear liquid, 30 cc. of 20 per cent. caustic potash solution

are added. This solution, which is ready for use when perfectly clear, is much more sensitive than the one indicated by Messrs. Hadow and Miller, and gives a distinct coloration with 0.02 mgrm. of ammonia in 110 cc. of water. 1 cc. of this solution is added to the 110 cc. of water contained in a tube of the Wolff colorimeter. The solutions to be examined should not contain more than 0.1 mgrm. of ammonia in 110 cc.

The colorimetric estimation of nitrous acid is best carried out according to Frommendorff's method by means of starch solution and potassium iodide. The solution to be tested should not contain more than from 0.01 to 0.04 mgrm. of nitrous acid in 100 cc. If the solution be too dilute, the reaction is a long time in appearing, and it is also necessary to protect the solution from the light. Preusse and Tiemann's metaphenylenediamine test gives bad results when carried out in the presence of free sulphuric acid. A further drawback is the rapid discoloration of the diamine solution on standing. Griess' test gives very satisfactory results if the solutions to be examined contain not more than 0.05 mgrm. of nitrous acid in 200 cc. The solutions of sulphuric acid and naphthylamine should be preserved separately. The results are equally satisfactory whether the reaction be carried out in the cold or accelerated by heating. The reagents are best employed in solution with acetic acid; sulphuric acid in excess is liable to retard the reaction considerably.

The colorimetric estimation of nitric acid is only possible by reducing this acid to ammonia. This is effected by adding to the solution to be tested from 5 to 6 grms. of reduced iron and sufficient sulphuric acid. Subsequently the solution is made alkaline with caustic potash, diluted with water, and distilled; two Peligot's tubes, each charged with 10 cc. of water and 1 cc. of standard sulphuric acid, serving as receivers. The results obtained may be as much as 5 per cent. too low.—C. O. W.

*The Volumetric Estimation of the Soluble Phosphoric Acid in Superphosphates.* W. Kalmann and K. Meissels. *Mitt. d. k. k. Techn. Gew. Museums*, **4**, 1894 (4, 5, and 6), 174—178.

THE method is based upon the difference of the behaviour of phosphates towards methyl-orange and phenolphthalein. In titrating phosphoric acid, using methyl-orange as an indicator, neutrality is reached when the salt  $\text{RH}_2\text{PO}_4$  has been formed, i.e., when one-third of the acid has been neutralised. With phenolphthalein, neutrality is obtained when the salt  $\text{R}_2\text{HPO}_4$  has been formed, i.e., when two-thirds of the acid have been neutralised. Thus, a solution of  $\text{CaH}_2(\text{PO}_4)_2$  appears neutral to methyl-orange, but acid to phenolphthalein. In titrating a solution of this salt in the presence of the last-named indicator the point of neutrality is reached by way of the reaction—

in other words, 8 mols. of NaOH are equivalent to 3 mols. of  $\text{P}_2\text{O}_5$ . These facts are applied in the analysis of superphosphates as follows:—Twenty grms. of the superphosphates are dissolved in 1,000 cc. of water. One hundred cc. of this solution are titrated with half-normal caustic soda, using methyl-orange as indicator. Then phenolphthalein is added and the titration continued until change of colour occurs, when the number of cc. used is noted (*a*). Another volume of 100 cc. of the original solution is then placed in a 250-cc. flask, a moderate excess of half-normal caustic soda added, the flask well shaken, filled up to the mark with water, and filtered. One hundred cc. of the filtrate are titrated with half-normal acid and phenolphthalein as an indicator; then methyl-orange is added, and the titration continued. The number of cc. used is multiplied by 2.5 (*b*). The mean of the sum of *a* and *b* multiplied by 0.0355 then shows the number of grms. of  $\text{P}_2\text{O}_5$  contained in 100 cc. of the original solution, i.e., in 2 grms. of the superphosphate. The following table shows the results obtained by this as against the citrate method.

—C. O. W.

*The Volumetric Estimation of Phosphoric Acid.*A. F. Holleman. *Rec. des Trav. Chim. des Pays-Bas*, **12**, 1.

This method is applicable to all those cases where the phosphoric acid is present in the free state, or in combination with the alkalis or alkaline earths. If the solutions contain alumina or iron, a correction is necessary. Any heavy metals present are first eliminated by means of sulphuretted hydrogen. The method is not generally applicable in the presence of metals of the third group. The solutions may contain sulphuric and nitric acid, but should not contain any hydrochloric acid.

The solution, if acid, is exactly neutralised by means of a dilute solution of sodium carbonate, and is precipitated by means of an excess of standard silver nitrate. The precipitation is rendered complete by the addition of sodium acetate. The liquid is then filtered, being kept protected from the light. Subsequently the uncombined silver is estimated volumetrically in the filtrate.—C. O. W.

**ORGANIC CHEMISTRY.—QUALITATIVE.**

*Yellow Prussiate of Potash and the Detection of Hydrocyanic Acid in the Presence of Ferrocyanides.* W. Antenrieth. *Arch. Chem. Pharm.* **213**, 99.

CONTRARY to general notions, potassium ferrocyanide is partially decomposed at ordinary temperatures into hydrocyanic acid by dilute (0.1 per cent.) mineral acids, formic, acetic, butyric, lactic, tartaric and benzoic acid. Carbonic acid, sulphuretted hydrogen, the phenols, acetylacetic ether, and certain acid sulphones produce the same reaction at temperatures below 100° C. At the same time a very stable white ferrous ferrocyanide,  $\text{Fe}(\text{Cy})_6\text{FeK}_2$ , is formed, which, on exposure to the air, is not transformed into Prussian blue. The formation of Prussian blue in the preparation of hydrocyanic acid can be explained in two ways. Either the sulphuric acid decomposes the ferrous ferrocyanide, forming ferrous sulphate, which, in the presence of air, acts upon the hydrocyanic acid, or the sulphuric acid liberates some hydroferrocyanic acid, which is converted into Prussian blue according to the formula—

The action of the carbonic acid upon the yellow prussiate is accordingly—

The gastric juice decomposes the ferrocyanide at 40° C. The peptones and casein at 38° C. produce only traces of hydrocyanic acid, large quantities at a boiling temperature. Hydrocyanic acid not being retained by the tissues, it follows that yellow prussiate has no toxic action, as it is not absorbed simultaneously with acids. These observations

show that the usual method of detecting hydrocyanic acid and cyanides in the presence of ferrocyanides by distillation in a current of carbonic acid cannot legitimately be employed. Jacquemin proposed to distil the mixture with sodium bicarbonate, which does not decompose ferrocyanides, and in this manner 0.01 grm. of cyanide may be detected in a 10 per cent. solution of ferrocyanide. If the presence of mercurous cyanide be suspected, a few cc. of sulphuretted hydrogen water are added. Mercurous cyanide is very stable towards alkalis, alkaline carbonates, and dilute acids. To detect it in forensic investigations the substance is distilled with tartaric acid and a concentrated solution of sulphuretted hydrogen. Mercury cyanide is fairly soluble in ether, but cannot be extracted from aqueous solutions by means of that solvent.—C. O. W.

*Camphor as a Reagent for Sugar.* Neitzel. *Deutsch. Zuckerind.* **17**, 254.

The author recommends camphor instead of  $\alpha$ -naphthol as a reagent for sugar. Camphor is available for the detection of the smallest quantities of sugar met with in commercial investigations, but is not, like  $\alpha$ -naphthol, affected by the presence of small quantities of nitrates.—A. R. L.

**ORGANIC CHEMISTRY.—QUANTITATIVE.**

*The Analytical Constants of Seal Oil.* A. C. Chapman and J. R. Rolfe. *Chem. News*, 1894, **70**, 1—2.

THE usual analytical figures for oils have been scantily recorded in the case of seal oil, and the authors therefore give the following table for six samples obtained from reliable sources. They also quote the results obtained from a sample of seal oil blown for 45 hours at a temperature of 190° F.

A study of these figures leads to the following conclusions:—The specific gravity of the oil varies but little save in the case of the "brown seal," which is low in specific gravity, probably from the presence of much free fatty acid. The melting-points of insoluble fatty acids were determined by the capillary tube method, the point at which flow began being taken. The iodine absorption was carried out as usual with a large excess of iodine, the time adopted being five hours. Absorption continued on increasing the time, so that values of 140 to 151 were obtained after 12 hours. The bromine absorption was performed by the method prescribed by Mills and Snodgrass (*this Journal*, 1883, 435); 0.15 grm. of oil was dissolved in 25 cc. of dry, redistilled carbon disulphide, excess of a solution of bromine in the same solvent added, and the mixture allowed to stand in the dark for 15 minutes. Addition of potassium iodide and titration of the liberated iodine completed the

operation. On increasing the time of absorption to one hour the bromine absorption increased, figures as high as 89 being obtained, but in this case substitution as well as addition of bromine took place, as was evident from the evolution of hydrobromic acid. The authors note that the results of the iodine absorption are usually more regular than those of the bromine absorption, the former being less influenced by slight variations of the conditions of experiment. The series of figures recorded under the head "total acid number" refers to the percentages of caustic potash needed for the saponification of the oils. The results given in the column headed "Reichert's test" express the weight of caustic potash in grams required to neutralise the volatile fatty acids obtained from 100 grms. of the oil—2.5 grms. being used in the experiments. The determination was made in order to ascertain what difference is produced when seal oil is blown. With regard to the blown seal examined it is mentioned that whereas the unblown oils had viscosities varying from 60 to 64 at 15° C. (rape oil at the same temperature being taken as 100), the blown oil was so viscous that at 50° C. it took 63 times as long to flow through a standard orifice as did the same volume of rape oil.—B. B.

*Acidimetric Estimation of Naphthalene, Acenaphthene,  $\alpha$ - and  $\beta$ -Naphthol, &c.* F. W. Küster. Ber. 27, 1101—1105.

THIS method of estimation applies only to such substances as form insoluble molecular compounds with picric acid. If naphthalene, acenaphthene, chrysene, or one of the naphthols be digested on the water-bath with a measured quantity of an aqueous solution of picric acid (nearly saturated at ordinary temperatures = about 0.05 normal) the original substance gradually disappears, and in its place an equivalent quantity of the molecular picric acid compound separates out quantitatively either at once or on cooling. The amount of picric acid in the original solution and in an aliquot portion of the filtrate from the molecular compound can easily be determined by titration with decinormal barium hydroxide (using lacmoid as indicator), and from these data it is easy to calculate the quantity of picric acid contained in the precipitate. Simple multiplication by the equivalent factor then gives the amount of naphthalene, &c., taken.

The digestion on the water-bath must take place in hermetically-closed vessels. For this purpose, the author recommends the following process:—The substance to be determined, together with the measured volume of picric acid of known strength in excess, is placed in a flask, which must be nearly filled with the solution. The flask is then closed with a good india-rubber stopper, through which passes a tube about 7 cm. long. The tube is sealed up at the lower end, and about 1.5 cm. above the sealed end there is blown a small hole in the side. When the side hole is just below the stopper the air in the flask may be pumped out; then, on withdrawing the tube until the sealed end is flush with the under side of the stopper, the

flask, having a vacuum in the upper part, may be disconnected from the pump and safely heated in the water-bath. The flask must be heated until the reaction is complete (2 hours—2 days), and frequently shaken during cooling, in order to wash down any naphthalene, &c. which may have sublimed into the upper part of the flask. After standing for a few hours, the picric acid in the filtrate is determined by titration.

The author gives several series of test analyses which show that the method is very exact, except in the case of  $\beta$ -naphthol, where a correction must be introduced owing to the solubility of the molecular compound. For every 100 cc. of picric acid solution, 0.0075 gm. of  $\beta$ -naphthol remains unprecipitated.—J. S.

*Composition and Analysis of Yeast.* T. Guichard. Bull. Soc. Chim. 1894, 11, 230.

THE moisture in yeast is estimated by drying the yeast cut into small shavings, at 120° C. Pure yeast contains 71 per cent. of moisture. It loses the whole of its moisture over calcium chloride, and all but 7 per cent. over sulphuric acid. With its moisture it also loses its fermenting capacity. The specific gravity of yeast (by suspension in a mixture of alcohol and chloroform) was found to be 1.180 (in a solution of hyposulphite (thiosulphate) of soda) the figures 1.180 and 1.183 were obtained at 16° C. Water agitated with pure yeast does not reduce Fehling's solution. The residue obtained on boiling yeast with alcohol and evaporating the latter, has no reducing action, but gives a precipitate with barium hydrate. Yeast contains always traces of starch, amounting to from 0 to 2.04 per cent. On ignition moist yeast yields from 1.94 to 2.16 per cent. of ash. The percentage of nitrogen estimated by Kjeldahl's and the soda-lime processes was found to be 5.32 and 6.16 per cent. respectively, corresponding respectively to 33.25 and 38.50 per cent. of nitrogenous matter. This nitrogenous matter consists of nucleine. Petroleum ether extracts from yeast 1.4 per cent. of fatty matter. Starch added to yeast is estimated by boiling for one hour, with reflux condenser, 10 grms. of the yeast with 100 cc. of dilute (5 per cent.) nitric acid. The liquid after cooling is filtered, if necessary, decolorised by means of animal charcoal, and examined in the polarimeter. By multiplying the number of degrees observed by 8.52, the result gives the percentage of anhydrous starch in the yeast; by multiplying by 9.3 the percentage of air-dry starch is obtained. The quantities of added starch in commercial yeast range from 6.2 to 35 per cent. The results of the chemical analysis of yeast are not sufficient to test its quality; for this reason the fermenting capacity of a sample should also be examined. For the purpose the following new process is proposed. An apparatus is employed consisting of a small bulb with a lateral orifice. The bulb is further provided with a long vertical tube, over which is placed concentrically a wider tube divided into 100 cc. This tube is filled with water, which through a lateral tube, is displaced by the carbonic acid, subsequently

developed in the test. In the bulb is placed 0.5 grm. of the yeast to be examined, diluted with 0.5 grm. of water, 0.5 grm. of sugar dissolved in 5 cc. of water, and 1 grm. of washed sawdust. The lateral orifice of the bulb is then closed with an india-rubber stopper, and the apparatus placed in a water bath at 30° C. The quantity of carbonic acid is then observed every quarter of an hour for two hours and a half. The different readings may be marked on a system of co-ordinates, and a curve is thus obtained rising rapidly to a maximum and falling again with equal rapidity. The flatter the curve the poorer the fermentative quality of the yeast. Otherwise the quantity of carbonic acid evolved is taken as a measure of the quality of a yeast. The strongest yeast examined, evolved 86.2 cc. of carbonic acid in two and a half hours.—C. O. W.

*Gravimetric Methods for Estimating Sugars by their Cupric Reducing Power.* L. Grünhut. Chem. Zeit. **18**, 447—448.

For the gravimetric estimation of sugars Nihoul (Chem. Zeit. **17**, 500) recommends a modified form of the older paper-filtration method, in which the collected cuprous oxide is weighed as cupric oxide, in the place of the more recent asbestos-filtration method, in which the copper is weighed as metal. The experience of the present author is that the paper-filtration method not only gives non-concordant results, but also results which are too low. Experiments in support of this are described. The cause appears to be that cuprous oxide is not completely converted into cupric oxide by one treatment with nitric acid (compare Pavy, Zeits. Zuckerind., 1879, **29**, 291; Allihn, *ibid.* 1882, **32**, 878). When the ignition is performed by a gas-flame the reducing action of the latter appears to have considerable influence on the results. Soxhlet asserts (Zeits. Zuckerind., 1878, **28**, 373) that basic copper nitrate is volatile at 200°, and in view of the possibility of this being the cause of the low results the, the author re-investigated the matter, although Nihoul's experiments refute Soxhlet's observation. The author finds, however, that it is possible to obtain the theoretical quantity of cupric oxide by heating the nitrate for a long time at 200°. It is further shown that the cupric oxide finally obtained contained the same quantity of copper as was originally present in the nitrate. (Compare following abstract.)—A. R. L.

*Gravimetric Methods for the Estimation of Sugars by their Cupric Reducing Power.* E. Nihoul. Chem. Zeit. **18**, 881—882.

In reply to Grünhut (see last abstract) the author quotes experiments showing that the paper-filtration method is more accurate than the asbestos-filtration method. His contention is that the results obtained by the former method are accurate, whilst those obtained by the latter are too high, on account of the retention of organic matter by the asbestos-filter, which is not got rid of by ignition in a current of hydrogen. As to the reducing action of the flame, this is practically nil when not too large a flame is used together with a closed crucible.—A. R. L.

## ANALYTICAL AND SCIENTIFIC NOTES.

*Preparation of Phosphorus by means of the Reducing Action of Aluminium upon Phosphates and on the Oxidation and Inflammation of Aluminium by Sodium Peroxide.* A. Rossel. Bull. Soc. Chim. 1894, **11** 260.

On heating in a test-tube or porcelain crucible a quantity of sodium metaphosphate in contact with aluminium foil, the metal begins to fuse at the same temperature as the phosphate, the mixture inflames, and phosphoric anhydride is formed. If this reaction be carried out in an atmosphere of hydrogen, a distillate of phosphorus is obtained. This reaction may be shown as a lecture experiment. The analytical investigation of the reaction showed the latter to result in the formation of sodium aluminate, but at the same time a compound of aluminium and phosphorus is formed

which is not decomposed by heat but evolves phosphoretted hydrogen in the presence of water. This aluminium phosphide possesses the formula  $AlP_3$ , and it is obtained in the pure state by heating aluminium in a current of gaseous phosphorus. By the above reaction only about 3 per cent. of the phosphorus contained in the metaphosphate are obtained in the free state, but by adding silicic acid to the mass almost the theoretical yield of phosphorus is obtained according to the equation—

The same reaction takes place with metaphosphate of lime and more or less with all the other phosphates of lime excepting apatite. Superphosphates react so violently as to cause an explosion. Of a similarly violent character is the reaction between the sulphates of the alkaline earth metals and aluminium, which results in the formation of free sulphur.

Sodium peroxide is a most useful oxidising agent, which, however, should be used with some caution. Mixtures of aluminium and sodium peroxide ignite spontaneously with great violence and production of a high temperature.

—C. O. W.

*Formation of Sugar in the Liver.* G. Cavazzani. Centralbl. f. Physiol. **8**, 33.

THE quantitative estimation of glycogen and of glucose in the livers of living and dead animal shows (in the case of the latter the relation is exact) that the decrease in the amount of glycogen corresponds with the increase in that of sugar. The author is therefore of opinion, contrary to Seegen's view, that the formation of sugar in the liver takes place chiefly (probably exclusively) at the expense of the glycogen therein contained. The formation of sugar appears to be a true secretion process of the liver, influenced by special nerves.—A. R. L.

## New Books.

TECHNISCH-CHEMISCHES JAHRBUCH. 1892—1893. Ein Bericht über die Fortschritte auf dem Gebiete der Chemischen Technologie vom April 1892 bis April 1893. Herausgegeben von Dr. RUDOLF BIEDERMANN. Fünfzehnter Jahrgang. Mit 240 in den Text gedruckten Illustrationen. Berlin: Carl Heymann's Verlag. 1894. London: H. Grevel and Co., 33, King Street, Covent Garden. 12s.

For 15 years this Year-book of Chemical Technology has now appeared. In this, its last issue, it forms a substantial 8vo volume bound in cloth. An exceedingly useful feature in it is the "Bücherschau," or Report of New Books on various branches of science that have appeared during the year. This report is well classified, and deals with works on: 1. Physics. 2. Chemistry. 3. Chemical Technology. 4. Mineralogy, Geology, and Mining. 5. Miscellaneous. The work commences with an elaborate table of contents, followed by one of the journals of technology and science referred to in its pages. The subject-matter fills 550 pages, which are illustrated by 241 wood engravings. The subjects treated of are: I. Iron and Steel. II. The Alkali Metals. III. Gold and Silver. IV. Copper. V. Lead. VI. Zinc. VII. Tin. VIII. Nickel and Cobalt. IX. Tungsten, Chromium, Platinum Metals, Manganese, and Mercury. X. Chlorine, Bromine, and Hydrochloric Acid. XI. Sulphur, Sulphuric Acid. XII. Oxygen, Carbonic Acid, Nitric Acid. XIII. Soda. XIV. Potash Salts. XV. Ammonia and Cyanogen Compounds. XVI. Alkaline Earths, &c. XVII. Glass. XVIII. Earthenware. XIX. Cement. XX. Artificial Stone. XXI. Explosives. XXII. Illuminants. XXIII. Fuel. XXIV. Sugar. XXV. Starch, &c. XXVI. Wine. XXVII. Beer. XXVIII. Spirits. XXIX.

Fats, Soaps, Ethereal Oils, and Resins. XXX. Water. XXXI. Foodstuffs. XXXII. Manures. XXXIII. Organic Acids. XXXIV. Alkaloids. XXXV. Colouring Matters. XXXVI. Tanning. XXXVII. Glue and other Adhesives. XXXVIII. Textile Fibres. XXXIX. Paper. XL. Photography. XLI. Apparatus. The work concludes with an alphabetical index of authors and subject-matter, and a separate, well-classified index and list of patents, under headings corresponding with those specified above. This index thus serves also a separate and useful purpose, *viz.*, that of a classified record of patents published in the year.

**CHEMISCH-TECHNISCHES REPERTORIUM. UEBERSICHTLICH GEORDNETE MITTHEILUNGEN DER NEUESTEN ERFINDEUNGEN, FORTSCHRITTE UND VERBESSERUNGEN AUF DEM GEBIETE DER TECHNISCHEN UND INDUSTRIELLEN CHEMIE, MIT HINWEIS AUF MASCHINEN, APPARATE UND LITERATUR.** Herausgegeben von Dr. EMIL JACOBSEN. 1893. Zweites Halbjahr. Erste Hälfte. Mit in den Text gedruckten Illustrationen. 1894. Berlin: R. Gaertner's Verlagsbuchhandlung, Hermann Heyfelder, Schönebergerstr. 26, S.W. London: H. Grevel and Co., 33, King Street, Covent Garden.

This is the first issue for the second half-year of 1894, of Dr. Jacobsen's Repertory of Chemical Technology. It contains reports of the progress of the following branches of Chemical Industry:—Building Materials. Dyestuffs, Dyeing, and Calico-printing. Fats, Oils, &c. Fermented Liquors, Tanning, Leather, Glue, &c. Textiles. Glass and Pottery. Wood, &c. India-rubber. Cements, Adhesives, &c. Lakes, Varnishes, and Paints. Metals. The subject-matter covers altogether 200 pages. The issues of this work are quarterly.

**SELECT METHODS IN CHEMICAL ANALYSIS (CHIEFLY INORGANIC).** By WILLIAM CROOKES, F.R.S., Editor of the Chemical News. Third Edition, Rewritten and Enlarged. Illustrated with 67 wood-cuts. London: Longmans, Green and Co. New York: 15, East 16th Street. 1894. 21s.

In this, the third edition of the above-named well-known work, it is stated that such methods as have become thoroughly established since the issue of the second edition, are now removed, and replaced by others which have been proposed and found to be successful during the last eight years. It is also stated, that it must not be assumed, then, that processes thus discarded have ceased to possess value; they are in some cases thoroughly established, but the author, desiring this work to be mainly a collection of novel or little-known processes—"Select Methods,"—has consequently removed them. Other methods have of course disappeared, because, being tried, they have been found less effective than the substitutes now appearing. The book is one of large 8vo. size, and is strongly bound in cloth. It contains a well-classified table of contents, 697 pages of subject-matter, and an alphabetical Index. The last 10 pages of the work are devoted to "Useful Tables": 1. Conversion of Centigrade and Fahrenheit Degrees. 2. Mutual Conversion of French into English Weights and Measures. 3. Relative Values of French and English Weights and Measures. Baume's Hydrometer, Twaddell's Hydrometer, &c., &c.

The methods specified are comprised under the following headings and chapters:—I. Potassium, Sodium, Lithium, Cesium, and Rubidium (Ammonium). II. Barium, Calcium, Strontium, Magnesium. III. The Cerium Group. IV. Chromium, Uranium, &c. V. Zinc, Aluminium, Gallium, and Iron. VI. Manganese, Nickel, Cobalt. VII. Silver, Mercury, Copper. VIII. Cadmium, Gallium, Lead, Thallium, Indium, Bismuth. IX. Antimony, Tin, Arsenic, Tellurium, Selenium. X. Gold, Platinum, Palladium, Iridium, Osmium, &c. XI. Sulphur, Phosphorus, Nitrogen. XII. Iodine, Bromine, Chlorine, Fluorine (Cyanogen). XIII. Carbon, Boron, Silicium. XIV. Electrolytic Analysis, Gas Analysis. XV. Miscellaneous Processes and General Methods of Manipulation.

**JAHRBUCH DER CHEMIE.** Herausgegeben von RICHARD MEYER. Bericht über die Wichtigsten Fortschritte der Reinen und Angewandten Chemie, unter Mitwirkung von H. Beckurts, R. Benedikt, C. A. Bischoff, E. F. Dürre, J. M. Eder, C. Häussermann, G. Krüss, M. Märcker, W. Nernst, and F. Röhmman. III. Jahrgang. 1893. Braunschweig: Friedrich Vieweg und Sohn. 1894. 15s. Extra finely bound, 16s. 6d. London: H. Grevel and Co., 33, King Street, Covent Garden.

This is a handsomely and strongly bound volume of 8vo size, containing Table of Contents, 548 pages of Subject-Matter, and an Alphabetical Index of Subjects and Names of Authors. The subjects treated of are:—I. Physical Chemistry (By W. Nernst). II. Inorganic Chemistry (G. Krüss); Organic Chemistry (C. A. Bischoff). IV. Physiological Chemistry (F. Röhmman). V. Pharmacoeutical Chemistry (H. Beckurts). VI. Chemistry of Foods, &c. (H. Beckurts). VII. Agricultural Chemistry (W. Märcker and W. Schneidewind). VIII. Metallurgy (E. F. Dürre). IX. Fuels and Inorganic Chemical Technology (C. Häussermann). X. Explosives (C. Häussermann). XI. Technology of the Carbohydrates and Fermentation Industries (Märcker, Bühring, and Schneidewind). XII. Coal-tar and Colour-Chemistry (Richard Meyer). XIII. Chemical Technology of Textile Fibres (Richard Meyer). XIV. Photography (J. M. Eder and E. Valenta).

**MINERAL RESOURCES OF THE UNITED STATES, CALENDAR YEAR 1893.** DAVID T. DAY, Chief of Division of Mining Statistics and Technology. Washington: Government Printing Office. 1894. 50 cents.

LARGE 8vo volume, strongly bound in black cloth. It contains a Table of Contents, Letter of Transmittal, Introduction, and 794 pages of subject-matter, concluded by an alphabetical index.

This well-classified report of the Mineral Resources of the United States is itself a mine of valuable information, and deals with the following minerals, metals, &c., found and exploited in the United States of America:—

Iron, Gold and Silver, Copper, Lead, Zinc, Quicksilver, Manganese, Aluminium, Bauxite, Nickel and Cobalt, Tin, Antimony, Coal, Pennsylvania Anthracite (Coke), Petroleum, Natural Gas, Stone, Clays, Cements, Soapstone, Asphaltum, Abrasive Materials, Precious Stones, Fertilisers, Gypsum, Salt, Natural Sodium Salts, Sulphur and Pyrites, Fluorspar, Mica, Asbestos, Mineral Paints, Graphite, Barytes, and Mineral Waters.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

#### CANADIAN TARIFF CHANGES—concluded.

##### Free List.

Boric acid and borax in bulk of not less than 25 lb., bromine, celluloid, chloride of lime, cinnabar, cobalt ore, cochineal, colours (metallie), copper precipitate, cyanide of potassium, drugs (crude), dyeing or tanning articles (crude), fertilisers (unmanufactured), gums, gutta percha (crude), iodine (crude), iron liquor, lead nitrate and acetate (unground), lime juice (crude), litharge, oxide of manganese, nickel, oils, oxalic acid, phosphorus, platinum, plumbago crucibles, potash, chlorate, bichromate, prussiate, and caustic in bulk; potassium chloride, quicksilver, quinine, red liquor (aluminium acetate), rosin and rosin oil, rubber (unmanufactured), salt, soda and its salts, sulphates of iron and copper, tartar emetic, turpentine (crude), ultramarine blue, varnish for ships' use.—*Board of Trade Journal.*

## THE NETHERLANDS.

*Exemption of Naphthalene from Import Duty.*

Mr. C. L. des Graz, Her Majesty's Chargé d'Affaires at The Hague, in a despatch to the Foreign Office, dated the 27th July, transmits copy and translation of a decision (*resolatie*), dated July 21st, emanating from the Minister of Finance, and published in the *Staatscourant*, to the effect that naphthalene, purified or unpurified, in powder, crystals, or irregular pieces, is free of import duty.—*Ibid.*

## THE UNITED STATES TARIFF.

We give below as nearly as can be at present ascertained the duties on drugs, chemicals, and other goods dealt in by druggists as fixed by the tariff bill which has just been adopted by the Conference between the Senate and the Congress in Washington, and will become law on August 25, or earlier if the bill is signed by the President. We quote these from the bill as it left the Senate. There may have been some modifications made since, but substantially we believe the table as we give it to be correct.

	Present Duty.	Future Duty.
<i>Drugs and Chemicals.</i>		
Acetic or pyroligneous acid .....	1½ c. to 4 c. per lb.	20 per cent.
Boracic acid .....	5 c. per lb.	2 c. per lb.
Chromic acid .....	6 c. "	4 c. "
Citric acid .....	10 c. "	25 per cent.
Tannic acid or tannin .....	75 c. "	60 c. per lb.
Tartaric acid .....	10 c. "	20 per cent.
Alcoholic perfumery, including Cologne water and other toilet waters, and alcoholic compounds not specially provided for .....	\$2 per gall. and 50 per cent. to \$2 per gall. and 25 per cent.	\$2 per gall. and 50 per cent.
Alumina, alum, alum cake, patent alum, sulphate of alumina and aluminous cake, and alum in crystals or ground .....	½ c. per lb.	½ c. per lb.
Ammonia, carbonate of, marlate of, or sal ammoniac, sulphate of .....	½ c. to 1½ c. per lb.	20 and 10 and 20 per cent.
Blackening of all kinds .....	25 per cent.	20 per cent.
Borax, crude, or borate of soda, or borate of lime, refined borax .....	3 c. to 5 c. per lb.	1 c. to 2 c. per lb.
Camphor, refined .....	4 c. per lb.	10 per cent.
Chalk, prepared, precipitated, French, red, and all other chalk preparations not specially provided for .....	20 per cent.	20 "
Chloral hydrate .....	50 c. per lb.	25 "
Chloroform .....	25 c. "	25 c. per lb.
All coal tar colours or dyes, by whatever name known, and not specially provided for .....	30 per cent.	25 per cent.
Cobalt, oxide of .....	30 c. per lb.	25 c. per lb.
Collodion and all compounds of pyroxylin .....	60 c. per lb. to 25 per cent.	40 c. and 50 c. per lb. to 45 per cent.
Quicksilver .....	10 c. per lb.	7 c. per lb.
Colouring for liquors .....	50 per cent.	50 per cent.
Drugs, such as barks, beans, berries, balsams, bulbs, bulbous roots, exscrecences, fruits, flowers, dried fibres, dried insects, grains, gums and gum resin, herbs, leaves, lichens, mosses, nuts, roots and stems, spices, vegetables, seeds aromatic (not garden seeds), seeds of morbid growth, weeds, and woods used expressly for dyeing; any of the foregoing drugs which are not edible, advanced in value or condition by re-refining or grinding .....	10 "	10 "
Extracts and decoctions of log-wood and other dyewoods, extract of sumac .....	½ c. per lb.	10 "
Extract of hemlock-bark .....	½ c. "	10 "

## THE UNITED STATES TARIFF—continued.

	Present Duty.	Future Duty.
Sulphuric ether .....	40 c. per lb.	40 c. per lb.
Spirit of nitrous ether .....	25 c. "	25 c. "
Fruit ethers or essences .....	\$2.50 "	\$2.50 "
Ethers not provided for .....	\$1.00 "	\$1.00 "
Gelatin, glue, isoglass, or fish-gline, and fish-sandals .....	1 c. per lb. and 20 to 30 per cent.	25 c. per lb.
Glycerine, crude and refined .....	1½ c. to 4 c. per lb.	1 c. to 1½ c. per lb.
Ink, ink-powders, and printers' inks .....	30 per cent.	25 per cent.
Iodoform .....	\$1.50 per lb.	\$1.50 per lb.
Lignin, extracts of, in paste, rolls, or other forms .....	50 c. "	50 c. "
Morphine and all salts thereof .....	50 c. per lb.	50 c. per lb.
Magnesia, carbonate of .....	1 c. per lb.	3 c. per lb.
Magnesia, calcined .....	8 c. "	7 c. "
Magnesia, sulphate of .....	3 c. "	3 c. "
Opium, aqueous extract of, for medicinal uses, and tincture of, as Laudanum .....	40 per cent.	20 per cent.
Opium, containing less than 9 per cent. of morphine, and opium prepared for smoking .....	\$12 per lb.	\$6 per lb.
<i>Medicinal Preparations.</i>		
All medicinal preparations of which alcohol is a component part, or in the preparation of which alcohol is used, not provided for in this Act .....	50 c. "	50 c. "
All medicinal preparations, not specially provided for in this Act .....	25 per cent.	25 per cent.
Alkalis, alkaloids, distilled oils, essential oils, expressed oils, rendered oils, and all combinations not specially provided for .....	25 "	25 "
Cosmetics, dentifrices, pastes, pomades, powders, and all toilet preparations and articles of perfumery not specially provided for .....	50 "	40 "
Santonine and all salts thereof containing 80 per cent. or over of santonine .....	\$2.50 per lb.	\$1.00 per lb.
Phosphorus .....	20 c. "	25 c. "
<i>P. Fish.</i>		
Bichromate and chromate of .....	3 c. "	25 per cent.
Hydriodate, iodide, and iodate of .....	50 c. "	25 c. per lb.
Nitrate of, or saltpetre, refined .....	1 c. "	1 c. "
Prussiate of, red or yellow .....	5 c. to 10 c. per lb.	25 per cent.
<i>Oils.</i>		
Alizarin assistant, or Turkey oil .....	40 c. to 80 c. per gall. to 30 per cent.	30 "
Castor oil .....	80 c. per gall.	35 c. per gall.
Cod-liver oil .....	50 c. "	20 per cent.
Linseed and poppy-seed oil, raw, boiled, or oxidised .....	32 c. "	20 c. per gall.
Fusel oil, or amyl alcohol .....	10 per cent.	10 per cent.
Hemp-seed oil and rape-seed oil .....	10 c. per gall.	10 c. per gall.
Olive oil, fit for salad purposes .....	35 c. "	35 c. "
Peppermint oil .....	80 c. "	25 per cent.
Seal, herring, whale, and other fish oil .....	8 c. "	25 "
<i>Paints, Colours, and Varnishes.</i>		
Baryta, sulphate of, or barytes, manufactured .....	\$1.12 to \$6.72 per ton.	\$3.00 per ton.
Blues, such as Berlin, Prussian, Chinese .....	6 c. per lb.	6 c. per lb.

## THE UNITED STATES TARIFF—continued.

	Present Duty.	Future Duty.
Blue fixe, or artificial sulphate of barytes, and satin white, or artificial sulphate of lime.	1 c. per lb.	25 per cent.
Black, made from bone, ivory, or vegetable.	25 per cent.	20 "
Paris green and London purple.	"	12½ "
Chrome yellow, chrome green, and other chromium colours.	4½ c. per lb.	3 c. per lb.
Olive and ochre earths, sienna, and sienna earths, amber and amber earths, ground in oil.	1 c. to 1½ c. per lb.	1½ c. "
Ultramarine blue, whether dry, in pulp, or mixed with water, and wash-blue containing ultramarine.	4½ c. per lb.	3 c. "
Varnishes, including so-called gold-stone or japan, and on spirit varnishes for the alcohol contained therein.	35 per cent. to 35 per cent., and \$1.32 per gall.	25 per cent. to 25 per cent., and \$1.32 per gall.
Vermilion red, and other colours containing quicksilver, dry or ground, in oil or water, and vermilion red not containing quicksilver, but made of lead or containing lead.	12 c. per lb.	20 per cent. to 6 c. per lb.
Milting and Paris white.	3 c. "	1 c. to 1½ c. per lb.
Zinc, oxide of, and white zinc, gold-stone, dry or ground, in oil.	1½ c. to 1½ c. per lb.	1 c. per lb.
All other paints, colours, and pigments, whether dry or mixed, or ground in water or oil, or other solutions, including tubes, lakes, crayons, smalts, and frostings, and not specially provided for.	25 per cent. to 30 per cent.	25 per cent.
<i>Liquid Products.</i>		
Acetate of lead.	2½ c. to 5½ c. per lb.	1½ c. to 2½ c. per lb.
Litharge.	3 c. per lb.	1½ c. per lb.
Nitrate of lead.	3 c. "	1½ c. "
Orange mineral.	3½ c. "	1½ c. "
Red lead.	3 c. "	1½ c. "
White lead, and white paint and pigment containing lead, dry or in pulp, or ground or mixed with oil.	3 c. "	1½ c. "
<i>Salts, &amp;c.</i>		
Bicarbonate of soda.	1 c. "	1 c. "
Hydiate of, or caustic soda.	1 c. "	1 c. "
Bichromate and chromate of.	3 c. "	25 per cent.
Sulphate or soda ash.	1 c. "	1 c. to 1½ c. per lb.
Silicate of soda.	1 c. "	1 c. per lb.
Sponges.	20 per cent.	10 per cent.
Straw, and all sorts of reed.	40 c. per oz.	30 c. per oz.
Sulphur, sublimed, refined, or flowers of.	\$8 to \$10 per ton.	20 per cent.
Sesame, ground.	15 c. per lb.	10 "
Tartar, cream of, and patent tartar.	6 c. "	20 "
Tartar and lees crystals, partly refined.	4 c. "	20 "
Reichell salts.	3 c. "	2 c. per lb.
<i>Soap.</i>		
Castile.	1½ c. "	20 per cent.
Fancy perfumed.	15 c. "	35 "
Medicinal.	15 c. "	35 "
Not provided for.	20 per cent.	10 "
<i>Sugar.</i>		
Raw.	Free	40 per cent.
Refined.	1½ c. per lb., above No. 16	10 "
Sugar candy and all confectionery, made wholly or in part of sugar.	5 c. per lb.	35 per cent.

## THE UNITED STATES TARIFF—continued.

	Present Duty.	Future Duty.
Saccharine.	"	25 per cent.
Glucose, or grape sugar.	1 c. per lb.	15 "
<i>Seeds.</i>		
Castor beans or seeds.	50 c. per bush.	25 c. per bush.
Flaxseed or linseed, poppy-seed, and other oil seeds, not specially provided for.	30 c. "	20 c. "
Garden seeds, agricultural seeds, and other seeds, not specially provided for.	20 per cent.	10 per cent.
<i>Miscellaneous.</i>		
Chicory-root, burnt or roasted, ground or granulated.	2 c. per lb.	2 c. per lb.
Cocoa, prepared or manufactured: chocolate, sweetened.	2 c. "	2 c. "
Cocoa butter or cocoa butterine.	3½ c. "	3½ c. per lb.
Dandelion-root and acorns, prepared, and other articles used as coffee, or as substitutes.	1½ c. "	1½ c. "
Starch, including all preparations, from whatever substance produced.	2 c. "	1½ c. "
Dextrine, burnt starch, gum substitute, or British gum.	1½ c. "	1½ c. "
Mustard, ground or preserved, in bottles or otherwise.	10 c. "	25 per cent.
Spices, ground or powdered, not specially provided for: capsaicum or red pepper, unground, and sage.	4 c., 2½ c., to 3 c. per lb.	3 c., 2½ c., to 1 c. per lb.
Vinegar.	1½ c. per gall.	7½ c. per gall.
Malt extract, fluid, in casks, in bottles, or jars, solid or condensed.	20 c. to 40 c. per gall. and 10 per cent.	15 c. to 30 c. per gall. and 30 per cent.
Corks, wholly or partially manufactured.	10 c. to 15 c. per lb.	10 c. per lb.
Matches of all descriptions.	10 c. per gross to 1 c. per 1,000	20 per cent.

The free list is almost the same as heretofore as far as this class of goods is concerned. It comprises nearly all crude drugs not especially named in the list quoted above. Epsom salts and copperas (both hitherto charged with a duty of  $\frac{25}{100}$  c. per lb.) are to be free, and medicinal coal-tar preparations and products of coal-tar not colours or dyes and not specially provided, are also now admitted to the free list. Ginger ale, ginger beer, and all artificial mineral waters are now to be charged at 20 per cent. *ad val.* Hitherto 13 cents per dozen bottles (if not exceeding  $\frac{1}{4}$  pint) was charged on ginger ale, ginger beer, lemonade, soda-water, and similar waters. No additional duty is to be levied on bottles.—*Chemist and Druggist.*

## UNITED STATES.

## Customs Decision.

Binoxide of barium, otherwise known as peroxide of barium, is dutiable at 25 per cent. *ad val.* under the provisions of paragraph 76 N.T.

## GREAT BRITAIN.

## New Customs and Excise Regulations.

An official publication of great interest to the trading public has lately been issued by the Revenue Departments. This is the revised code of regulations governing the deposit of goods liable to duty in Customs or Excise warehouses. In order to prevent the large increase of price to the consumer which would ensue from the payment of a duty at once upon goods liable thereto, such goods, on importation or manufacture, can be deposited in officially approved warehouses, and can remain there until the dealer desires to clear them for home consumption upon payment of duty. The code governing both Revenue Departments, which was first issued in 1880, has just been revised, and all the important alterations which have since taken place are now gathered up in one publication.—*Chemist and Druggist.*

## GENERAL TRADE NOTES.

## SALT DISCOVERY IN TURKESTAN.

According to the *Gazette du Turkestan* a commencement has been made with the working of a rich deposit of salt which has been discovered at a distance of 15 verstes from the eastern side of Lake Kang-Koul, not far from the road going by the heights of Touzgoun and Kizyl-Djik to Mouz-Kol. At the present time the salt is extracted at two places, situated at a distance of from 20 to 25 sagues from each other. At these places the salt appears at the surface of the soil. Borings have shown that the places where the salt appears at the surface form the meeting place of two beds of salt following opposite directions. The bed of salt is two or three archines in thickness.

## BOTANICAL EXPERIMENTS IN INDIA.

The *Calcutta Englishman*, in its issue for the 26th June, has the following note:—

In the Royal Botanic Gardens further experiments were carried on last year in the cultivation of plants of economic value. Reviewing the work of the 12 months, Dr. King says that recha plants still continue to be in occasional demand, and supplies have been issued gratuitously to various applicants. Seeds of coca—the source of the anæsthetic known as cocaine—have also been freely given to various tea-planters, but Dr. King is apparently by no means hopeful regarding the cultivation of this plant. In his opinion, the alkaloid can, from its nature, never come into very extensive use, and the demand for it is at present greatly below the supply. Planters have, however, been tempted by the high prices obtained for batches of coca leaves during recent years, and, in Dr. King's words, they have been led into taking up the cultivation "with more enthusiasm than discretion." Among other economic products, *Cola acuminata*, which produces the kola-nut, was also in demand to some extent, and a few applicants outside of India were supplied with the seed of the bhabar or babni grass. The history of this plant, as one of the principal materials used in the Indian paper-making industry, is given in brief in Dr. King's report. It appears that it first attracted his attention as a possible raw material for paper 25 years ago in the North-West Provinces.

In 1873 he sent home samples to a paper-maker in Scotland, who reported very favourably upon them, and a few years later Mr. Routledge, then a leading authority on paper, to whom specimens were submitted through the India Office, found them to be little inferior to esparto as a raw material. Mr. J. S. Gamble, of the Forest Department, subsequently discovered that this grass is common in the forests of Chota Nagpur, and samples were sent to the Bally Mill, then the only paper-making factory near Calcutta.

The qualities of the new grass were found to be so excellent that it was immediately adopted, and it has since become one of the most important raw materials of the industry. The inquiries that have been received of late from other countries appear to show that India will soon lose her present monopoly in this product. Dr. King points out, however, that for paper-making purposes the Japanese paper mulberry tree yields a fibre far superior to bhabar. His efforts to extend the cultivation of this tree in Bengal, where it can be readily grown, have not hitherto been successful; but the qualities which Dr. King claims on its behalf should ensure its eventual adoption. For the information of those who care to make the experiment, it may be noted that the Botanic Garden has still a small stock ready for issue to any applicant who may be forthcoming. There is obviously much room for improvement in Indian paper manufacture, and the introduction of the Japan paper mulberry tree may possibly enable the mills in the country to approximate somewhat more closely to home manufactures in quality as well as in price.

## LIME-CULTIVATION IN THE WEST INDIES.

There is an interesting note on the West Indian lime in a recent number of the *Kew Bulletin*. The sour lime-tree

(*Citrus medica*, L., var. *acida*, Brandis), which yields the lime-juice and essential oil of lime familiar in the drug trade, was probably introduced into the West Indian islands from the East. Lime-juice is obtained by compressing the fresh ripe fruits between heavy rollers. It is exported in the raw state or concentrated. The concentrated variety is obtained by evaporating the raw juice in copper or enamelled-iron pans until it is reduced to about one-eighth or one-tenth of the original bulk. When exported it is a dark, viscid fluid of the consistence of treacle. From the rind of the fresh fruits there is obtained, by the candelling hand process, a fine essence of limes exported in copper vessels. The process, which is a slow one, is performed by women and girls. The task per day is measured in fluid ounces. By distilling the raw lime-juice a spirit is obtained known as oil of limes. The essential oil of limes extracted by hand is far more valuable than the oil of limes, as the perfume of the latter is injuriously affected by the heat necessary in distillation.

Lime-trees were abundant in Dominica as long ago as 1791, but at that period they appear to have been grown only for their fruit. The lime-juice industry appears to have been started in Dominica by the late Dr. Murray, but shortly after the commencement of that gentleman's venture the Messrs. Sturge, of Birmingham, quite independently of Dr. Murray, and without any knowledge of his experiments, set to work to establish similar plantations in the neighbouring island of Montserrat. The industry appears to hold on prospects of being a remunerative one, for, according to a Dominica planter, it takes about 1,000*l.* to purchase about 20 acres of land and plant them with lime-trees, to build a house for the manager, to erect a mill with copper boilers, to concentrate the juice, to pay for superintendence, and cover all expenses for seven years. At the end of this time the estate would yield 10 hogsheads of concentrated lime-juice a year, worth 480*l.* The yearly cost of cultivation and manufacture would amount to 240*l.*, the rest being gross profit.—*Chemist and Druggist*.

## THE MINERAL INDUSTRIES OF SOUTH RUSSIA.

The official *Messenger of Finances* gives the following account of the mining and metallurgical industries of the south of Russia during the year 1893. The region under consideration comprises the following private works and mines: Eighteen iron mines in the government of Volynia and in the neighbourhood of the villages of Kriviy Rog, one lignite mine in the government of Kieff; five blast-furnace companies, namely, the Denesheffsky, Vugodensky, and Emelchinsky in the government of Volynia, and the Glantselsky Company in the government of Cherson; the Alexandroffsky Iron and Steel Works in the town of Ekaterinoslav, the Briansk and Dnieper Iron and Steel Works in the village of Kamensk, the Iron Works of the South Russian Dnieper Metallurgical Company, also near Ekaterinoslav, and also the Novorossisk Iron and Steel Works at Hughesoffa. The district also includes five manganese ore mines in the government of Ekaterinoslav, 27 coal mines in the neighbourhood of Bachmout, and Karakonsky and Stillsky iron mines in the region of Mariopol, the Auerbach mercury mines and works at Nikitoffka, and 60 coal mines in the neighbourhood of Lugansk. The output of these works and mines during 1893 and 1892 was as follows, in metric tons:—

	1892.	1893.	Increase.
Coal.....	2,025,200	2,159,350	134,150
Lignite.....	2,000	7,618	5,618
Iron ore.....	518,204	625,615	107,411
Manganese ore.....	28,945	70,450	41,505

The quick-silver mines owned by Messrs. Auerbach produced 61,200 tons of ore, from which 443,169 lb. of

mercury were obtained. The iron and steel works report the following output, in metric tons:—

	1892.	1893.	Changes.
Pig-iron .....	267,582	319,176	Inc. 51,644
Manufacture Iron .....	60,349	82,540	Dec. 27,800
Steel rails .....	110,900	133,774	Inc. 22,874
Other steel .....	29,350	27,360	Dec. 1,990

In the Donetz basin the coal industry continues to develop, but in 1893 the local demand for coal considerably exceeded the supply; this is partially explained by the abundant harvest of that year having claimed the coal miners, who are really peasant proprietors, for a longer period than usual, and also by the ravages caused by the cholera. The dearth of coal somewhat impeded production at the metallurgical works of the district.

The rapid development of the iron and steel industries of the south has evoked a corresponding growth in the production of iron ores. The exploitation of the manganese mines also shows remarkable progress. Notwithstanding the temporary check caused by the dearth of coal, the total production of pig-iron in the south of Russia shows an increase of 18 per cent., and of rails 20 per cent. over that of the preceding year.

In April 1893 the Donetz Iron and Steel Company started building new works, and at the close of the year had erected one blast-furnace with a production of 10,000 pounds (163 tons) of pig per day. The furnace is 65½ ft. high, and is furnished with four Cowper hot-blast stores. Attached to these works is a Schuterman and Cramer coal-washing plant capable of dealing with 325 tons of coal per day, and a set of 12 Bernard coke-ovens with a capacity of 81 tons of coke per day. The Alexandroffsky works have also erected a new blast-furnace, No. 4, with three Whitwell stoves, and a set of 62 Coppee coking-ovens, besides which they have supplemented their Bessemer and rolling plant with hydraulic machinery, and lastly, both the Dnieper and Novorossisk have added a fourth blast-furnace to their plant.

In 1893, 36,872 men were employed in the mining and metallurgical industries of the south of Russia. This total was distributed as follows:—13,322 in coal mines, 1,718 in iron mines, 895 in manganese mines, 298 in mercury mines, 12,618 at iron and steel works, 236 at mercury works, and 7,785 in quarries. There were 206 accidents, 80 of which were fatal.—*Engineering and Mining Journal*.

#### NATURAL MINERAL WATERS.

The Academy of Medicine has unanimously adopted the report of the Committee on Mineral Waters, presented by M. Albert Robin. There were only two members present. The recommendations are:—1. The sale of mineral waters which have been decanted or artificially rendered gaseous should not be allowed by the authorities. 2. Every application to the Ministry for authorisation should be accompanied by the certificate of a competent official that the water has not thus been already manipulated, and should embody the promise of the proprietor not to resort to these processes. 3. Reservoirs should be hermetically closed, and should be emptied at least every twenty-four hours. They should be so placed that the spring flows direct into the reservoir. Bottles should be thoroughly sterilised, and all causes of pollution during bottling carefully avoided. 4. Notice of these new arrangements should be sent to the proprietors of all springs already authorised, and three months should be given them to conform therewith.—*Chemist and Druggist*.

#### THE EXTRACTION OF NICOTINE FROM TOBACCO-LEAF.

The Government Tobacco Monopoly are giving this subject attention, and they claim to have succeeded in obtaining a product of high concentration and uniform quality. They think there will be a large demand for it for the destruction of insects in agriculture and horticulture, and also from South America and other sheep-raising countries as a

remedy for scab. Several millions of pounds of nicotine are annually sold in Uruguay and the Argentine Republic, but the quality is very variable. M. Frayssé, a Buenos Ayres merchant, after making two journeys in the countries in question, with a view to thoroughly studying the matter, has just been appointed special agent of the French Government for the sale of the product at Rio de la Plata. The Government process has been devised by M. Schlossing.—*Ibid*.

#### CHEMICAL CONGRESS.

It is announced that the International Congress of Applied Chemistry, which has just terminated its session for 1894 at Brussels and Antwerp, will hold its next meeting at Paris in two years time. The Association of French Chemists of Sugar Refineries and Distilleries is to be charged with the organisation of the congress in 1896. At the one just terminated M. F. Dupont, a French delegate, brought forward a proposition for the adoption of the French metric litre, to the exclusion of the Mohr or German litre, as a base for gauging and for the graduation of chemical instruments, which was unanimously carried. The French Centigrade thermometer was also adopted by the delegates in preference to the Réaumur or Fahrenheit thermometers.—*Ibid*.

#### THE ANNUAL REPORT (EIGHTEENTH) OF H.M. INSPECTORS OF EXPLOSIVES FOR 1893.

See under XXII., page 837.

NOTE.—With reference to the letter from the Home Office, published in the June No. of this Journal, p. 674, it will be seen from the above report that the authorities have reconsidered their determination to treat collodion cotton as an explosive.

#### THE COKE PROBLEM IN ENGLAND AND AMERICA.

Mr. Jos. D. Weeks, of Pittsburgh, one of the leading authorities in the United States on natural gas, petroleum, and coke, was recently commissioned by the American Geological Survey to make a report in his official capacity as the expert on coke of the United States Census. He was accompanied by Dr. F. L. Slocum, Pittsburgh, a well-known chemist and gas-train expert; Mr. J. L. Gardener, gas-expert; and Mr. Wm. Stanton, firebrick manufacturer. The by-product coke-works in this country, which have been visited, have included, among others, the following:—The West Crook works of Pease and Partners; the works and furnaces of Sir B. Samuelson, M.P.; the works of the Durham Coke and By-products Company, Lanchester; the works of the Brymbo Steel Company; and the works of Brunner, Mond, and Co. (Limited), at Northwich, near Liverpool, where the Smet-Solvay ovens are erected. The Belgian by-product works have included the Havrèville and Bois du Lac collieries, belonging to the leading coal company of Belgium, and possessing the deepest pits in the world (over 1,000 yards); and the Seraing Collieries of the celebrated John Cockerill Company. In Westphalia the concerns were the great Krupp works at Essen; the Constantin collieries, No. 11; the Germania collieries; the Julia collieries; and the Recklinhausen, No. 11, collieries. At all these the Otto-Hoffmann ovens are in use. Admission was also obtained to the Phoenix Coke-works at Ruhrort, the Hussener works at Gelsenkirchen, the Shamroek works near Bochum, and the Osterman works at Bochum—at the two latter of which beehive ovens are still in existence. On the question of yield and of by-product recovery, Mr. Weeks will report that the yield of coke is much larger by the close than by the open method of manufacture, and that the proportion of by-products recovered is about as follows:—Sulphate of ammonia, rather over 1 per cent. in weight of the coal charged; tar, 2½ to 3½ per cent.; and benzole, from ½ to 1 per cent., or slightly more. These by-products yield, after paying the expenses of condensation plant, a profit of from 2s. to 3s. and on to 4s. per ton of coal consumed. Regarding the alleged deterioration in coke for blast-furnace purposes, which has been subjected to the recovery processes compared with that made upon the beehive-oven principle, Mr. Weeks' report is likely to be definite. Although at first, in both Belgium and Germany, a prejudice existed among certain of the pig-iron making firms in this direction, no such prejudice exists now. The excellence to which the

close processes have been brought seems to have completely settled this question. The ironmasters of both countries are now convinced that the weight-bearing and heat-giving qualities of the coke are not deteriorated by taking out the ammonia, tar, and other waste products, and the retort fuel is regarded as in all respects as good for ironworks' uses as the beehive product. The almost complete manner in which the retort has superseded the beehive oven in Belgium and Westphalia—two of the leading ironmaking countries of the world—is, indeed, in itself, evidence sufficient on this point. After a most painstaking enquiry, in the course of which they have accumulated a vast amount of information, the party have come to the conclusion that there is nothing to prevent, but everything to recommend, the substitution of the retort and by-product oven for the beehive oven now almost exclusively used in America. Care is, however,

needed in building the ovens to proportion, their design and parts to the exact character of the coal to be used. For example, most of the coking coals of the great Connellsville and some other of the coking districts of America are superior in volatile matter to the European fuels, and the same applies to the coking coals of this country. Other points of difference might also be mentioned, which will have to be taken into consideration by American builders of the new retorts. A necessity also exists at the by-product oven for a more careful and intelligent management than is required in the beehive. It is declared to be almost impossible with the beehive oven to make bad coke from good American coal, and little supervision in the actual carbonising of the coal is required. In the case of the retort or by-product ovens, however, increased supervision must be exercised by the responsible oven-manager.—*Ironmonger.*
